Taking the country at large, it cannot be said to be unhealthy, it being a well-known fact that the great epidemics have never caused the number of victims in Peru as they have elsewhere. Cholera has never appeared in Peru, though it has raged very severely in the neighbouring countries. Yellow fever, that great scourge of nearly every tropical climate, has paid Peru few and far-between visits, but even then its number of victims compares favourably with those of other countries; and, what is more important, its last visitation, in 1881, was of small duration, and compared even more favourably with 1868 than that year's did with the great plague of 1854.

In some of the valleys there is, to a great extent, a sort of ague called *terciana*, arising principally from the marshes, but this illness cannot be considered as a serious one, and now it is generally combated with undoubted success by the most insignificant of local practitioners.

If old age is a test for a country's salubrity, then it must be confessed that Peru is really healthy, as not only amongst natives do people attain a ripe old age, but many foreigners, settled in different parts of the country, have lived to ages considerably above sixty.

Accepting the salubrity of the country and its suitability for Europeans, the first and natural question which arises is, to which zone of this country should Europeans go?

In order to answer this, I must first give an account of the natural resources of each zone, or, at least, of the Costa, Sierra and Puna, and Montana, as I do not suppose anyone would choose the snow-covered peaks of the Andes, the Cordillera zone, as a likely place to emigrate to.

By reason of the climatological and geological conditions of Peru, likewise of its great heights, distribution of the waters of its great rivers, and aridness of its coast, the three kingdoms—animal, vegetable, and mineral—are represented in each and all of the zones by special characteristics, which constitute of themselves undeniable sources of wealth.

The animal kingdom is represented in the Costa by the following live stock:—Horn cattle, goats, horses, mules, donkeys, wool-bearing animals, pigs, various breeds of dogs, deer, rabbits, vizcachas (a kind of hare), cats, and others. There are also partridges, pigeons, cuaresmeros (a kind of ruff), and many other game birds, as well as ducks, geese, turkeys, fowls, innumerable sea birds, and a great variety of good fish, both of salt and fresh water, the principal being *corbina*, which is one of the best fish extant; the *pejerey*, King Fish, an extra superior quality of smelt; *camarones*, *bonito*, *raya*, *pampano*, *lenguado*, *lisa*, and others, which are more or less familiar to Europeans as prawn, skate, sole, plaice, and haddock.

In the Sierra and Puna there are the vicuna, huanaco, llama, alpaca, all wool-bearing animals; also tigers, bears, wolves, panthers, jaguars, and other wild beasts; condors and other birds of prey. In the lower parts of the Sierra large stocks of cattle and sheep are raised. The animals found in the Montana are a variety of wild beasts; also horses, cattle, pigs, deer, rabbits, and wild hogs; the chinchilla, the nutria, and other fur-bearing animals; turkeys, pheasants, ducks, fowls, pigeons, geese, birds of paradise, and as great a variety of humming birds as are to be found in any part of the world, game birds unknown to the European; and also a large variety of reptiles, alligators, and fish of many kinds in the full flowing rivers. The *fauna Peruviana* has been well studied by Professor

William Nation, an Englishman, who has lived in Peru for a great many years. Up to 1881 he had catalogued 40,000 different specimens, including birds of passage.

The vegetable kingdom of the Costa has as principal products—sugar-cane, rice, cotton, bananas, maize, vine, alfalfa (a kind of lucern, or luxuriant clover), olives, tamarinds, potato, and sweet potato, all kitchen vegetables, and every kind of tropical fruits, as well as other indigenous ones.

In the Sierra, the products of the temperate zone, and many of those of the torrid zone, are cultivated; and, in fact, anything and everything may be cultivated in this privileged region. However, its principal products are potatoes, a plant indigenous to Peru, which grows wherever planted, and even in a wild state. The primitive potato is about the size of a hazel nut; and it is to the aborigines of Peru, who, by careful cultivation, developed it, that the world owes one of its principal food-roots. Wheat, barley, oats, alfalfa, maize, or Indian corn, which grows nearly everywhere, and, in some places, yields two crops a year. It supplies a staple of life for all classes, and not only affords food, but serves to make the national beverage, *chicha*. Yucca, rhea, or ramie, tobacco, coffee, cocoa, chinchona, cane, castor oil plant, and a very large variety of fruits, grains, and medicinal plants grow, wild and cultivated, in this zone.

The principal staples of the mountain are caucho, or india-rubber, which is exported *via* Brazil, by the river Amazon, tobacco, sarsaparilla, ivory-nuts, chinchona, coca, coffee, cocao, cane, and every tropical product known. The forests abound with valuable timber, woods, and plants, among which are found rare wood, for cabinet work, medicinal and oleaginous plants, dye woods, and textile plants.

On the cold, bleak Puna, the few crops that grow are the ichu, on which the wool-bearing animals indigenous to this region feed; barley, oats, quinua, olluco, oca, and other indigenous roots, which the natives use as food and for medical purposes.

Rich as the agricultural wealth of Peru is, it is as nothing when compared with the resources of the mineral kingdom. Providence, with a lavish hand, has hidden away in those great ranges of mountains which form the Andes, and, on their slopes, both eastern and western, as in the sandy hills and plains of the coast, and in the beds of the torrents and rivers in the Montana, all and every description of minerals, fossil substances, oils, and even precious stones.

The Costa is rich in petroleum, silver, copper, coal, sulphur, salt, guano, nitrate, lime, magnesia, borax, and gold is found in many places.

The Sierra is undoubtedly the region where the great mineral wealth of the country lies. The Andes can be said to be the gigantic monument raised by the hand of Nature to Mammon. Within those mountains are hidden the treasure which many struggle for; it was the sight of those treasures which made Spain, that great power of the 16th century, destroy an ancient empire, and cause to disappear a civilisation the like of which had never been seen or heard of. And yet to-day, when we come to consider that Spain during three centuries only managed to scrape the surface of those rocks, notwithstanding the fact that the value of the silver which the conquerors extracted amounted to something like £180,000,000 sterling, it shows how remarkably rich the country is; none of the mines having been worked on a very large scale, owing to the backward state of the mining industry in those days. It is believed by mining experts who have visited some of the principal silver districts of Peru, that the amount of high grade ores extant, nearly on the surface of the mines, or which can be extracted at a small cost, amount to considerably over 2,000,000 tons, while the poor or low grade ores which have been piled outside the mines worked by the Spaniards, and which, with modern appliances, could be treated with undoubted success, represent many hundred of thousands sterling. The Peruvian press and the Peruvian miners at large have lately been much excited over an invention of Senor P. F. Remy, a Peruvian mining expert, who professes to have found a new method for the treatment of blende, one of the most refractory ores, and which abounds greatly in Peru. Until now miners did not know what to do with such ores, the result being that they were turned aside and left there; but to-day, when Mr. Remy affirms that he has discovered the means of turning such ores into account, Mr. Gamboni, an Italian mining expert, challenges the priority of the invention, and actually states that he has an invention of his own for the treatment of the same ores. Both methods give the same result, but they differ one from the other in detail. According to last accounts it appears that Senor Remy proposes that an independent committee should study both pro-

cesses, and that its decision should rule. Mr. Gamboni does not accept this, claiming that when Mr. Remy applied for his letters patent, he had already patented his invention, and he further argues that Mr. Remy's so-called invention is only an application of his own.

But I have digressed from my main point. To return to my subject, I will just name the principal minerals which are to be found in the central region of Peru:—Silver, copper, gold, lead, cobalt, cinnabar, antimony, coal, salt, iron, nickel, marble quarries, arsenic, sulphur, alum, and petroleum.

In the Montana the gold washing and gold mines are the special feature; there are also known to exist emeralds, rubies, turquoises, and diamonds, in the eastern rivers, as the Incas used such precious stones to adorn their garments with.

By the preceding enumeration of the resources of the three kingdoms, it is obvious that Peru has been favoured with more than an ordinary share of the good things of this world, which, from a commercial and practical point of view, constitute a nation's wealth.

Undoubtedly few countries on the face of the globe can present a higher standard of natural resources, and, much less, can any present such resources placed in more suitable localities for the ends of commerce. When we consider the geographical position of the nitrate fields of Peru, the guano deposits, the immense petroleum fields, which lie on the sea coast inviting the hand of commerce and enterprise to carry them across the seas to less favoured climes, and we turn our minds to the agricultural resources and find that, notwithstanding the great and natural barrier which divides the coast from the Montana, each zone is favoured with outlets for the exportation of their large and varied products, on one side the Pacific Ocean, and on the other the great navigable rivers which empty their waters into the majestic Amazon, which flows into the Atlantic, it is impossible not to recognise the fact that we have before us one of the most favoured countries of the earth, and one which, if not to-day, to-morrow will force itself upon all men of enterprise.

To some, this may appear exaggeration. You may be inclined to think that my enthusiasm carries me away, or that in my earnest endeavour to serve my country, I trespass upon the limits of your credulity and overrate its resources. If all what I have said had not been already proved to the world at large by distinguished Englishmen and others who have visited the country, I might, indeed, be taken for an optimist, but, fortunately for Peru, and I may say for the commercial world, every one of my words can be confirmed by independent evidence.

Little wonder, then, that this country, notwithstanding the many drawbacks which have served as obstacles to its greater development, should be to-day attracting the financial world in such a noticeable manner as it does, and that it should be considered by many as the land of promise for the overgrowing population of European countries.

Judging from the description which I have just made, you will come to the natural conclusion that Peru offers, in each and all of its different zones, an ample field for enterprise; and that, therefore, the European, from a climatological and commercial point of view, could suit himself in no matter what part of the country.

Undoubtedly this is a fact; but I beg you to bear in mind that, while some parts of Peru have been more or less opened up to commerce and industry, there are others equally as rich, if not richer, where the soil is completely virgin, and where the skill and energy of the European is more necessary than in others. I refer to the transandine region; that is, the eastern slopes of the Great Cordillera and the Amazon Valley.

The coast has in itself the necessary elements to be self-supporting. This region has been more or less in actual development since the Spanish domination; and although there is a great scope for the advancement of its industries—notably, the agricultural—still it keeps apace with the general progress of the country. What the coast mostly requires is irrigation and the aid of capital. Its now seemingly arid plains can be turned into rich agricultural lands at a comparatively small cost; and these, properly cultivated, will produce abundance of crops, which will, within a short period, repay capitalists investing in such an enterprise.

The sugar, cotton, rice, and vine plantations of the coast could all be made much more profitable, and the production of these, the principal crops of this zone, could be increased within a very short time, if the owners of the estates had the necessary capital to invest in their properties. Unfortunately, many of the owners of the fine cane estates are in very straitened circumstances, owing to the present low price of cane-sugar in the European markets, and the heavy losses which they sustained during the war with Chile, when the whole trade and

commerce were paralysed, and to the general depression which followed closely upon that event. Another by no means unimportant factor for such a state of affairs has been the scarcity of labour, which, ever since the importation of Chinese contracted labourers was suspended, in 1875, has caused great prejudice to the agricultural interests at large; and last, but not least, the extravagant manner in which they commenced their business, the costly plant erected, and the anti-economical methods of production employed.

The valleys of the coast, as well as these sandy plains, must all, sooner or later, become great industrial and agricultural districts; and there is already a marked tendency in this direction, traceable to the last few years. Several schemes for the irrigation of these lands are now under consideration and study, and a few of the best estates are being worked on a larger scale than they have hitherto been. The prospects for the coast are even brighter; and, what with the recent discoveries of vast and rich fields of petroleum along the northern coast, this zone has every possible facility for attaining greater prosperity.

The depression in Peruvian agriculture dates since the abolition of slavery, in 1854; this most humane step having been taken during a civil war, and when one of the contending parties was in dire want of fighting men. Until that year the estates and plantations of the coast had been worked by the descendants of the African slaves, who had been imported into the country for the purpose by the Spaniards. These negroes, although a lazy lot, managed to work the plantations fairly well, and there is no doubt but that, up to that time, agriculture was a thriving industry in Peru. During this civil war, the greater part of the slaves were turned into soldiers; and once they had tasted the cup of military idleness and town life, they were incapable of returning to a country life and agricultural work. The cotton, sugar-cane, and vine estates, which constituted the agricultural wealth of the nation, were nearly abandoned, thus causing great losses. Each new citizen considered himself equal to his late master, and used the freedom which law had granted him in a most injudicious manner. As if this were not sufficient, Providence willed it that about that time Peruvian guano should be brought to the notice of Europe, and the suddenness of the springing up of this new and extraordinary source of wealth was the cause of the complete neglect of all agricultural interests in Peru. The nigger soon degenerated completely; country life had no longer any attractions for him and his, he yearned after the pursuits of the whites, he learned trades and even professions, and lived in the populated centres, leading, in most cases, a vagabond life; as a soldier he was a perpetual source of trouble and danger to the Government, the *pronunciamentos* having generally their origin from among the coloured troops.

When the agriculturists of Peru found themselves in such a sad plight, they considered what had best be done in order to save the country from becoming less and less productive, through the want of proper cultivation and care, and they, therefore, sought aid from the Government and implored for labourers. The Indian was entirely unfit for such work on the valleys of the coast, where the principal estates and farms were situated. The black and his cross breeds could not be induced to return to a life which reminded them of slavery; and so there was really nobody to do the work. It was then that immigration for agricultural purposes was first thought of, and the first idea was to get Europeans, but having failed to get sufficient supply of these, Chinese labourers, which had proved successful in other countries, were got instead. From 1856 until 1873, if my memory fails me not, whole shiploads of Celestials arrived yearly in Peru. At first very few were forthcoming, but, between 1869 and 1873, their numbers greatly increased, and there were as many as 13,000 imported in one year. These labourers helped in a great measure to revive the agricultural interests of the land; they were contracted for a period of eight years, during which time they were obliged to work for their employer, after which they were free to dispose of their labour. As a result of the impulse which agriculture received at the time, it is well to note that in 1870 Peru exported to this country 251 tons of raw sugar. In 1873 this quantity had grown into 15,950 tons, in 1875 into 50,000, and in 1879 into 71,400 tons. This was the year in which the war with Chile broke out, and, as a sequence to the misfortunes which befell the country, the exports of this most flourishing industry naturally fell in 1880 to 49,503 tons, and in 1884 to 26,565 tons. Since then a favourable reaction commenced to set in, the exports of sugar during each of the last two years to this country having averaged 42,500 tons.

Notwithstanding the immigration of Chinese

labourers, the Government have ever been trying to obtain a good and constant supply of Europeans, and towards this, several laws have been passed by Congress, and now and again contracts have been entered upon with different companies and persons for the introduction of European labourers into the eastern regions of Peru. A few colonies or settlements have from time to time been established within the territory composed of Germans and Italians; but, for the most part, the Europeans who have gone to Peru in order to seek a living, have given themselves more to trade than to agricultural pursuits, so really Peru, in this respect, may be said to still present an entirely new field for European enterprise.

The Sierra which, as I have said, is mainly dependent on the mining industry for the support of its inhabitants, like the coast, requires the aid of foreign capital, in order to achieve that development which its extraordinary mineral wealth demands.

The aboriginal who inhabits this part of the country is of a stolid nature. He dislikes agricultural work, which is generally attended to by his wife and female portion of the family, while he toils at the mines. It must be borne in mind that, as the Spaniards obliged all the Indians and their families to slave at the mines they have become accustomed to this kind of work; and so every *serrano* is, by instinct, a miner. He is, as a rule, very quick at learning all practical knowledge proper to his vocation; and, now that the Government have established miners' training schools in all the principal mining districts, he is developing a great and natural taste for skilled work. If that horrid *guarapo*, made from the juice of the sugar-cane, could be banished from the mining centres, in spite of the many drawbacks which have, since time immemorial, served to degenerate the descendants of a once powerful and civilised race, the *serrano* could yet be made an important factor in the greater development of his country. Unfortunately, the use and abuse of this stuff is ever on the increase; and, while its manufacture enriches a good many cane growers and distillers, its effects are fastly ruining a large section of the population. Perhaps, when the country, and its many other resources, are properly worked, new industries will spring up, more thriving, and decidedly more honourable, than the one which, as a Peruvian, I have to deplore, on account of its pernicious effects.

The greater part of the land in this region is owned by the natives themselves. Their wives till the ground, and grow maize, yucca, potato, and other indigenous plants and roots on which they mainly live. It is due to these great facilities of existence which they have, that the *serranos* are so careless of everything and so little ambitious; but it is to be hoped that, with the spreading of education and the bringing of these regions into closer contact with the commercial and industrial centres where the whites abound, that a change will soon take place beneficial to them.

At present, the number of mines which are being worked in Peru are comparatively few, when compared with the numbers during the Spanish domination. At that time, every available man and woman was sent to work at the mines. Since the War of Independence, the mining industry of Peru has suffered a great deal, and when the guano fever set in, hardly anybody thought of that which had made famous the name of Peru.

To-day, the same as in the agricultural interests, there is a reaction in favour of mining, and every year this industry receives new life and vigour. Its final development will depend on the interest which it may attract from the foreign capitalist and speculator.

The trasandine region, or Montana, where everything is exuberant, and where the hand of industry has not yet commercially developed the products of nature, is beyond dispute one of the most favoured fields for European enterprise. It is to this virgin region where I would convey you in imagination. Just fancy, for one instant, a region where grow in luxuriance, such valuable products as tobacco, sugar-cane, rubber, cotton, coffee, cocoa, vanilla, sarsaparilla, copaiba, the vine, oranges and other fruits, herbs and plants, both medicinal and oleaginous, timber and wood of every description; where the rivers are navigable, and on the banks of which some of the richest gold, and diamond, and emerald, and ruby fields are to be found. If this does not come to the expectation of the "El dorado," or does not realise as near as possible the tales of the "Arabian Nights," I do not know what does. And yet this is not a myth, neither is it the dream of a writer of fiction. Mr. Louis Wolff, a German engineer, who has only last year been exploring the valley of the Peruvian Amazon, says that it is his opinion that the gold washings of the Maranon and other rivers, if worked by the hydraulic system, would yield very great quantities of the precious metal. He urges that the Peruvian Government should send a

scientific expedition to the River Santiago, in order to make a proper survey of these treasures.

Many other Europeans and Peruvians, who have visited that part of the country, speak of its extraordinary wealth; and all who have been there feel surprised that it should not have attained a greater prosperity already.

The Government of Peru, fully convinced of the importance of this region, appointed a Special Commission to report upon it. Their report, which is a most elaborate one, and which does honour to the Commissioners, contains many valuable details with respect not only to the resources of the region, but with respect to its many requirements. Among other innovations which they recommend, perhaps the establishment of an Agricultural College and of a Bank of Agriculture deserve the most attention, as they would both be the best means of furthering the plans of the Government. The port of Iquitos, on the Amazon, from whence the products of this region are brought to Europe, carries on a very active and increasing trade with the outer world, and is called upon to be, at a not distant period, a very flourishing port.

Of the trade of Peru through the Amazon very little is known in this country, for the simple reason that all the Peruvian products exported, specially rubber, sarsaparilla, ivory-nuts, tobacco, and copaiba, are generally classified among the exports from Brazil. The steamers which navigate the River Amazon and its principal affluents are all Brazilian, and at the Brazilian port of Para these exports are transferred to the larger steamers, which cross the Atlantic and convey them to Europe. In view of this, the Peruvian Government have been authorised to offer a subsidy of $12,000 per annum to any steamship company which would undertake to run a regular line of steamers between the Peruvian rivers and the European ports.

As an item to any who may wish to study such a scheme, I will point out that the annual exportations from Iquitos amount to about 1,000,000 kilogrammes, while the value of imports represent about 1,000,000 soles silver. Besides the rubber trade, there is every facility for the carrying on of a large business in timber and cabinet woods. And from what I learn from this region, I consider that the erection of proper and modern sawing mills would prove a highly profitable venture.

I trust that I have been able to prove to you that immigration on a large scale into the interior of Peru would be the means of opening up a very rich country. That this is commercially practicable and profitable there is not the least doubt, as the products indigenous to the region, and those which can be cultivated, are of such value, and of every day increasing demand in the European markets, as to ensure the success of the enterprise; whilst the mineral wealth is next to inexhaustible, and the pasture lands so extensive, that any amount of cattle and domestic animals may be raised. I take it that you are all aware that, since the conversion of the old Peruvian external debt, the Peruvian Corporation, which was formed in order to take over the several concessions which Peru made to the bondholders, has sent several Commissions to Peru, with a view of studying the agricultural resources of the country, for the purposes of establishing European settlements or colonies on the large tracks of land which have been ceded to them by the Peruvian Government.

Some of these Commissions have now returned to England, and reported upon the country they have visited; and I am glad to see that they, more or less, endorse all my views on Peru as a field for enterprise. It is their opinion that the country is admirably suited for European immigration; and Mr. Clark, of the Royal Botanical Gardens of Ceylon, on this subject, says:—"With a climate of such salubrity and adaptability to a European settlement; a soil of exceptionable fertility; an immunity from most of the parasitical plant pests; the tropical products found, with an adaptability to the introduction of other economic plants, which have proved so important to the development of other countries; together with the opening up of the country, by means of improved transit, I have every confidence in the future prosperity of tropical Peru." It is, therefore, to this region that the European should go; and, by developing this part of the country, he would carry prosperity to the country at large. The railways already constructed, those in construction, as likewise those under survey, will all help to attain this end. These lines will place the Montana regions and their great arable lands in direct communication with the mining centres and with the coast. The interchange of products will give life to many new industries; population will be on the increase; fields of cultivation will extend; and, by the waterways of eastern Peru, and, by the Pacific, from its western shore, will be brought to

Europe the great and varied products of that country, whose name during centuries has been a by-word for riches. But whilst, in bygone days, such a name only referred to the mineral kingdom, in the near future it shall also refer to the agricultural wealth, which, above everything else, constitutes the life of a nation; a wealth on which it can well repose, and, by so doing, dedicate its newly-acquired energies to the further development of its other many resources.

I am not too sanguine by nature, and have been more of a pessimist than an optimist as a rule, in judgments and calculations, but I must confess that within the last two years I have grown more confident of my country's future; and I look upon you, the English nation, as the restorers of our former prosperity. Notwithstanding our financial default, you still come to our succour, and tend us a helping hand in the moment of need, and with that great energy so characteristic of your race, and which has expanded the limits of this little island until nothing can compare with it on the face of the globe, you now carry the standard of commerce and enterprise into the very heart of the old Inca empire, thereby serving the aims of civilisation.

Well, you may be certain that we all feel quite grateful for this, and that it is our desire to help you in the carrying out of such a grandiose enterprise.

In the foregoing paragraph I say that we mean to be grateful, and that it is our desire to help the British public in carrying out their schemes with respect to the development of our country. In order to do this, the Government have passed through Congress many most beneficial laws for the promotion of mining and agricultural pursuits. Education, which I may consider as the most powerful auxiliary of progress, and the main lever for raising a nation's social standard, meets with every support at the hands of the present administration. To-day, in Peru, besides the Government, municipal and private schools, which are kept up throughout the whole country, there are special establishments supported by the Government, where people of both sexes are taught some craft or other; schools of arts and sciences are being organised in different parts of the territory, and as I have already mentioned, there are good mining and engineering colleges, and schools for *capatazes*, overseers. A central agricultural college is already under consideration, and it is intended that in the agricultural districts special schools for the promotion of agricultural knowledge shall be established.

Import duties on machinery for agricultural, industrial, or mining purposes have been abolished; tools and implements for the same purposes are free, and so are many of the principal articles which serve for the promotion of industry.

Roads and means of communication are being established in different districts so as to bring the far off regions into closer and easier contact with the commercial or industrial centres. Telegraphic communication is fast extending throughout the country, and the navigation of the rivers of the interior is receiving the special attention of the Government. Already the road from Tarma to the tropical forests of Chanchamayo places Lima within 36 hours of that rich portion of our territory. While the roads to La Merced, San Luis de Shuaro, and to the banks of the Pichis and Paucartambo, bring the Montana within easy access of Lima, and open an interoceanic communication from the Atlantic through the Amazon and its affluents, and overland to the Pacific.

Nearly all the railways of Peru are in the hands of the Peruvian Corporation, Limited, and the extension work on some of the more important lines is being carried on with great energy.

The economical condition of the country is progressing, slowly but surely, as a glance at these figures will prove. In 1888 the revenue derived from Customs duties amounted to \$4,361,304·37, in 1889 to \$4,748,790·32, in 1890 to \$5,698,906·38, an increase of \$950,116·60 over 1889, and \$1,337,602·1 over 1888. The totals for last year are not yet to hand, but by comparison with the first six months of 1890 they show again a decided improvement for 1891. Other sources of revenue such as taxes, post and telegraphs, stamped paper, &c., have also been on the increase. The estimates for the current year of 1892 show a revenue of \$7,103,887·64 and \$6,012,617·10 for expenditure, leaving \$1,091,806·04 to meet possible contingencies and a paper superavit of \$708·84. The estimates do not include the special revenues applied to special services, such as are derived from the leasing of the tobacco, opium, and alcohol monopolies, the mining royalties, and all municipal duties and contributions, all of which represent over \$500,000. Peru has to-day no external debt, her internal indebtedness amounting to about £500,000.

The banking system of Peru is carried on by

the Banco del Callao, which has branch offices in several of the principal towns, the London Bank of Mexico and South America, and the Banco Italiano. There is no paper currency at present in the country, the silver sol, the value of which fluctuates according to rate of exchange and to the price of silver, being the standard coin of the country. It is a large piece of silver of the size of a double florin. The Banco del Callao issues a sort of "token" to bearer which circulates freely in the country.

I think that Peru requires a privileged Bank of Issue with a special charter, on the lines of that of the Bank of England, and I am confident that if a group of English bankers of repute were to make an offer to the Government to establish such a bank, the thing would be immediately taken up and studied in Peru, as everyone feels the necessity of such an establishment; more especially the agriculturists and miners, who are in sore need of capital in order to increase their productions. It is true that the banks, specially the Banco del Callao, do advance money on mortgages of real estate; but this is done at a high rate of interest, and for comparatively small sums. The Lima Mint, which is as fine a one as is found in South America, during 1891 turned 1,466 silver bars (the production of native mines), weighing 73,469,230 kilogrammes, into coin, the value of which was $3,100,201·67 in Peruvian currency, about half a million stirling.

Peru being a producing country, and its principal and staple products having a ready market in the European industrial countries, it is not to be wondered that, from a manufacturing point of view, the country should be still backward. Thus it is that, notwithstanding the fact that it produces the best cotton and wool in existence, it imports yearly for the value of about $3,000,000 of cotton goods, and $2,000,000 of woollen goods; while the exports of the raw materials amount to about $2,800,000 for cotton, and $3,500,000 for wool. These exports can be greatly increased; and no doubt will be according as the country progresses.

If the irrigation schemes are carried into effect, the coast valleys will soon produce a tenfold of what they do now; and as the quality of the Peruvian staples are reputed among the best in existence, ready markets would always be found for the greater production.

With respect to the Peruvian wool-bearing animals, I have only to say that their wool is of such a very superior quality, that it commands the highest prices in the market; unfortunately, this high price has caused as yet a limited demand, but I have every reason to believe that if the raising of these animals was to be carried on in the same economical and practical manner to be met with in the Australian sheep runs, the same success which this industry has obtained there would be obtained in Peru.

The textile industries of Peru are yet in their infancy. At present there is a manufactory of woollen goods in Lucre, in the Department of Cuzco. This manufactory dates since 1864, and has given a very large fortune to the owners, Messrs. Garmendia and Company, natives of Cuzco. Their idea was to manufacture the coarse woollen materials used by the native Indians of Peru and Bolivia, and also to supply the materials for the uniforms of the armies of both countries. This they have fully obtained, and there is an ever-increasing demand for their goods, both in the South of Peru as well as in the Bolivian markets.

As the estate of Lucre is situated in one of the best and most thickly populated districts of Cuzco, and where the best qualities of wool-bearing animals abound, the goods manufactured there are far superior to any similar European goods, owing to the fact that at Lucre only the pick of the wools is used, and such as is not exported to Europe. During the year 1890, Messrs. Prado, Hnos, and Pena established a wool manufactory at Lima, which, since then, has given every satisfaction, both to that firm and the general public. The machinery was built by the Societé Anonyme Vervetoise, and is quite modern—"self-acting" spinning-machines, and other smaller machines, are of English make.

The Vitarte Cotton Mill, situated seven miles distant from Lima, in a cotton-growing district, was formerly the property of a Peruvian gentleman, who sold it last year to an English company—"the Peruvian Cotton Manufacturing Company, Limited." The original fitting consisted of 65 looms, producing 1,000,000 yards of cotton cloth per annum; and, since the English Company took over the property, and invested large sums in fitting up 103 new looms, and erecting the latest and most improved modern machinery, the output has risen to 2,500,000 yards per annum of cotton cloth, besides great quantities of cotton wicking, waste, duck, towels, table-

cloths, &c., &c. This mill is to-day as well equipped, and is as complete a concern as the best mill of a similar kind in this country. The demand for the Vitarte goods has always been in excess of the supply. The entire production is disposed of in Lima to local buyers as fast as it is turned out. Owing, as I have already pointed out, to the superior quality of the Peruvian staple, the goods manufactured at Vitarte are better and more adaptable to the native requirements; and thus it is that they always maintain their briskness, and that their demand is ever on the increase, notwithstanding the fluctuations of the market with respect to the imported article, which has to pay a comparatively heavy import duty of between 8 and 24 centavos per kilogramme.

The valleys of Ferrenafe, Chicama, Guadalupe, Santa, Supe, Canete, and the Lima district are, perhaps, amongst the most famous for the cultivation and production of the cane. In these valleys the estates are simply superb, and the greater part of them are fitted up with machinery of the latest and most modern type. The sugar industry in Peru has suffered to a very large extent, owing to the keen competition of beet sugar in the European markets, and the increased production of cane in other countries which has caused a considerable fall in prices. Then, again, the Peruvian producers have had to contend with scarcity of labour, limited water supplies, a long and protracted foreign war, which brought about a most serious financial crisis, the effects of which are felt even to day.

Notwithstanding these drawbacks, the sugar industry is still one of the most important in the country, and one which promises to increase if proper attention is paid it. As a proof of this, I may mention that the production, during 1891, has reached 67,000 tons, an increase of about 10,000 tons over the preceding year. Some of the estates are provided with every modern appliance, such as narrow-gauge railways for the carriage of the cane from the fields to the sugar-houses. During the last year an English company has bought over one of the estates in the Chicama Valley, and put up powerful machinery of the most modern description, of the well-known firm of Fawcett, Preston and Co. The sugar-houses and the different departments have been fitted up with electric light, so that work is now going on at full pressure day and night. Due to the impulse which the capital invested has given to this estate, there is every reason to believe that this year's output of sugar alone will exceed 6,000 tons. The success which this venture has obtained, I understand, has been the cause of some inquiry after the Peruvian sugar estates, and I should not be at all surprised to learn that several others are being bought over by English companies.

Another instance where the purchase of a going concern in Peru has proved profitable to investors, is the case of Messrs. Backus and Johnston's brewery in Lima. These gentlemen established, in 1880, a very large brewery in Lima in order to meet the ever increasing demand for a light laager-beer. In 1890 their concern, which was, at the time, a most prosperous business, was bought over by an English company, and as a result of the capital invested in the business, I may mention that to-day the production has been quadrupled, and that the supply quite equals the demand.

The foregoing will convey to you what can be done in such a country as Peru when capital is forthcoming.

Like these, there are other industries which might be taken up and developed, and also others, entirely new to the country, which might be introduced at a great profit to the investors.

In the mining industries Peru has likewise had to depend upon native capital, and although we can boast of several big fortunes made in the mines, and within the last twenty years, I must confess that, in a great measure, this industry has not returned to its former prosperity, due to the scarcity of available capital in the country for the proper development of such an expensive and speculative industry.

Within the last few years some English companies have taken over Peruvian mines, and I have not heard of the investors having had any reason for complaint.

Speaking of the mining industries, I may mention the concentrating and smelting works at Casapalca, in the rich mining district of Huarochiri. These works date since 1889, and their products consist of base bullion and copper *matte*.

The plant is most perfect, and consists of Freue-Venner concentrators, stamps, crushing mills, reverberatory furnaces, Bruckner furnaces, kilns, a 40-ton water-jacket furnace, a complete laboratory is attached to the establishment, and in every respect the work ranks among the first of its class in South America. Sixty tons of ore can be treated daily at the works.

In the other mining districts I think that establishments of this class would be paying concerns, and although there are other smelting and concentrating works in Peru, yet none are so perfect as those at Casapalca.

One of the drawbacks in Peru to all industries has been the excessive price of fuel. English and Australian coal costs about £3 a ton in Lima, while the price for Chilian and native coal varies between 30s. and 40s. the ton. But as I said before, that Peru might really be considered as nature's most favoured country, the discovery of vast petroleum fields in different parts of the country, and the application of the crude oil as fuel in lieu of coal, has completely altered such a state of affairs.

The existence of bitumen, pitch, and petroleum in Peru was proved many years ago, but as always happens in the case of rich countries, while Peru had guano and nitrate to live upon, nobody worried himself about gold, silver, or oil. To-day, things have changed, and so it is that everyone now looks for the natural and true sources of wealth, such as agriculture and the many known rich mines which exist all over the immense territory. Following on this it was only natural that the petroleum district of Peru should have been surveyed, and the result has been to prove that Peru, in the Department of Piura, alone possesses over 16,000 square miles of petroliferous soil. Such a discovery at a moment when coal keeps rising in price, and when petroleum is in greater and increasing demand, and is considered on all sides to be the destined fuel of the future, brought about something like a fever in the country, and a rush was made for the petroleum fields. In 1888, there were 23 claims registered; in 1889, 36; and in 1890, 97; and last year the number had risen to 613.

Since these discoveries, two English companies and two syndicates have already been formed in order to buy some of these properties. So at present these fields are being worked to some extent. The result has been that Peru will shortly consume entirely her own product, and that she will be in a condition to supply the whole South American markets as well as China and Australasia.

The pioneer works in Peru belong to an Italian gentleman, Signor Piaggio, who has at Zorritos 54 claims of 40,000 square metres each. At present 11 wells are being worked, and these supply sufficient oil for refining 6,000 cases per month. These works have fine machinery, and the property is well equipped and fitted up in every respect.

Of the English companies, the London and Pacific Petroleum Company, Limited, is for the present the one which has the first and largest establishment for refining petroleum and supplying oil fuel in the country. The company possesses some tank steamers, and has just started an experiment of introducing Peruvian kerosene into China, a venture which I hope may meet with every success. The following figures will give an idea of the progress which this industry is already making at Zorritos:—

EXPORTS.

	kilos.
(1889.)	
Crude oil	2,151,874
Kerosene	999,658
Lubricating clear oil	457,799
(1890.)	
Crude oil	2,324,219
Kerosene	1,199,161
Lubricating clear oil	1,115,677

and from Talara, where the London and Pacific Petroleum Company are established, the exports during 1890 consisted of 1,100 tons of crude oil in tanks, 46,589 cases of kerosene, and 4,000 barrels of lubricating fine oil.

The future of mineral oil, as a fuel, has advanced another step, perhaps its final one, since the recent important invention of Mr. Chenhall for solidifying the crude oil. If, as appears from the tests and experiments to which the petroleum in its new form has been subjected by some of your most trustworthy and experienced engineers and chemical analysts, the problem of solidification has been solved, then indeed must Peru be congratulated on her extraordinary good luck, which will give the country a most valuable industry, one which I may describe as the parent industry to nearly all others. With fuel of a superior quality, advantageously situated for exportation, capital will not then tarry to come to the country, and give impulse and life to new and and at present latent industries. What strides in the way of progress a country thus favoured will be able to make, I leave to you to consider.

I must now bring my reading to an end, leaving many and important subjects for other and better hands than mine. But, before I sit down, I beg to call your attention to one point, which I am sure will interest you, even if commerce and industrial enterprise be not among the pursuits or callings of all. I refer to the action of the Government of the United

States of America, in promoting the establishment of a Bureau of Information of the Latin-American Republics at Washington; and, I ask, why could not a similar thing be attempted here in this great metropolis, where, undoubtedly, the commercial, industrial, and financial interests of those countries are rooted, and from whence the capital, which gives life and vigour to every enterprise, emanates?

Some time ago a friend of mine, Mr. L. Tamini, an Argentine gentleman, communicated to me a plan for establishing in the great city of London a Latin-American Chamber of Commerce and Bureau of Information. I endorsed his views; and, with the help of Messrs. Baille, Consul for Paraguay, and Mr. Mackinnon, Consul for Uruguay, we tried to give form to this splendid idea. The financial crisis of 1890, and the political and economical outlook in some of the most important sections of the South American continent, spoiled our labours, which, perhaps, did not meet with all the encouragement which they deserved from the public supposed to be interested in Latin-American affairs; this, I believe, in sympathy to the abnormal situation which the city experienced at the time. However, be the reason and cause what it may, the fact is that we have not been able to carry out our idea on the lines proposed, and therefore have had to content ourselves—at least, for the time being—with an embryo Chamber of Commerce. This exists, perhaps, more in our imagination than in reality, but it nevertheless exists, and I think that, by a little propping here and raising there, it might be made the very bureau which I consider most important should exist in such a centre as London.

The average Latin-American, who comes to this country on business, finds himself lost in London, as he ignores the language, and, above all, the special manner in which English business and transactions are conducted. If he does not fall into the clutches of men of straw he may consider himself very lucky, but the chances are ten to one that, wishing to avoid them, he gets caught in their meshes at some boarding-house where he is probably staying, in order to learn or practice, as the case may be, English. The result is that his business is hawked about, and as the person in charge of it is of very dubious standing, to put it mildly, it is naturally rejected, without the honours of a listening or of a reading. Meanwhile the confiding, but ignorant, would-be vendor is whiling away his time sight-seeing, and speculating on, when not actually living upon, his future gains. The months pass, and at last he is told that the times are bad; that money is tight or loose; that the state of his or of the neighbouring country is troubled; that the smash of such a firm in Honolulu, or any other place on the earth, has produced a financial crisis, and that there is no prospect whatever of doing business for the moment. After having spent more money than was necessary, the individual returns home to tell his friends and countrymen that there is no business possible in England; and thus, perhaps, a good concession or a good business is thrown over or buried in oblivion until another chance is given it.

The Bureau which I recommend, would be the rendezvous for all Latin-Americans in this city; thither they would go to discuss business and to meet the persons they should have made appointments with. As for the English portion of the public, they would be able to obtain from such a bureau all the information they should require without having to call upon the consuls at all hours, and get, perhaps, about one-tenth of what they expected.

That the proper organisation of such a chamber or bureau is useful, need not be pointed out to you, as it is to-day a universally acknowledged fact that it is through such institutions, and by their aid, that the spreading of commerce from nation to nation is carried on.

I must now apologise to you all for my very dry discourse, which I thank you for having listened so attentively to. I hope that I have impressed you with the importance of the country which I have so poorly and confusedly attempted to describe to you, and that it and you may derive some positive benefit from what has been put forward.

DISCUSSION.

The CHAIRMAN thought that the exhaustive paper to which they had just listened must have conveyed to them a great deal of information about Peru, a country in which Englishmen ought to be deeply interested, as England had a greater amount of trade and commerce with Peru than with any other country in the world. The paper embraced a number of subjects, such as the question of immigration, public works, including railways, products of the country, manufactures, and the navigation of the Amazon, as well as financial questions; and no doubt there were many present who would be glad to speak upon one or the other of these subjects. He hoped that some remarks would be forthcoming as to the formation of the Bureau of Information, to which reference had been made in the paper.

Sir ALFRED DENT thought the facts collected by Señor Pezet must carry a great deal of weight, seeing the important position he occupied in England as Consul-General for Peru. So long as Señor Pezet held that office, he felt confident that his country would be well served, and that those who came in contact with him would be well pleased. Amongst other subjects alluded to, was the interest which Englishmen had in Peru. That was perhaps more centralised now that a great company had been started in London, whose special business it was to work and develop all the railways and other properties which Peru had handed over to the bondholders, and to bring that enterprise into a good commercial position which would do credit to the Englishmen who undertook the work, and bring that success to Peru which the country so much needed. The railways were peculiarly interesting to those who had time to study them, seeing that many hundred thousands of pounds sterling had been spent upon them. The Southern Railway crossed the Andes at a great elevation, when it went down to Lake Titicaca, which was some 13,000 feet above the level of the sea, 150 miles long and 40 miles wide in many parts. The lake was navigated by two small steamers, and a third steamer of much larger capacity, which had recently been built upon the Clyde, would shortly be added. This steamer, which is 170 feet long, will shortly be shipped to Mollendo, and having been taken over the Andes and through the tunnels, would be put together on the border of the lake at Puno. It is proposed, by means of this steamer, to navigate the lake to the mouth of the river Desaquedero at the further end, in order to open up the mineral districts; and in time the southern railway would probably be extended from that point to La Paz, the capital of Bolivia, thus increasing the lake traffic. The Central Railway, further north, commences at Callao and Lima, crosses the Cordilleras at an elevation much higher than Mont Blanc. It afterwards dives down in the direction of the tributaries of the Amazon into a most fertile agricultural country, and it is the forests of this country that the well-known Ceylon planters, Mr. Ross, Mr. Sinclair, and Mr. Clarke, have been exploring lately on behalf of the Peruvian Corporation. They all give a glowing description of the soil and district from a planter's point of view; and it is hoped that several planting industries will soon be started there under the management of Ceylon men. The two difficulties to be dealt with are that of labour and transport, though the latter would be overcome no doubt as soon as the railways were extended. With regard to the labour, they were told that there were a good many natives in the interior of Peru, but it was a question how far that labour was available to meet the wishes and wants of English planters. They hoped to introduce foreign labour—Chinese and others—and they looked to the Peruvian authorities to do all they could to assist them in this direction. The Chinese were a very industrious class, and if properly treated, proved to be the best labourers in the world for the tropical regions. As regarded petroleum, which was being extracted by one or two companies, he might say that petroleum was being largely used in the form of liquid fuel on the railways, nearly all the locomotives having been converted so that they could burn refuse petroleum, thus effecting a saving of some 40 or 50 per cent. They had been told that English coal cost £3 a ton in Lima, but he was glad to say they could get it for considerably less than that now, though in many of the mining districts the miners would willingly pay £12 a ton for coal. Speaking from an agricultural point of view, from all accounts to hand it was clear that the soil was of a very rich kind, and the climate also was most enviable. At Lima the temperature was from 60° to 80°, which was the most perfect climate to live in. Fevers were comparatively unknown there. Peru had one advantage over many of the South American States, viz., that its paper currency had practically disappeared, wages and the like being paid in coin (Peruvian dollars). Señor Pezet had rather led the meeting to believe that the question of solidifying petroleum had been solved, but perhaps the Society of Arts would have a word to say upon that question later on, as many seemed to doubt whether this question had been absolutely settled. No doubt if the refuse petroleum could be solidified, when it might be easily carried, and afterwards liquified so as to be used on board ship, it would do a great deal towards supplanting coal. He was strongly in favour of the establishment of a Bureau in this country at which information could be obtained by those who wished to seek their fortunes in South American colonies. The first qualification necessary for that was a knowledge of the Spanish language. It had been the fashion, of late years, to learn German, though he could not quite see the use of this language to a man who had to make his way in the world. It might be useful for academic purposes, but it was not nearly as useful a language as Spanish in the Colonies of the New World. Of course, this was a subject upon which opinions might differ.

Colonel HARRIS said, as an old resident in Peru for twenty years, and one who had known Señor Pezet from a child, he could not refrain from making a few remarks upon the excellent paper which had been read. He could endorse nearly the whole of it, having travelled from north to south and east to west in Peru. He concurred in the statement as to the natural riches of the nation. It was almost like a fairy tale; but Señor Pezet had only touched the fringe of the natural sources of Peru. Time would prove, as railways were opened and immigration was poured into the country, that all he had stated was correct. As one of the pioneers of the mining industry, he did not think that enough had been said of the wonderful gold sources of Peru. In Caraybaya

and Sandia, which were only four days' journey from a railway, the country teemed with gold, both in the alluvial and in mines; and it was snrprising that English capitalists should go thousands of miles to the wilds of Africa, when they could go comfortably in a steamer to Mollendo, and thus get within four days' journey of one of the richest deposits of gold in the world. The finest coffee was also grown in Peru; in fact, the quality was so much appreciated that very little of it was ever sent away. His son, who had a large interest in the northern part of Peru, was at the present moment sinking wells for petroleum. One of the companies there had a 4-inch hole from which a spout of oil rose 25 feet above the surface. This would give some idea of the quantity of oil there. He did not believe that the supply would ever be exhausted. Many experts thought that the deposit of oil was far greater and much superior to that of Pennsylvania or Baku. He disagreed with Señor Pezet entirely on the question of solidifying petroleum. This had been tried in Russia by means of a soap, which turned the petroleum into a kind of vaseline. The cost of doing this was from £1 to 25s. a ton, which, in itself, was quite sufficient to prevent the process from being carried out successfully. There would always be an immense demand for petroleum on the coast. At the present moment the Pacific Steam Navigation Company were using 100,000 tons of coal per year, but if they could use petroleum, and take in a cargo within two or three hours at their very door, an enormous saving would be effected. He thought the time was not far distant when a large number of steamers would be supplied with petroleum fuel from this district.

Mr. G. E. CHURCH said he might safely endorse all that Señor Pezet had said with regard to the vast resources of Peru. He was one of those who believed that Peru had now commenced its true era of national development, and his reasons for so thinking were these. From the time of the conquest, from 1525, up to the war of independence, Peru was under the rule of the viceroys. Everyone knew what that was, it was a rule of ruin and of the absolute depopulation of the country. The Spaniards built no roads; and the only two good buildings that they ever built were the cathedral and the mint. These they never repaired. Under Spanish rule, the Peruvians remained an illiterate race. After some years the Peruvians drove out the Spaniards, and then came the question what form of government should they adopt? The wildest republican theories were adopted, born of the teachings of the French Revolution; and, for 40 years, they cut each other's throats, until, finally, they acquired some stability. Then came a period when Europe wanted Peruvian guano—a period of prodigality and plunder. The natives did not develop the mining and agricultural wealth of the country; but everybody seemed to be related to everybody else who had an office under the Government, and so long as the guano lasted the period of prodigality and plunder went on riotously. Upon the guano becoming exhausted, nitrate took its place; but this having attracted the attention of Chili, the result was, that a war broke out in 1879—never mind under what pretext, though he fancied everyone knew that it was the nitrate fields. The reader of the paper spoke of this war as a misfortune to Peru, but he should characterise it as the turning point of her fortunes. It was the greatest blessing that could possibly have happened to her, as it made everybody poor, and they could not live any longer on the Government. When Chili had taken the nitrate fields, and left Peru stripped of everything, they were about as reduced as any nation could possibly be. They had to commence to wear out their old clothes, as they had nothing to exchange for new ones. This period continued for about six or eight years, from 1882 to 1889. Slowly coming to their senses, they began to comprehend that the real wealth of the country consisted in mining and agriculture. It was for this reason that he contended Peru had commenced her regeneration by going to work to develop her vast mineral and agricultural resources. But then came the crucial point, how were they going to do this on a grand scale without increased population? They had very profitably turned over the railways to the Peruvian Corporation, which would contribute very largely to the regeneration that everyone desired. That brought him to the question of immigration. Immigrants were strange people; the immigrant who was good for one country might be very inferior for another. You had to take the native population into consideration. In Peru the mountain people did not like to go to the lowlands, and the lowland people did not like to go to the mountains. They did not thrive by the change. You had to seek a class of immigration for Peru having regard to the considerations of the place where you could put them, and the products of the district to be cultivated. The reader of the paper had spoken of the lazy nigger, but negroes were a great deal like white men, they would not work unless obliged to. They were very similar to other races in this respect; it depended a great deal on how you treated them. Numberless laws might be made, but this would not get immigrants. If you got one immigrant you would not get two, unless the first wrote back, and said he liked the country and the way he was treated. The great fault with Peru was that the immigrant was badgered about by all the little petty authorities, the result being that life was made miserable to him; and he would write back to his friends, and say, "Don't come here." He told the Prime Minister, when asked, a few years ago, at Rio de Janeiro, as to why immigration could not be got in Brazil, that it was because of the bad way the immigrants were treated, they being then classed the same, socially, as slaves. Until

labour was respected, and considered honourable, they would never get immigration. He hoped he would be excused for being perfectly frank about this subject. He was a great admirer and had firm faith in the future of Peru, believing that it had got through its babyhood, and would become a grand country.

Mr. A. Ross said, as one of the Commissioners who had been sent out by the Peruvian Corporation to examine the agricultural resources of the country, he might say that he thought the reader of the paper had rather underestimated the riches of the country, both mineral and agricultural. What was required to open out the country was the introduction of labour from other places. The climate of Lima, at the time of our arrival in Peru, in June last year, was very much the same as that of London during summer, with the exception that it seldom rained. By means of irrigation the coast could be turned into a vast sugar plantation. In fact all along the central part of Peru it was suitable for European immigration. The railways were being rapidly extended in the interior, and shortly an interoceanic communication would be open from the Atlantic through the Amazon and overland to the Pacific.

Mr. J. Ferguson (Ceylon) said interest in Peru was not confined to England. Those living in the east of India and Ceylon had a special interest in Peru, because of one of the greatest blessings that had been conferred upon the human race in Southern Asia, viz., the introduction of the cinchona plant. A few plants were brought to Bombay, in 1861, by Mr. Markham, and the cultivation was commenced by Government on the Nilgiris and in the Hakgala-gardens, Ceylon, the result being that the cultivation of that product in the eastern world had increased to such an extent that the price of quinine, which at that time was 16s. an ounce, had now been reduced to 9d. an ounce. What that meant to the lives of millions in India and China, the European world had but little conception. When coffee failed in Ceylon, their planters went in for cinchona, and for some years this was a profitable investment, until the exports reached nearly 16,000,000 lbs. of bark in 1887, and since then the price tumbled down so enormously that the ordinary cinchona trees remaining in Ceylon became not much more valuable than the weeds on a plantation. Our planters had next to take to tea. But there was some danger that tea in India and Ceylon might follow very much in the wake of cinchona through over-production in proportion to demand. In ten years the exports from Ceylon alone had risen from almost nothing to 68,000,000 lb., and there was the prospect ere long of their reaching 100,000,000 lb. annually. Now, while warning them against tea, on the other hand he would remind intending planters in Peru that coffee had failed in India, Ceylon, and Java. The eastern world now did not give one-fourth the quantity of coffee it did a few years ago, and Ceylon planters in Brazil represented that it had got to the top of the tide with regard to coffee. Therefore what they had heard that evening of coffee doing so well in Peru as well as cacao, gave the greatest possible encouragement to capitalists and planters to look to Eastern Peru as a future place of supply for these valuable products. He said this because he had had the pleasure of reading Mr. Clark's report, as well as the unpublished report by Messrs. Ross and Sinclair. The opinion of these latter two practical coffee and cacao planters would be accepted in the eastern planting world, when their report appeared, as about the best opinions the Peruvian Corporation could possibly have with regard to tropical products in Peru. Ceylon continued to be the best school in the world for the training of tropical agriculturists, and the Ceylon planters would read of the prospect in Peru with the greatest possible interest, and as the hill country of their little island might be getting rather overcrowded, some of their planters would no doubt begin to turn their attention to the west, and perhaps, ere long, make their way to the Amazonian regions of Peru.

Mr. J. I. Watts said, having visited and taken a great interest in Peru, he could endorse all that Mr. Pezet had said with regard to agriculture. The picture had not been overdrawn in the slightest. The cows raised upon the farms in Peru would not disgrace any agricultural show; their yield of milk being also large and of the richest quality. The results obtained in this direction were no doubt largely due to the richness of the pastures, and to the splendid climate. He could not say so much for the sheep, although he had seen some very fine specimens there. In 1876, he crossed Peruvian rams with Dorset sheep, the result of which had far exceeded his expectations, and the breed of sheep was now being considerably improved. He considered there was a very great future for Peru, both from its vast agricultural and its mineral resources.

The Chairman, in proposing a vote of thanks to the reader of the paper, said he thought there was a peculiar fitness in their having received this information from Señor Pezet; there was an official fitness, and there was an hereditary fitness. Señor Pezet's great grandfather was one of the very first men in Peru who raised the cry of freedom, and he was a martyr to that noble cause. Señor Pezet's grandfather, whose acquaintance he had the pleasure of making in years now long gone by, was one of the most accomplished Presidents of Peru, and the one who introduced the decimal system into that country. Señor Pezet himself had served his country in war, and had done good service in peace; in fact, he was doing most excellent service to his country at the present time

in England in his official capacity as Consul-General. For these reasons he had great pleasure in congratulating the meeting upon the valuable paper which had been read; and he might also congratulate Señor Pezet on the interesting discussion which had taken place. He begged to propose a cordial vote of thanks to the author of the paper.

The vote of thanks having been carried,

Mr. PEZET, in returning thanks, said if he had touched upon all the points which had been referred to in the discussion, the paper would have been double the length it was. If any one required further information upon any subject he should be happy at any time to give it. He believed that Peru had now turned over a new leaf. Though he could not quite accept everything which Mr. Church had said, at the same time he accepted the general points.

FIFTEENTH ORDINARY MEETING.

Wednesday, March 23, 1892; Sir FREDERICK J. BRAMWELL, Bart., D.C.L., F.R.S. (Deputy-Chairman of the Council), in the chair.

The following candidates were proposed for election as members of the Society:—

Kirby, Frederick Hall, Union Club, Trafalgar-square, W.C.
Meachan, Charles S., Brewery-house, Earl-street, Maidstone, Kent.

The following candidates were balloted for and duly elected members of the Society:—

Chase, George B., 234, Beacon-street, Boston, Mass., U.S.A.
Formoy, James Arthur, Lestelle, Forest-hill, S.E.
Goodridge, Captain John James Lewis, Portswood, Southampton, Hampshire.
Mallet, Robert Trefusis, 1, Philbeach-gardens, South Kensington, S.W.
Wye, Thomas Henry, Brooklands, Leytonstone, Essex.

The paper read was—

THE MANUFACTURE AND INDUSTRIAL APPLICATIONS OF FLEXIBLE TUBING.

By GILBERT R. REDGRAVE, Assoc.Inst.C.E.

The history of the extensive use of flexible tubing seems to be most closely related to that of india-rubber, which substance, in its various forms, has furnished the principal descriptions of flexible tubing at present in the market. Previous to the discovery of caoutchouc, the name by which the raw rubber was at first known, and which was the South American Indian word, denoting the india-rubber tree—the *Siphonia elastica*—the different kinds of flexible tubing seem to have been prepared either from strips of leather fastened together by means of copper or metal rivets, or by winding thin bands of linen or other fabrics, soaked in gums or varnishes, round a mandrel or core. The use of tubes or hose, woven in a circular form without a seam, is an invention of much later date, and would appear to belong to T. B. Brown, who patented a seamless hose in 1849, though he seems to have been anticipated by Hegner as long ago as 1792.

The commercial employment of india-rubber —the inspissated or coagulated juice of several varieties of trees—dates back to the early years of the present century, but it scarcely attained to any real importance until Hancock's spreading process, which was made known in 1837, or the perhaps even more important invention of the process of vulcanising rubber, or causing it to combine with a certain percentage of sulphur, which was patented by Hancock in 1843. Another epoch-making event in the history of this material was the plan of cold curing, which involves the use of carbon bisulphide, discovered by Parkes, in 1846. It is scarcely necessary that I should trouble you now with the history of india-rubber manufacture, for this matter has been dealt with on previous occasions in this room, and the various processes were fully described by Mr. Bolas, in a series of Cantor lectures, in 1880. I may, however, very briefly allude to that branch of the manufacture connected with the production of tubing of this material.

India-rubber tubing is manufactured by two distinct methods:—

1. By squeezing or squirting the prepared semi-fluid rubber through a die or orifice; and

2. By the mechanical jointing of hollow cylinders of sheet rubber.

In a machine, invented by Mr. Francis Shaw, all the requisite ingredients are conveyed, by means of a hopper, into a horizontal cylinder, kept at the requisite temperature by a steam-jacket. In the interior of this cylinder the rubber is compressed by the action of a piston or plunger, and is forced out at the end through a die or nozzle of any required section. The tube, as it emerges, is coated with powdered steatite, and is packed in a layer of this material, in order that it may be

vulcanised, by means of dry heat, in a vulcanising chamber. It is then ready for the market.

In the second process, india-rubber is spread upon sized cloth, and stripped into sheets. It is then cut into strips of the right width, to furnish a tube of the requisite diameter, when bent round into a cylindrical form. Next, the cut edges are bevelled, which causes the surfaces to unite more perfectly when brought into contact with each other. The strips are then passed through a heated die, being previously doubled into the form of a cylinder. In their passage through the die—which is of the requisite size to form the tubing—the bevelled edges are compressed together and made to unite. In this way a tube is produced, which, as it issues, is coated, as before described, with steatite powder, and subsequently vulcanised.

The red-coloured rubber tubing, which is considered by some to be more durable than the grey, is made by employing orange-red coloured antimony pentasulphide with the "mixing"—the technical name for the prepared ingredients—and the superior strength of this rubber does not in any way depend upon the colouring matter, but must be due to better quality in the mixing.

The production of a flexible tube or pipe of metal has long been a desideratum, and the subject has not escaped the thoughtful attention of inventors, as a brief scrutiny of the records of the Patent-office will not fail to show. I cannot hope on the present occasion to bring under your notice a tithe of these inventions. I may, however, point out that a favourite plan of overcoming the difficulty involves the use of coiled wire, either alone in several thicknesses or in conjunction with a metal strip of some other section. I have some specimens here of some of these varieties of tubing; thus under an ingenious plan of American origin, tubing is produced by the combination of a wire and a triangular fillet. It will be readily understood that a tube constructed in this way on the helical principle would be possessed of considerable strength, though I should be inclined to doubt its tightness, owing to the small extent of metallic surface in contact, while the relative weight of metal required per foot of tube is more than treble that of the invention I shall hereafter describe.

Another method of building up a flexible tube is on what has been termed the accordion system, wherein numerous thin concave discs of metal are soldered together alternately, at their inner and outer edges. This really constitutes a series of rings, or a tube is produced on what is termed the annular system. Such a tube is a very flexible, but not a very strong one, and this cannot fail to be of course a relatively expensive plan of obtaining the object in view. Flexible tubes have also been produced from super-imposed coils of channel and half-round sections of corrugated metal, having a packing of india-rubber at their junctions. The section of this kind of tubing is very similar to that first employed in the invention of Mons. Levavasseur. By binding india-rubber tubing externally with a spiral coil of wire, and introducing within the rubber tube a lining of coiled wire, the different kinds of so-called "sphincter-grip armoured hose" are produced.

A moment's consideration of the difficulties involved in the manufacture of a flexible metallic tube will serve to indicate not only the direction in which the question has to be approached, but also the readiest method by which the task may be accomplished. It is clear that to obtain flexion the tube must be built up of a vast number of small moving parts, and that the degree of flexibility will, to a great extent, depend upon the relative size of these parts. If we contrive a joint, which permits of a certain amount of play, and this joint occurs at certain fixed intervals, the total extent of flexibility in a given length of tubing will be contingent upon the extreme amount of play at each joint, multiplied by the number of joints in such given length, assuming always, as we are bound to do in the case of a tube of metal, that the sections themselves are rigid. The movement or play must, therefore, in the case of a tube of metal, be provided at the joint. Now, a very brief study of the problem will further teach us that such a tube may best be formed from a continuous strip of metal spirally wound, as it would be impossible, or next to impossible, on the score of cost, to contrive a series of rings, securely jointed one within the other on the annular system, with movable joints, each of such rings being sufficiently narrow to ensure the due degree of flexibility in the tube.

For many purposes, it is true, where a very slight amount of flexibility is required, the provision for such play is secured by joints of the above-mentioned kind. Thus, for earthenware or stoneware pipes, which, as you are aware, have to be laid in trenches, and which, even with the utmost care in the laying, are liable to slight movements by settlement or displacement, a joint, known

after its inventor, Mr. Stanford, has been devised, in which the spigot end of the one pipe has a ring of pitch or composition, which fits into a faucet in the adjoining pipe similarly prepared. As will be evident, from the form of this joint, a small amount of displacement would not be fatal to it, while a rigid joint, formed of cement, or similar material, would be crushed by a very slight settlement. For the junction of metal pipes, which are laid in much longer sections, gene- of 9 or 12 feet in length, a very ingenious joint has been devised, which depends upon the elasticity of a ring of vulcanised india-rubber, resting in a groove on the spigot of the pipe, and rolling into the faucet, when the two pipes are forced together to make the joint. The tightness of this joint depends of course upon the soundness of the rubber; and, as I shall show that rubber used in this way is liable to deterioration and decay, we are bound to assume that this is not a joint of a permanently durable character.

All engineers are aware that it is no easy matter to produce an absolutely tight joint between two metal surfaces; and for this reason alone most of the earlier efforts to obtain a flexible metal tube were based on the use of some foreign substance to form a packing. This substance was generally a strip of india-rubber, and, for the reasons already given, the first flexible metal tubes could not be regarded as otherwise than imperfect from the point of view of durability.

As I have already pointed out, the problem of making a flexible tube of metal was found to depend upon the method of coiling a strip of metal in a spiral form round a mandrel or core in such a way that the continuous joint or seam between each coil of the helix was not only perfectly sound, but was also possessed of mobility. In tracing out the gradual steps by which this problem has been mastered, I shall have to bring before you the history of the so-called flexible metallic tubing, the invention of Mons. E. Levavasseur.

M. Levavasseur has given me the following brief account of the details of his discovery. Some twenty years ago, while engaged in the manufacture of jewellery, he produced bracelets and necklaces of thin laminæ of gold and silver, the original form of which was tubular; the tube being built up of strips of metal of two different sections, coiled one above the other. To accomplish this a flat channelled section is first employed, above which is wound a semicircular clip, serving to unite the channels together, and to form a complete tube. This pattern, either circular in section or flattened into an oval form by hydraulic pressure, was, for many years, in great request for necklaces of gold and silver, and M. Levavasseur was profitably employed in their manufacture under the terms of a patent which he had obtained for the invention. In time, he was able to produce necklets and other ornaments from coiled metal strips on the inter-locking principle, having an S section, where only one continuous strip is used, and the convolutions grip one into the other. While he was engaged in the manufacture of jewellery, he designed nearly all the different forms of corrugation now used for tubing.

It was not until about six years ago, when he was walking one day with his partner in a Paris thoroughfare, that the invention, in its present shape, took practical form. He saw the men engaged in cleansing the asphalte with that curious apparatus which is so frequently seen in Paris, but which I do not remember to have met with elsewhere, viz., short lengths of piping, carried on a pair of small wheels fore and aft, and joined together by copper-rivetted leather hose, to secure flexibility. M. Levavasseur remarked to his partner that this seemed a very unwieldy and cumbrous contrivance, unworthy of the 19th century, and he was surprised that something different was not introduced. His partner said that they used it in default of some better substitute, which had still to be provided. Said M. Levavasseur, "I could contrive something much better adapted for the purpose, and far lighter and more flexible." On being asked to explain, he said, "I should make an enlarged tube of the same kind as we use for the spiral necklaces, and insert a strip of india-rubber between each coil to make it water-tight." His partner saw at once the value of the notion, and it was forthwith patented, and has now been developed into the tubing I am able to bring under your notice this evening.

Starting with a simple ribbon of metal, which we will, in the first case, regard as perfectly flat, but capable of being coiled in a spiral form round a core, we should obtain a tube; but in order to obtain a cylindrical tube, we must assume the metal to undergo a certain amount of distortion, for the tendency of such a strip would be to take the form of a truncated cone. This fact may be familiarly illustrated by a strip of paper wound in the required manner to

form a spill, which, it is well known, tapers from the base upwards. A tube thus wound would obtain its flexibility by the sliding of one coil over the other; but the flexibility, in this case, would be very trifling, the coils would very readily be strained apart, and would be very liable to become clogged with grit and dirt. As a matter of fact, it would be quite impossible to produce in this manner, even with a strip of india-rubber inserted along the seam, a sound and tight flexible tube.

Starting then with the plain strip, it appears that means must be devised to form something superior to the simple lap-joint we have just investigated. The strip must, in fact, be corrugated, and in the first form of the invention the strip was corrugated by a similar process to that by which iron bars of various sections are drawn out in the rolling-mill. In the strip originally employed, the section somewhat resembled the form of a double channel, and the strands or coils of metal were hooked together and grasped between them a small strip of rubber. The tightness of this joint clearly depends upon the presence of this rubber, and the play or flexibility is contingent upon the amount of movement possible of the one hook within the other. When the tube of this description is bent, the tendency will be for the joints along the outer-edge of the curve to draw closer together and to bite more firmly on to the rubber strip; but, on the other hand, for the corresponding parts of the joints on the inner face of the curve to open out and relinquish their grasp of the rubber. It will be apparent from the section, that in tubes exposed to much flexure there will be a great strain on the rubber, and it was found, in practice, that this joint, though it gave great flexibility, rapidly caused the rubber strip to work out and deteriorate. Not only, therefore, was this particular form of tube defective, in that it relied mainly for its soundness upon a perishable substance—the rubber—but it also exposed that rubber to an undue amount of wear and tear.

In the next stage of the invention we find strips of a fresh section employed, more resembling the figure of 8, and giving a much more perfect interlock between each coil. In tubes constructed of this section there is less flexibility, perhaps, than in those of the double channel type, but the rubber is much more securely embedded, and the tendency of the latter to work out is greatly reduced. Moreover, it becomes impossible for the coils to be drawn apart even under very great pressure, and the disruption of the tube can only be effected by a force sufficient to split the metal strip. Several types of this interlocking section, which were in turn introduced and tested, are shown in my diagrams. Where the rubber is so placed that it is gripped by the double hook, it becomes possible to cut the rubber to pieces by frequent and violent bending of the tube, but several of these sections seem to have overcome entirely the tendency, on the one hand, of the rubber strip to work out, and on the other, of the different coils of the metal to draw apart. The rubber strip, though it conveys an element of weakness, may, under certain circumstances, be employed with advantage. For instance, in flexible tubes, where the contents are at very low pressures, as in the case of gas tubing, the rubber may safely be introduced; but where the tubes have to be steam-tight, and where the contents of the tube are under great pressure, it is convenient to dispense altogether with the rubber strip. While I am dealing with this part of the subject, I may mention that, when rubber is used in an iron or steel tube, it remains practically unchanged for considerable periods of time, but that when it is employed in a tube of copper or brass, it appears to undergo some chemical action, which leads to its ultimate conversion into a dark resinous compound, devoid of elastic properties. This altered form of the india-rubber, though it serves as an admirable packing between the surfaces of metal, and certainly improves the tightness of the tubing, deprives it almost entirely of its flexibility.

Dr. Burghardt has pointed out that this deterioration is due to the action of oxygen, which is in reality the great enemy of all kinds of rubber. Certain of the heavy coal-tar oils, and many oils of animal and vegetable origin, such as tallow oil, fish oil, olive oil, and cotton-seed oil, when brought into contact with india-rubber seem to set up the oxidising process with fatal rapidity. Copper oxide, in conjunction with oil, is a source of peculiar danger to caoutchouc, and in the tubing formed of copper the destructive action has been observed in less than a twelvemonth. For those purposes, therefore, where the use of a rubber strip is advisable, it is necessary to employ a protective coating of tin or some other metal on the surface of the copper to guard against this action. Rubber, when fully oxidised, becomes quite brittle, and is split up into two resinous substances, the one discovered by Spiller is soluble in alcohol, ether,

and carbon bisulphide; the other substance, the discovery of Dr. Burghardt, is not acted upon by those solvents. Oil, which is usually freely employed in the manufacture of tubing, can, in order to obviate this danger, in the case of copper or brass, be replaced by soap and water, or some other lubricant, and an increased amount of rubber may be inserted in the space between the metal coils, to make good the waste.

An attempt to employ a flatter and less violent curve will be seen in the diagrams of certain of the sections, for it is manifest that the toughness of the metal must be severely tried during the process of rolling if the pattern to which it has to be rolled is one composed of a multiplicity of sharp angles. Further progress in the development of the invention shows a more complete interlocking of the metal strands, and slight modifications in the section. After many experiments, it was ascertained that none of these sections gave absolute security, and that the more completely was the interlocking principle carried out the greater was the sacrifice of the flexibility. Moreover, in these later varieties, where the india-rubber strip was closely gripped and compressed by the metal, it was proved that in time it deteriorated, or underwent some chemical or physical changes of the character to which I have already alluded.

Finding, after repeated trials, that it was impossible to produce satisfactory specimens of tubing in which the tightness of the joint was secured by means of a rubber strip, the next stage in the invention was the attempt to manufacture a spirally-wound tube in which this might be accomplished by simple interlocking of the coils of metal without packing of any kind. The well-known difficulty of producing a sound joint by metal against metal would appear at first sight to interpose almost insurmountable obstacles to success in this attempt, but after further experiments, a considerable measure of success was obtained. To roll a thin strip of flat metal into the section required it would be exposed to very severe strains, in consequence of the numerous sharp angles, and it is neccessary to effect the conversion by slow degrees by the use of a graduated series of molettes through which the metal passes many times. This particular section involves six almost right-angled bends, and the manufacture can only be carried out with a very ductile metal like the best soft iron, copper, or brass. The process of evolution, which resulted in the form of metal strip now employed, was a matter involving time and much consideration; and in the latest section, packing is entirely dispensed with. In its improved form, each metal strip has a comparatively large surface in contact with the one adjoining it, and, by the difference in the width of the two grooved channels, an ample allowance is made for play. This is, in fact, a piston joint, for the smaller corrugation works within the larger one, as the piston works within the cylinder. In the first form of this joint a notch was rolled upon the summit of the lesser corrugation to receive a thread of hemp, cotton, or asbestos, to serve as a species of packing; but in the present form of the coil, the packing has been entirely done away with, and we find nothing but the two metallic surfaces in contact.

It will appear, at first sight, to practical men who have had experience in metal work, that it would be absolutely impossible, under these conditions, to produce a continuous sound joint in a tube of any length, even under very moderate pressures; but that it should be possible to obtain by this means a steam-tight joint, or one capable of conveying petroleum oil gas at a pressure of 200 lbs. per square inch, will scarcely be credited. Such is, however, an undoubted fact, and the tube is not only perfectly tight under these conditions, but it likewise retains much of its flexibility. The only explanation is that in this form of joint the greater the internal pressure, the more firmly are the metal surfaces, which approximately form two sides of a square, brought into contact. There is no possibility of torsion, or what would be equivalent to a partial unwinding of the tube, because of the friction of the metallic surfaces; and as the internal pressure increases, in precisely the same ratio does the tightness or soundness of the tube increase, until the point is reached when the strain on the metal strip produces elongation or partial deformation of the section, and in the tube $\frac{3}{4}$ of an inch in diameter, formed of a coiled-strip 6-10th of a millimetre in thickness and 14 millimetres wide, this would appear to be reached at a pressure of about 2,000 lbs. per square inch. Not only is this tube tight at these very extreme pressures, but it is also capable of being used under the diminished internal pressure of a partial vacuum, a fact which is more difficult of scientific explanation than that of its capacity for resisting great internal pressure, for in this case a new set of factors come into play. Still it will be seen,

when the structure of the tube is investigated, that the external pressure, due to the atmosphere, will also tend to tighten the coils, when the air in the interior of the tubing is exhausted.

In tubing of this formation the degree of flexibility varies, of course, considerably, in proportion to the diameter and to the thickness of metal; but, it may be roughly stated, that a 5-16th inch tube may be formed into a circle 8 inches across, and an inch tube into a circle 12 inches in diameter.

If the principle on which the construction of the latest development of the tubing is based has been made clear to you, it will be evident that there is practically no limit to the size in which pipes of this kind might be produced; it only becomes a question of the mechanical power needed to roll the metal strips into sections, and to coil them into tubes. As this is at present effected by one continuous process in a single machine, it will be understood that the production of pipes of large diameter would need a very powerful plant; there are probably, however, but few uses for flexible tubes exceeding from 10 to 12 inches in diameter.

The mechanical difficulties which had to be overcome in the manufacture of the tube, in a single operation, were by no means inconsiderable. It may be sufficient, at the present time, to indicate a few of the more prominent of them; and, in the very first rank, I must mention the production of an extremely tough, and, at the same time, highly ductile metal ribbon, or strip, of absolute uniformity and very great length. For the tube, $\frac{3}{4}$-inch in diameter, a strip of metal, 6-10ths of a millimetre in thickness and 14 millimetres in width, is needed; and, at present, the limit of length for metal strips of this section appears to be about 6,000 to 7,000 feet. As it requires about ten feet of strip to produce one foot of inch tube, the utmost length of continuous piping of this calibre is at present limited, but I am given to understand that by the process of electrical welding it becomes possible to fuse together the metal strips so perfectly that any number of sections may be united to form a tube, practically unlimited in point of length.

Having secured a strip of suitable metal, the second process is to shape it to the various complicated sections shown in the diagrams on the wall. This shaping by means of molettes is an operation of great delicacy, and the production of the sharp bends, seen in the piston-joint section, needs very accurately adjusted pressure and very skilfully graduated molettes. The final process is that of coiling the corrugated strip in a spiral form round a core, thus forming the tube. In this operation the tension of the strip, the accurate adjustment of the metal surfaces, and the mode of release from the core, are the matters of chief moment. As already stated all these operations are now accomplished in a single machine which, from the plain strip, produces the tube complete and ready for use, in one continuous process.

It may be interesting, in connection with the subject of flexible tubing, to glance at some of its more prominent industrial applications. And here we may at once distinguish between two sets of conditions which come into play in this connection, namely, in the first instance, the flexibility alone, and, in the second, the capacity of the tube to withstand internal or external pressure. In the case of an ordinary india-rubber tube we find the first of these conditions most completely satisfied. A tube of this kind is capable of being very readily bent into any required form, and possesses most perfect pliability, but under the second set of conditions it takes a very low rank. If an india-rubber tube has to withstand pressure, even to a very moderate extent, it has to be greatly increased in thickness, and it becomes extremely rigid and cumbrous. Or it must be bound round with wire or strips of metal to keep its elasticity within bounds, which deprives it of its flexibility. Again, if it has to resist a partial vacuum, the rubber tube comes off badly, as it speedily collapses and suffers a great loss of calibre.

It is in both of these latter tests that the flexible metallic tubing takes such a high rank, and while it is capable, as has been seen, of resisting such extreme pressures as 2,700 lbs. per square inch, it can also be used under a vacuum approximate to that under which water is lifted, say 30 feet. When exposed to bursting pressure, the flexible tubing has been proved, as already stated, to remain watertight until a point very near the limit of strength of the metal ribbon of which it is composed. One great superiority of the flexible metal tubing over similar tubes of other material, is its power of supporting a heavy load placed upon it, either designedly or by accident. From experiments specially made for this paper it has been ascertained that the various sizes of tubing will support the undermentioned loads gradually placed on one square inch of bearing surface:—

Internal diameter of tube.	Weight in cwts. needed to compress tube to an oval section.	Weight in cwts. needed to crush tube.
5-16th inch	13	27
3-8th ,,	10	27
½ ,,	13	31
5-8th ,,	13	35
¾ ,,	18	42
1 ,,	18	49

A tube lying on the floor can thus be trodden upon with impunity, indeed a heavy cart might be driven over it on the road, and this feature alone is of the utmost importance when the question of the use of gas is considered. When gas is conveyed through a rubber tube, and the tube is stepped upon or otherwise compressed, the gas goes out, and an immediate escape of gas takes place. This is an undoubted element of danger in connection with the use of rubber tubing for the conveyance of gas, and the officers of insurance companies and others interested would do well to satisfy themselves of the important advantages in point of safety, possessed by the new tubing. The metallic tubing will also withstand, without injury, an increase of temperature which would entirely destroy tubes of india-rubber.

It is claimed for the flexible tubing, moreover, that it will not kink, and in its application to the diving-bell, this is a property that should secure its immediate introduction, for many fatal accidents have been ascribed to this defect in the tubing now employed. The comparatively trifling weight of the flexible tubing, as compared with its great strength, should lead to its adoption for many purposes in remote and distant countries where rigid metal tubing is now used, and it will undoubtedly form part of the equipment of the explorer in opening up new territories. For it must be remembered that it can be coiled away into a very small space, and that by the use of screw couplings the joints can very rapidly be made with unskilled labour. It does not require to be protected by placing it in trenches, and it is not attacked by white ants. This last fact is a point which has been strongly commended by those who have had experience of rubber tubing in hot climates.

Another matter, which is an important one, more especially in connection with the larger sizes of tubing, is the fact that expensive bends which need special patterns, take a long time to make, and require very careful and accurate fitting, are entirely dispensed with by the employment of this material, as it can readily be adjusted to the most complicated curves, and when once placed in position it retains its form unaltered.

For many purposes on board ship, where, owing to the constant motion and straining that takes place, all ordinary rigid tubing is found to be exposed to leakage and fracture, the flexible tubing can be utilised with perfect safety, as it will expand very considerably without any loss of tightness. It is probably owing to this fact that the new tubing is not liable to be damaged by frosts, and long-suffering householders who have annually to face heavy plumbers' bills, and the discomfort of a deluge of water, will hail an unbreakable pipe with acclamation.

In the course of the foregoing observations certain of the possible applications of the flexible metallic tubing have been noticed. I may now briefly enumerate some of the many purposes for which it has lately been employed. It is used to convey air under pressure for driving rock drills and boring machinery. It has been found perfectly steam-tight, and it was employed at the recent Royal Naval Exhibition to carry steam at pressures ranging up to 150 lbs. per square inch. It is, however, quite capable of resisting, under actual working conditions, even more severe tests than this, for a considerable quantity of the flexible tubing has been supplied to one of the leading railway companies to carry petroleum gas from the reservoirs to the carriages under a pressure of, in some cases, 200 lbs. per square inch. The tubing has also been applied with complete success to the pumping of petroleum oil, a liquid which has a peculiarly subtle power of penetrating joints of every description, and which furnishes a specially severe test for a flexible tube of this nature. In the manufacture of varnishes, in jam-making, in various brewery operations, for the suction pipes for publicans' beer-engines, for organ-blowing purposes, for carpet-beating machinery, and for speaking tubes, the new tubing has been used most successfully.

An extensive field of usefulness can be predicted for this invention when employed for covering insulated wires for telegraphic and telephoning purposes. I have here some specimens of small cables sheathed with the tubing. It would be quite impossible to drive a nail through a wire thus protected, and it would be

practically impossible to crush it or to injure it by friction in the ordinary way, which points to its use for the shore ends of cables. The cheapness of this mode of manufacturing the armoured wire would be greatly in its favour. The tubing has been proved to be most valuable in lighthouses for supplying the oil to the wicks, which, as is well known, are moved by automatic machinery, and need a permanent flexible connection with the oil vessels.

In all cases, where a certain amount of flexibility is needed, together with the property of retaining the form when bent, the new material will be found to possess just that degree of stiffness that is needed. It is quite possible to produce tubes having a greater or less degree of flexibility, according to the requirements of the user, as this property depends, to a great extent, upon the form of the corrugations and the thickness of the metal strips employed.

The tubing has been used for cooling purposes, to cover large shafts revolving at a high speed, and it might also be employed with advantage in the formation of worms for distilling and condensing apparatus. It has been applied to the hot calenders used for printing machines, and it has also been employed for gas irons for collar-dressing, &c.

In circumstances where a large temporary gas installation has to be rapidly carried out, or where workmen's benches have to be supplied with movable gas burners, as also in chemical laboratories for the Bunsen burners, the flexible tubing would be found most convenient. As already stated, it has been found to answer well as a suction pipe for hydraulic and pumping purposes.

Some few details respecting the weight of the tubing may be of interest. Thus, the tubing 5-16th inch in diameter, at present the smallest size made, weighs $2\frac{1}{2}$ oz. per lineal foot—

$\frac{3}{8}$-inch	tubing	weighs	3 oz.	per foot.
$\frac{1}{2}$	,,	,,	4	,,
$\frac{5}{8}$	,,	,,	$6\frac{1}{2}$	,,
$\frac{3}{4}$	,,	,,	$8\frac{1}{2}$	,,
1	,,	,,	11	,,
$1\frac{1}{4}$	,,	,,	15	,,
$1\frac{1}{2}$	,,	,,	17	,,

The two smaller sizes have been tested up to 2,700 lbs. per square inch of hydraulic pressure, the $\frac{1}{2}$-inch diameter tubing has withstood 2,000 lbs. per square inch; the larger sizes carry a gradually decreasing pressure down to 1,500 lbs. per square inch for the 1-inch tubing, but the bursting pressure depends somewhat on the gauges of the metal strips used in the manufacture of the tubing.

A matter of great importance in the practical employment of tubing is the possibility of forming a good and secure joint or coupling, and this has been very successfully effected by means of a simple screw connection. A conical cup is provided, into which the tubing is fastened by hemp, with white lead or with solder, in the usual way, and a double thread union, with screw nut, serves either to connect the tube, or to attach it to another length of tubing; in this latter case, a second cone-end is provided for the other tube. For gas tubes, a simple "push-on" connection may be employed with advantage. Where a strong joint for low pressures between two lengths of tubing of the same size is required, the simple collar joint, made in halves, and capable of being bolted together round the junction with a packing of india-rubber is all that is needed. It must be borne in mind that under no circumstances must tubing of this description be screwed, as this tends to destroy the helical structure and to expose it to leakage.

The price of this new tubing compares very favourably with that of similar tubes of rubber, and when its superior strength and durability are taken into consideration, any slight additional expense at the outset will soon be compensated for.

I have now brought under your notice some of the more important varieties of flexible tubing. It has been my endeavour to set forth the principles on which, in tubes of metal, this property is based, and to explain how success may best be ensured in the production of such tubes. In conclusion, a new invention has been described, which, I believe, will be found to satisfy the conditions that have been laid down. I hope to have succeeded in convincing you that in the flexible metallic tubing we possess a material having a very wide range of application, and a great field of usefulness in many of the leading branches of industry.

DISCUSSION.

Mr. F. Walton said he had been concerned with this tubing almost from the commencement, and, as had been shown, it had been a matter of evolution, the invention at first being rather crude, and requiring a great deal of time and money to develop it. They had now got a tube which was capable of answering a number

of purposes, though he would not say that it was absolutely perfect. They constantly had to meet different requirements, owing to the different conditions under which the tube had to work, some tubes remaining in a comparatively quiescent state, whilst others were in continuous movement. All these conditions had to be provided for by changes in the metal or in the form of corrugation; and many improvements had yet to be made.

Mr. J. IMRAY, having been employed in specifying some of the patents for this tubing, said he had had an opportunity of watching the progress of the invention, and seeing its gradual approach to the high pitch of excellence—almost of perfection—at which which it had now arrived. The very idea of making a tnbe of this kind appeared, at first sight, to involve an impossibility. To bend a strip of steel or other metal into six right-angled bends, and then coil it round a small mandrel, and yet keep it entire, one would have said was impossible, but yet it had been done. It was not done at first, however; it required a good many trials. The most remarkable thing about the tube was its air-tightness, which was produced by the mere contact of two surfaces of the same metal, which yet moved to and fro over one another. It had been suggested that the inside pressure kept one surface against the other, and so kept it tight, but that could hardly be the explanation, because there was quite as much pressure against the outer surface tending to push it away from the inner. Nor could it be the pressure outside, because it remained tight whether the pressure were great or small. After some consideration, he ventured to offer a suggestion, though he might be in error about it, and that was this. When the piece of steel, which might be con-
ered a girder, having two pockets on one side and
n the other, was bent round a mandrel, it was
er very great stress, the outer part being put
and the inner part in compresaion; but
t be somewhere in the thickness a neutral line
here was neither. That neutral line was about
the contact took place, and the outer surface
g under great tension and the inner under great
npression, there must be a tremendous pressure of
e surface on the other, and that made the joint
tight, whether the pressure inside the tube were great or small. He had seen the different sections of metal for the tube, and the way it was produced by successive molettes or rollers, and to watch the action of the machine itself was exceedingly interesting. At one end you saw a plain strip of steel going in; it passed through successive rollers and round a drum, on which friction was produced sufficient to drag it forward, and it came out with some six right-angled corrugations formed on it; then it went on to the mandrel, and gradually wound itself up into a tube of indefinite length. He had seen a great many machines, but never one which gave him so much gratification to look at, producing a most beautiful flexible air-tight tube, which was almost perfection.

Professor ELGAR, LL.D., said this invention would be very important in many ways for marine engines. The tightness of the tube under pressure, he thought, might be due to a similar action to that which took place with an ordinary cup and leather washer in a hydraulic engine. Any internal pressure must tend to open out the parts of the pipe at the joints, and the greater the pressure the more tightly would the surfaces be pressed together. It would be the same with external pressure, there would still be the cup and washer action. There could be no better test of the tightness of a joint than petroleum, for it was constantly found that tanks which would stand any amount of water pressure, when filled with petroleum were not tight. If the life of a tube made on this principle proved to be a long one under steam pressure, it would be a most valuable invention, but he did uot know how far the deposit, which always took place after continuous working with steam or water, would affect the flexibility.

Mr. LORRAIN said Mr. Imray's suggestion was one which required some consideration—being put forward at the moment he did not quite follow it; and it seemed to him that if the effect was due to the compression at the bottom of the ribbon and the tension at the top, the greater the distance between the datum or median line and the extremes, the greater would be the resistance to leakage. That might be discovered by trying strips in which the depth of the pockets varied. If Mr. Imray's theory were correct, it seemed to him that the deeper the pockets, the greater should be the resistance.

Mr. IMRAY intimated his dissent.

Mr. LORRAIN said he might have misunderstood Mr. Imray. It occurred to him that passing steam through the pipe under considerable pressure would produce a couple which would tend to pull the outer strip round in the direction of the hands of a clock, which would increase the pressure between the two surfaces.

Mr. WALTON said he had no doubt some deposit would take place in steam pipes after a time, but, as yet, they had found no inconvenience from this in their own practice.

Mr. C. U. GRAY doubted whether this tube would be useful for electrical purposes either for the shore ends or cables, or otherwise. The shore end of a submarine cable was subjected to very rough usage on a rocky shore, and if this tube got fouled by any rock or projection, it might open up the metal, and allow that great enemy of submarine cables, the *teredo*, to enter and feast on the internal core. To cover an ordinary cable with a tube of that kind seemed somewhat risky for two reasons; though the tube might be perfectly tight, it would be impossible with so many jonts in a long length to

prevent moisture, and in some cases gas, permeating into the cable and interfering with the insulation or destroying the insulating material. Another thing was that by bringing two metals together which had been subjected to a strain for some time, so that they were in a distinctly different molecular condition, you might set up an electrical action which would corrode and wear the joints. He feared that if used for steam the continued expansion from change of temperature would in course of time interfere with the shape of the coils, and that would lead to leakage.

Mr. PEREGRINE BIRCH thought the reason for the resistance to internal pressure might be what Mr. Imray suggested, but he did not see how it would account for tightness against external pressure, which he understood was equally marked. He should like further information on that point.

Mr. H. EDMUNDS said that some eighteen months ago, as a cable manufacturer, he saw in the discovery a means of improving the present method of armouring or protecting cables. The ordinary stranded wire armour had the disadvantage that the strands being parallel there was an opportunity for anything to pierce in between the strands—to get in between the joints of the armour. Any hard solid metal, such as iron or copper, was not flexible, and lead was too soft; but this flexible tube seemed to afford a solution of the problem. He did not know that it would be particularly applicable for the shore ends of submarine cables unless further protected by wire strands; but if you were wiring a building, it would be very serviceable. If you put a wire in a plaster wall, some one might drive a tack into it; and a nail would go through the strands of a wire armour, or even a leadpipe, but not through this steel tube. On the other hand, there was the question of durability to be considered; in a dry situation it might be considerable, but he did not know how long it wonld resist damp, oxidation, and rust.

Mr. WALTON said he had made the following experiment with regard to exterior pressure:—While there was a pressure inside one of these tubes of 40 lbs. to the square inch, he told a workman to hammer the tube out into an oval; that was done for about four inches; and there was not the slightest leakage. It was then hammered back again into its original shape, and it still remained tight.

Mr. BATCHELOR asked if the tube would still retain its flexibility under a pressure of 2,000 lbs. That would be very important in some cases, as in the use of a hydraulic rivetter, where you wanted to follow the work.

The CHAIRMAN said the late Sir William Siemens had made an armour for electric cables by winding a strip of copper spirally round them, and that was used to a considerable extent, but there was no pretension that it was absolutely water-tight. This subject was evidently one of very great importance, but he did not think a flexible tube need be called upon to fulfil all the functions of every tube ever made, including rigid tubes, and therefore it did not appear to him that the merit of this invention should be judged of by inquiring whether it was suited for every possible purpose. There were many cases in which a flexible tube was an absolute necessity, and the question was whether this tube was, for certain purposes, an improvement on anything they had before possessed. Lord Armstrong said on one occasion, when the Giffard injector was a novelty, that it was a thing which no fellow could understand, and he felt inclined to say much the same of this paper, until he heard Mr. Imray. He was not quite sure, even now, that he understood it, but he got a glimmering from Mr. Imray's explanation, though even Mr. Imray did not seem to put it forward with any great confidence. But as usual with anything he put forward, if not absolutely convincing, it was certainly worth serious consideration. To his mind it was a most hardy idea to take a metal, such as soft steel, make numerous convolutions of it, amounting to as many as forty or fifty in a foot, thus having the same number of opportunities for leakage, and yet so to make it that, when finished, the tube was absolutely tight in every part. He did not know how to express his admiration for the ingenuity brought to bear on the subject, but nothing but continued use would enable one to say how it would ultimately stand the various accidents of rough usage and deposits to which it would be exposed; or how far the rough internal surface would affect the flow of liquids. All this had to be borne in mind; but, after all, if you had a tube which was flexible and tight at variou[s] pressures—including low pressures—which could [be] used in laboratories without the danger of [being] trodden on and so extinguishing the gas, w[hile] leaving the gas to escape, which was a [source] source of explosions, it appeared that it [was a] most valuable invention. He concluded by [pro]posing a cordial vote of thanks to Mr. Redgrave.

The vote of thanks having been carried unanimously,

Mr. REDGRAVE, in reply, said one or two points had been raised which evidently arose from the diagrams being misunderstood. The two colours were only used for the sake of distinctness, there being in fact only one continuous strip of metal wound on itself. In the earlier forms the tightness depended to a great extent on a strip of rubber that was gradually reduced until it became a mere thread of asbestos, embedded in what he might call the piston of the cylinder; but even that had now been done away with, and now rather a flatter section was used, in which there was no packing at all. One of the diagrams showed the

way in which the piston slid in the cylinder, when the tube was bent; but, from experiments he had made, it never seemed to go the full extent of its possible travel; so that the tightness would appear to depend on the side or flat surface, not on the end of the piston. Mr. Imray's suggestion was very interesting, and worth careful consideration; but he was not sure that it explained all the peculiarities of the tubing. The question whether it would be a satisfactory mode of protecting electric cables was perhaps rather a side issue. Its main advantage was flexibility combined with great strength and lightness, and very few tubes of this kind were required to stand an internal pressure of 2,000 or 2,500 lbs. per square inch. It could be used as a suction pipe for an ordinary pump, but it would not stand external pressure on a vacuum within to anything like the same extent as internal expansive force. At the same time, it would stand any ordinary pressure from outside without injury, the metal being so disposed as to bear the greatest pressure in that direction. With regard to degradation by atmospheric and other influences, it was quite possible such a thing might occur, but it conld be coated in various ways. Strips had been drawn through copper, showing it was possible to cover the surface with some non-corrosive metal, and he believed the Company were on the look out for some metal sufficiently tough and pliable to stand the hard usage necessary to produce the tube, and yet absolutely non-corrodible by ordinary agencies. The delta metal and manganese bronze were being experimented with, but the difficulty, as yet, was to get them sufficiently tough. The tubes, even when filled with liquids at high pressure, retained their flexibility to a great extent unimpaired.

Miscellaneous.

CHICAGO EXHIBITION, 1893.

The following letter from Mr. McCormick, the representative in this country of the Chicago Exhibition, has been received by the Secretary of the Royal Commission:—

World's Columbian Exposition,
Chicago, 1893.
London Offices, 72, Victoria-street, S.W.,
March 23rd, 1892.

Sir Henry T. Wood, Society of Arts, John-street, Adelphi, W.C.

DEAR WOOD,—There is no doubt as to the truth of what you say as to the new tariff affecting British exhibitors to an unreasonable extent.

In reply to your communication of yesterday, with enclosures from Messrs. Hulse & Co., Messrs. Hunter & English, and Messrs. Vickers, Sons & Co., as to the reply you might make to objections, I can only repeat what I have said before on many occasions, both private and public, that your manufacturers have not to look to the fostering or promotion of their trade in the United States, or to the profits to be derived from same, in considering the propriety, not to say necessity, of their making a great exhibit at Chicago in 1893. The question which will force itself upon them in the near future, and which will be accentuated at the Chicago Exposition, is, how far can they retain their present trade position in the rest of the world, that is outside the United States. Up to this time, and for some years to come, we have so much to do in the way of development of our own resources, building towns and cities, cultivating fields, bridging rivers, building railroads, developing internal navigation on lakes and rivers, and other lines of work too numerous to mention, that will require the labour of a great army of men, whose wants can be supplied, with the cheap transportation of to-day, for less money than we could provide for them at home, that for many years we must continue to exchange the product of our fields for your surplus manufactures, including articles of luxury, with the price of which our tariff does not interfere. As these great works begin to near completion, and the workmen engaged upon them must find employment and occupations which compete directly with the manufacturers who now find a large market in the United States, this market will not only grow less and less, but we will seek an outlet for our manufactures in fields hitherto held without competition by the British manufacturer. Already, in some lines, we are entering these fields and competing successfully with your manufacturers. It is not for me to urge these points upon those whom we would be glad to welcome as exhibitors at Chicago, though it is to our interests in the future that they remain away. It is rather for the Royal Commission, if its members view as I do, the importance to the British manufacturer of making a great exhibit at the Chicago Exposition, to lay before them the fact, which we fully appreciate, that we will demonstrate to the merchants from all over the world, whether or not we can supply them with such articles as they have to import to better advantage than those to whom they have gone hitherto to supply their every want.—Faithfully yours,

ROBERT MCCORMICK.

THE FRENCH PRESS.

According to the *Journal de la Société de Statistique de Paris*, the number of newspapers and periodicals of all kinds in France amounted on the 31st Dec., 1890, to 5,182, of which 2,002 were published in Paris, 3,009 in the various departments, and 171 in Algeria and the colonies. After Paris, in which city the number of papers and periodicals issued is quite exceptional, the departments in which the largest number are issued are those of the Gironde, 139;

Nord, 139; and Rhône, 132. On the other hand, the departments of the Hautes Alps and the Lozère only issue six and eight respectively. Of the 5,182 periodicals published in France, 1,640 are political newspapers, and 3,542 are miscellaneous journals and reviews. In the latter category are comprised religious papers, journals devoted to the arts and sciences, trade, sport, &c. The political journals of Paris, of which the various shades are so numerous, are difficult to classify, but in the provincial towns, out of the 1,402 newspapers 942 may be ranked as Republican and 460 Conservative. The departments which have more than 25 political newspapers are the following:—Nord, 60; Seine Inferieure, 42; Gironde, 40; Seine et Oise, 35; Eure, 33; Bouches du Rhône and Calvados 28 each; Aisne, La Manche, and Somme each 26, and the Alpes Maritimes, 25. As regards publications other than political, the classification is very different. The following is a list of the departments having more than 40:—The Department of the Rhône, 118; Gironde, 99; Bouches du Rhône, 95; Nord, 79; Haute Garonne, 46; Herault, 45; and the Alpes Maritimes, 40—in other words, these are the departments in which scientific or literary tastes appear to be the most developed. In this respect Paris appears to defy all competition, since out of 3,448 publications (non-political), there are 1,841 published in the city of Paris, while the whole of the provinces only issue 1,607. The number of political daily papers appearing in Paris is 87. Six of these cost twenty centimes the copy; fifteen cost fifteen centimes; seventeen, ten centimes; and the majority (49) are sold for five centimes a copy. Among the latter appears the *Petit Journal*, of which more than 1,100,000 copies are printed daily. One of the members of the Chamber of Deputies, M. Arène, has recently compiled a statement showing a comparison between Paris and other capitals of the number of political and non-political papers and periodicals issued. According to this statement, Paris heads the list with 2,002, of which 161 are political. London comes next with 563; New York with 231; Vienna, 67; Berlin, 66; Constantinople, 29; Madrid, 28; St. Petersburg, 22; and Rome, 21. Paris shows a considerable increase in the number of newspapers and periodicals published in 1890 as compared with 1880, for whereas in the latter year the number amounted to 2,995, in 1890 it was 5,182, an increase of 2,187, or 50 per cent. In the departments the same increase is observable, while in the colonies the number has been trebled.

SALT INDUSTRY IN THE ARGENTINE REPUBLIC.

Her Majesty's Consul at Buenos Ayres says in his last report that a new salt industry has recently come into prominence in the Argentine Republic, and one of the utmost importance to any country, so far as the welfare of its inhabitants is concerned. It has always been acknowledged that the Argentine Republic is extremely rich in natural salt, but as a rule it is too far removed from the seaboard to permit of its being properly and advantageously worked. The vast salt lakes, or "salinas," in the Rio Negro valley, and lying some 22 miles from the harbour of San Blas on the Atlantic coast, form a singular exception to the rule. These great natural salinas are four in number, and in the aggregate measure about 20,000 acres of salt-bearing ground. The level of the brine is about 15 feet below the sea level at the port of San Blas. There are enormous mountains of rock-salt exposed to the action of the air at the foot of the Andes, and upward of 250 leagues from the salinas; and it is generally supposed that it is from these deposits that the salinas draw their supply of brine. All over the salinas there are numerous springs, and the surface of the salinas is covered by supplies from the natural springs. These salinas are covered with a singularly strong brine, its density being from 30 to 35 during the winter months—that is at least 30 times stronger than the sea water at San Blas, a distance of 22 miles. The district of Rio Negro is exceedingly favourable for the production of salt, the rainfall being less than in any other district in the Republic. The strong drying winds and sun soon turn what is a vast sheet of water into a frozen lake covered with white salt. The thickness of the salt is from two to four inches, but under that again is salt and sand of about equal proportions. The season for collecting is from November to March, and the process is an exceedingly simple one. The salt is gathered into small heaps, then removed to the adjoining banks and placed into large heaps, and there it remains in this condition until removed for shipment to the different markets in the Republic. A company, under a concession from the superior Government of the province of Buenos Ayres, has commenced to work these salinas, and they are now bringing into market large supplies of all qualities of salt suitable for the different trades (saladero, hides, and meat preserving), and also for household requirements. Their supplies are only limited by the means at present at their command, but they hope to be able to supply the great bulk of the wants of the country as well as the adjoining countries of Uruguay and Brazil. This company has also erected large works in Buenos Ayres for the purpose of preparing fine salt for table and kitchen use. It is fully expected in the near future, when these salinas are in full working order, that the surplus stock will be shipped to India and Australia.

Correspondence.

SPONTANEOUS COMBUSTION OF COAL.

Having very carefully studied the paper and the discussion on "The Spontaneous Combustion of

Coal," in the Society's *Journal* of March 4th, it would appear to me that all the more important facts contained in the paper and in the discussion lead to the conclusion that the pressure of the superincumbent mass is the chief factor—is the true hypothesis of what is termed "the spontaneous ignition of coal." For nowhere in that paper, nor in that discussion, is it stated that such heating takes place in the bunkers, on the sides or tops of the masses of coal; in those positions, in fact, that are most exposed to the chemical agencies which are generally supposed to be the causes of that ignition. But, on the contrary, the mischief is invariably found to originate deep down in the stowed masses, where it is difficult to get at. "The fire, as a rule," says Mr. Lewes, "begins near the bottom of the mass of coal." And elsewhere in the paper there are statements leading to the same inference, as, for instence, where it is said, "dig down, and get at the seat of the fire." Then we find that there have been cases "in which the crew have been deluded into the supposition that all was going on well, by finding normal temperatures at the surface of the cargo, when there was a tendency to heating at the bottom of the ship's hold." Again, "In the *Carr Rock*, at starting, the thermometer indicated 75° Fahr. in her hold; a month afterwards it was 98°, and in another month 120°, whereupon they dug down into the coal." We also find the expression, "Digging down to the seat of the fire," &c.

Moreover, the stress laid upon the increase of mass in producing the phenomenon of heating also favours the hypothesis of pressure. "But unless piled in unusually large heaps, and a great deal broken, it does not, as a rule, show signs of heating." Again, "it is found that liability to ignition increases with the increase in the mass of coal." The evidence demonstrating this very remarkable result is to be found in the Report of the Royal Commission for 1875, p. 8, and clearly shows the influence of mass. "It has been before shown that the cases of spontaneous ignition in masses of coal less than 500 tons does not amount to more than quarter per cent."

We have also to take into consideration that, in ships at sea, the superincumbent mass of a heap of coal is not a static mass, but more frequently a tremendous dynamic force, that has its direction frequently changed in a rough sea, the periodical rolling of the vessel giving rise to concussions within the masses of coal from various accidents in the distribution of those masses in lading. Pressure and concussion are the physical causes of heating in other substances than coal. Heating is, indeed, the equivalent of such forces. All vegetable products packed in bulk, either green or dry, are liable to heating, and this, as in coal, deep down in the mass. Coal, indeed, is but a vegetable product in a changed state, though still containing all its original elements locked up; these elements, however, become relatively plastic under pressure. The origin of volcanic action will, in all probability, be ultimately traced to the pressure of vast superincumbent masses.

The means to avert the terrible loss of lives, of ships, and of cargoes, is obvious enough, but I will leave suggestions for the prevention of such catastrophes to some future time.

W. CAVE THOMAS.

8, Fitzroy-street, W.,
12th March, 1892.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at Eight o'clock:—

MARCH 30.—EWING MATHESON, "Foreign Exchange." JOHN BIDDULPH MARTIN, Member of Council, will preside.

APRIL 6.—ROBERT S. MCCORMICK, Resident Commissioner for Great Britain from the World's Columbian Exposition, "The Future Trade Relations of Great Britain and the United States."

APRIL 27.—Prof. ROBERT WALLACE, "Egyptian Agriculture."

There will be no meeting on April 13.

Papers, the dates of reading of which are not yet fixed:—

"The Fisheries Department: its Position and Prospects." By J. W. WILLIS BUND.

"The Congo State." By Captain V. LOVETT CAMERON, R.N., C.B.

"Colour Blindness." By Captain W. de W. ABNEY, C.B., F.R.S.

"Uses and Applications of Aluminium." By G. L. ADDENBROOKE.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

APRIL 7.—Dr. J. AUGUSTUS VOELCKER, "The Agricultural Needs of India."

APRIL 28.—Sir WILLIAM WEDDERBURN, Bart., "Reorganisation of Agricultural Credit in India."

MAY 19.—JERVOISE ATHELSTANE BAINES, I.C.S., Chief Census Commissioner for India, "The Indian Census of 1891." Sir CHARLES BERNARD, K.C.S.I., will preside.

FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at Eight o'clock:—

APRIL 5.—The Rev. JOHN MCLEAN, D.D., "The Red and White Races in Manitoba and the North-West." Sir CHARLES TUPPER, Bart., G.C.M.G., C.B., will preside. The paper will be illustrated by lantern slides, and a collection of Blackfoot and Sioux Indian articles.

APRIL 26.—Sir EDWARD BRADDON, K.C.M.G., "Australasia: its Progress and Resources."

MAY 24.—Colonel HOWARD VINCENT, C.B., M.P., "The Extension of Colonial Trade."

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock:—

MARCH 29.—E. ROSCOE MULLINS, "The Decorative Uses of Sculpture." ALFRED GILBERT, A.R.A., will preside.

APRIL 12. — C. PURDON CLARKE, C.I.E., "English Brocades and Figured Silks." The LORD MASHAM will preside.

MAY 17.—GEORGE J. ROBINSON, "Decorative Plaster Work" (II.). J. HUNGERFORD POLLEN will preside.

MAY 31.—WILLIAM DE MORGAN, "Lustre Ware."

CANTOR LECTURES.

Monday evenings, at Eight o'clock:—

BENNETT H. BROUGH, Assoc.R.S.M., F.G.S., "Mine Surveying." Three Lectures.

LECTURE I.—MARCH 28.—*Introductory.*—Nature of mineral deposits, and the modifications of the methods of surveying required in different mines—Accidents due to inaccurate surveying—Historical sketch—The oldest mine plan—The divining rod—The use of the magnetic needle in mapping deposits of iron ore.

LECTURE II.—APRIL 4.—*Surveying.*—The compass—Ancient forms of compass—Various forms of miner's dials and theodolites—Use of aluminium for mine-surveying instruments—Supply of light for reading the verniers underground.

LECTURE III.—APRIL 11. — *Levelling.* — The level and staff for underground use—Applications of levelling in mining operations—The Carrara marble railway—Aërial wire ropeways—Hydraulic mining ditches—The St. Gothard, Mont Cenis, and Croton aqueduct tunnels—The Ernst-August adit-level—Mapping bore-holes.

DR. PERCY FRANKLAND, F.C.S., "Recent Contributions to the Chemistry and Bacteriology of the Fermentation Industries." Four Lectures.

May 2, 9, 16, 23.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MARCH 28...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Bennet H. Brough, "Mine Surveying." (Lecture I.)

Royal Scottish Society of Arts, George-street, Edinburgh, 8 p.m. 1. Report of Committee on Mr. Laing's paper, "Distillations of Mineral Oils. 2. Report by Committee on Mr. Sutter's paper. "A Rapid Destructor for Town's Refuse." 3. Mr. John Ritchie, "On the Application of Electricity to Hoisting Machinery." 4. Mr. E. A. Browning, "On Electric Pumping and Haulage in Collieries."

Chemical Industry (London Section), Burlington-house, W., 8 p.m.

Surveyors, 12, Great George-street, S.W., 8 p.m. Professor E. Kinch, "The Valuatiou of Feeding Stuffs and Foods."

Geographical, University of London, Burlington-gardens, W., 8½ p.m.

Actuaries, Staple-inn-hall, Holborn, 7 p.m.

Victoria Institution, 1a, Adelphi-terrace, W.C., 8 p.m.

East India Association, Westminster Town-hall, S.W., 3 p.m. Mr. A. Cottrell-Tupp, "The Effect on the Finances and Commerce of India of the Fall in the Value of Silver."

TUESDAY, MARCH 29...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr. E. Roscoe Mullins, "The Decorative Uses of Sculpture."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. Victor Horsley, "The Brain." (Lecture XI.)

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. A. R. Binnie, "Mean or Average Annual Rainfall, and the fluctuations to which it is subject."

WEDNESDAY, MARCH 30...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Ewing Matheson, "Foreign Exchange."

Chemical Society, Burlington-house, 4 p.m. Anniversary Meeting. Address by the President.

Patent Agents, 19, Southampton-buildings, W.C., 7.15 p.m. Mr. J. Imray, "Provisional Protection."

Civil and Mechanical Engineers, Westminster Chambers, S.W., 7 p.m. Mr. A. Wollheim, "Modern Sewage Precipitation Works: their Design, Construction, and Management."

THURSDAY, MARCH 31...Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Dr. B. A. Whitelegge, "Epidemic Waves." (Lecture II.)

United Service Institution, Whitehall-yard, 3 p.m. Lieut.-Colonel N. L. Walford, "Field Howitzers and Mortars."

FRIDAY, APRIL 1...National Indian Association (at the HOUSE OF THE SOCIETY OF ARTS), 4½ p.m. Annual Meeting.

Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting, 9 p.m. Professor Oliver Lodge, "On the Motion of the Ether near the Earth."

Geologists' Association, University College, W.C., 8 p.m.

Philological, University College, W.C., 8 p.m.

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Physical, Science Schools, South Kensington, S.W., 5 p.m.

SATURDAY, APRIL 2 ... Saturday Lecture Society, Lecture Theatre, South Kensington Museum, S.W., 3 p.m. Prof. Norman Lockyer, "Astronomy and Mythology of the Ancient Egyptians." Lecture II.

Royal Institution, Albemarle-street, W., 3 p.m. Dr. J. F. Bridge, "Dramatic Music from Shakspere to Dryden." Lecture II.

The Telegraphic Address of the Society of Arts, and of the Royal Commission for the Chicago Exhibition, is "Praxitèles, London."

Journal of the Society of Arts.

No. 2,054. Vol. XL.

FRIDAY, APRIL 1, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

CANTOR LECTURES.

Mr. Bennett H. Brough, Assoc.R.S.M., F.G.S., delivered the first lecture of the course on "Mine Surveying" on Monday evening, 29th inst. The lectures will be printed in the *Journal* during the autumn recess.

Chicago Exhibition, 1893.

FINE ARTS COMMITTEE.

A meeting of this Committee was held on Friday, the 25th inst. Present:—Sir Frederick Leighton, Bart., P.R.A., Chairman; Henry William Banks Davis, R.A., F. Seymour Haden, Sir James D. Linton, P.R.I., H. Stacy Marks, R.A., Walter William Ouless, R.A., Lumb Stocks, R.A., Marcus Stone, R.A., the Earl of Wharncliffe, with Sir Henry Trueman Wood, Secretary to the Royal Commission, and J. W. Beck, Secretary to the Committee.

LADIES' COMMITTEE.

A meeting of the Ladies' Committee was held on Friday, the 25th ult., at 53, Berners-street. Present:—H.R.H. Princess Christian of Schleswig-Holstein, President of the Committee, in the chair; the Marchioness of Salisbury, the Countess of Aberdeen, Lady Agnes Burne, Lady Knutsford, Lady Galton, Lady Jeune, Lady Roberts, Mrs. David Carmichael, Mrs. Bedford Fenwick, Miss Forsyth, Mrs. Priestley, Mrs. Roberts-Austen, Miss Emily Shaw-Lefevre, Miss Webster, with Miss Fay Lankester, Secretary of the Committee.

ELECTRICAL COMMITTEE.

A meeting of the Electrical Committee was held on Monday, the 28th ult. Present: William H. Preece, F.R.S. (Chairman); Sir Frederick Abel, K.C.B., D.C.L., D.Sc., F.R.S., Prof. W. Grylls Adams, M.A., D.Sc., F.R.S., Major-General E. R. Festing, F.R.S., Prof. George Forbes, M.A., F.R.S., Prof. David E. Hughes, F.R.S., Prof. John Perry, D.Sc., F.R.S., Alexander Siemens, C. E. Spagnoletti, Major-General C. E. Webber, C.B., Peter William Willans, James Wimshurst, with Sir Henry Trueman Wood, Secretary to the Royal Commission.

MAURITIUS COMMISSION.

The Governor of Mauritius has informed the Chairman of the Royal Commission of the appointment of the following local Committee, to make the necessary arrangements for the representation of Mauritius at the Chicago Exhibition:—The Hon. Sir V. Naz, K.C.M.G. (Chairman); the Hon. W. Newton, Q.C., the Hon. C. F. H. Adam, the Hon. W. T. A. Edwards, M.D., the Hon. J. Fraser, C.M.G., the President of the Chamber of Agriculture, the President of the Chamber of Commerce, L. Antelme, jun., G. Bouic, A. Daruty de Grandpré, F. Nash, C. Poupinel de Valencé, M.P., and A. Wemyss. The Governor has appointed Mr. W. Arthur Edwards, member of the Royal Agricultural College, Cirencester, to be agent for Mauritius at the Exhibition.

APPLICATIONS FOR SPACE IN THE BRITISH SECTION.

Intending exhibitors are reminded that applications for space must be made immediately, as the allotment of space is now proceeding. Most of the available space is now occupied, and no time should therefore be lost by manufacturers desiring to be represented.

All applications must be made upon forms to be obtained from the Secretary of the Commission at their offices, Society of Arts, John-street, Adelphi, London, W.C. They must be sent in, properly filled up, and addressed to the Secretary, as above.

Proceedings of the Society.

INDIAN SECTION.

Thursday, March 24, 1892; Sir JOHN STRACHEY, K.C.S.I., C.I.E., in the chair.

The paper read was—

THE OPIUM QUESTION.

By G. H. M. BATTEN.
Formerly of the Bengal Civil Service.

The violent and persistent attack, by an English association, on one of the most valuable of the products of India, with the avowed object of sweeping it from the face of the earth, renders it the duty of everyone who has the welfare of India at heart to examine the grounds on which that attack is made. Having for a long period served the Government of her Majesty the Queen in India, and having had special opportunities of making myself familiar with the facts relating to Indian opium, I accepted the invitation of this Society to read a paper on the subject, with the desire to help, so far as in me lies, to clear away the widespread ignorance of it which prevails in this country.

Apart from moral considerations, the question, so far as India is concerned, is generally discussed as if it were one affecting only the public resources of the Indian Administration, but it is much more far-reaching. The amount of revenue realised is but a part and not the greater part of the actual pecuniary value of the poppy crop and its products, while the well-being and happiness of hundreds of thousands of the people of India would be greatly affected by its extinction. I propose in this paper first to show the real value of that crop, and what it is that India is asked to sacrifice in order to satisfy the theories of a party of English philanthropists, whose excellent intentions in the cause of morality are only equalled by their determination to ignore all but the one side of the question, on which they have fixed their attention, and which serves their purpose.

It must be admitted that one of the surest signs of the progressive prosperity of a country is the increase of its external trade. The conditions which favour the development of foreign commerce are peace and liberty; the establishment of good and equable laws and their just administration; the utmost freedom, consistent with the rights of others, to individuals in utilising the sources of production at their disposal; the extension of facilities of communication within the country and with other countries; lightness of taxation—in a word, all the conditions of good government. Tried by this test, the British Government of India can show a splendid record. So long as the exclusive trading privileges of the East India Company existed they acted as a check on the free development of foreign trade, but on their final abolition in 1833, when the trade of India was thrown open to the mercantile world, it rapidly increased. In 1833-34 the value of the total exports of merchandise from British India was under Rx. 8,000,000 sterling. In fifteen years after that, they had about doubled. The increase then became more rapid, and, when assisted by the extension of railways in India, advanced by leaps and bounds. In the year 1890-91 the value of merchandise exported from India was over Rx. 100,000,000, or more than sixteen times the exports of 1833-34.

Long before British rule was established in India, opium was exported thence to China, and the trade in it, in common with all other trade, naturally developed under that rule. In the five years ending with 1833-34, the average quantity of opium exported was about 17,500 chests. The highest point to which it has ever attained was in 1879-80, when 105,508 chests were exported, but the present average is about 90,000 chests. Thus, while the general exports have increased fifteen fold, opium exports have increased only about five and a half times in volume in fifty-seven years. The cause of this will be found in the restrictive measures of the Government of India, to which I shall presently refer.

India is essentially an agricultural country, and nearly the whole of its exports consists of products of the soil. One of the most important and valuable of these products is the opium-yielding poppy. It is impossible to state with accuracy when this plant was first introduced into India. There is little record of its early history, but it is known that the Muhammadans had succeeded, in the 15th century, in introducing the cultivation of the poppy into Cambay and Malwa, and that when the Emperor Akbar, in the latter half of that century, established the Moghal Empire over Central India, he found Malwa opium a characteristic product of that country.

Dr. George Watt, who has recently compiled a complete monograph on the subject of opium, which has been printed by order of the House of Commons, points out that Abul Fazl (the historian of Akbar's times) "specially

states that poppy culture was chiefly practised in Fatehphur, Allahabad, and Ghazipur. We learn that the founder of the Moghal civil dynasty and his successors regarded opium as of necessity a State monopoly. They found it, however, at once the most convenient and successful course to farm out the right to manufacture and to sell the drug."

Dr. Bernier, the French traveller, who was in India from 1656 to 1668, speaking of the Rajputs and their martial qualities, wrote: 'From an early age they are accustomed to the use of opium, and I have been astonished to see the large quantity they swallow."

Tavernier, who was in India at the same period, incidentally mentions the Dutch trade in opium, which they obtained from Burhanpur in exchange for their pepper.

Captain A. Hamilton, in 1727, wrote: "The Chiefs of Calicut for many years had vended between 500 and 1,000 chests of Bengal opium yearly up in the inland countries, where it is very much used."

The Abbé Raynal, in 1770, described Patna as being the most celebrated place in the world for the cultivation of opium, and stated that, besides what was carried into the inland parts, there were annually 3,000 or 4,000 chests exported, each weighing 300 lbs.

There is ample evidence in the old records of the India-office, which have lately been examined by Sir George Birdwood, to prove that a large trade had been going on in opium between India and surrounding countries long before the East India Company, in 1773, undertook the supervision of the manufacture of opium in Bengal, Behar, and Orissa.

The Company, in fact, inherited from the Moghal Government this important and legitimate source of revenue on an article of luxury which India had shown itself capable of producing in high perfection, and for which there was a large demand both in and out of that country. At first they continued the system of farming out the exclusive right of opium manufacture, but this was found to entail many abuses. Amongst them was the pressure brought by the contractors, in spite of the most stringent regulations to the contrary, on the cultivators, whom they forced to carry on the cultivation, and whom they cheated in various ways. It also led to the adulteration of the drug and its illicit vend. The consequences were so injurious to the revenue, that, in 1797, the contract system was abandoned, and the Government assumed the monopoly of manufacture through its own agencies, a system which has remained in force until the present day. There was, indeed, at that time, no practicable alternative. The strongest opponent to the system of Government manufacture would hardly contend that the growth of the poppy and the manufacture of opium should have been left free and unrestricted, as that would infallibly have led to a great increase in the produce of the drug, and probably to its deterioration. On the other hand, if it ever entered into the conception of the Court of Directors to suppress, in the interests of morality, the cultivation of the poppy in the territories then in their possession, it is doubtful whether they would have had the power in those times to have done so, and it is certain that they could not have controlled the production of the vast poppy-growing tracts outside those territories in Malwa, Cambay, and elsewhere. The only result would have been that the opium consumers in India would have been supplied from sources outside British territory, and that the export trade would have been transferred to ports other than British. It would certainly have been impossible in those days to establish a Customs line to prevent the entry of opium into the Company's possessions. The Company would have sacrificed its revenue, and no one would have been benefited except the people of the territories outside the Company's possessions, at the expense of those within them.

The State monopoly continues to be administered by the Bengal Government, although its operations now extend into the North-West Provinces and Oudh. Under it, no person may cultivate the poppy except with a license from the Government, and every cultivator is bound to sell the opium produced from his crop to the Government, in whose two factories, at Patna and Ghazipur, it is manufactured into the opium of commerce. A portion of the manufactured opium is retained for consumption in India through vendors licensed by the Excise Department, and the remainder is sold monthly, by auction, in Calcutta to merchants, who export it. The Government prescribes rules for the cultivation of the poppy, the manufacture, possession, transport, import or export, and sale of opium, and any contravention of such rules is subject to stringent penalties, which may extend to imprisonment for one year or fine of 1,000 rupees, or both. Poppy illegally cultivated, and opium the subject of any offence against the law, is liable to confiscation, together with the vessels, packages, and

coverings in which it is found, and their other contents, and the animals and conveyances used in carrying it.

Like most crops, the poppy is subject to wide seasonal fluctuations, which formerly greatly affected the market prices of opium, led to speculation and gambling amongst the buyers for export, and caused corresponding uncertainty in the Government revenue. When, owing to the shortness of the supply, the price in Calcutta rose high, the direct effect was to stimulate the production of other opium competing in the foreign market with the Bengal drug, and amongst these the native production of China. Thus—and I would call particular attention to this fact, as having an important bearing on the question before us—the diminution of the supply of Indian opium to China was an incentive to the extension of poppy cultivation in China. To remedy the evils thus arising from the uncertainties of the seasons, the Government decided, twenty-five years ago, to limit the sales of opium in Calcutta to a quantity which would permit the formation of a reserve stock in plenteous years to meet deficiency in years of scarcity.

In the six years previous to 1867, the number of chests sold in a year varied from 21,423 to 64,111, and the price from Rs. 1,449 to Rs. 956 per chest. In 1867 the system of regulating the quantities annually sold, with the view of preventing such extreme oscillations in the price, was commenced.

In 1869, owing to short crops, before there had been time to form a sufficient reserve, there were less than 45,000 chests brought to auction. Sir Richard Temple, who was in charge of the Financial Department, in his Budget statement, made the following remarks:—

"The Government of Bengal is taking active measures for increasing the supply of opium for the China market to 50,000 chests annually, and for securing a reserve supply which may assure the public as to the quantity to be brought to sale, and may conduce to the checking of undue speculation in prices. There is fear that unless the supply can be improved next season, after these two deficient seasons, the cultivation of the poppy in China itself will be stimulated. For some time past positive accounts have been received of the increase of this culture in China. So it is clear that unless Bengal produces enough opium the Chinese will raise it for themselves. And if the Chinese will have opium, they may as well get it first rate from us, as second rate at home, and they may as well consume it taxed as untaxed. Again, if they do not procure it from us, they might procure it from Asia. The culture of the poppy in Persia is increasing, and some 4,000 chests are exported annually from that country."

Here we have an exposition of the policy of the Government of India. Recognising the fact that the Chinese demand a large supply of opium, and that to whatever extent India was unable to satisfy that demand, it would be met, either by increase of the produce in China itself, or by increased imports from other countries, the Government of India has thought it right, in the interests of the people of India, to shape its measures so as not to lose the natural advantages India possesses in the superior quality of its produce. Any one familiar with the records of the Government of India relating to this subject, must admit this is a fair representation of its policy and motives, and that nowhere in those records can be found any indication of a desire to stimulate the consumption of opium by the Chinese.

In pursuance of this policy, the Government yearly regulates the extent of the poppy cultivation, guided chiefly by the market prices and the stock of opium in hand. No one is forced to grow a crop of poppy against his will. The sole inducement is the price offered by the Government for the produce. For the past ten years this price has been 5 rupees a seer, which is exactly equivalent to 2½ lbs. troy. The Government makes advances, not bearing interest, before the crop is sown, and from time to time during its progress, thus saving the ryots from the exorbitant demands of the village money-lender. The crop, which is sown in the autumn and gathered in the spring, succeeds an autumn crop usually of Indian corn. The yield of opium per acre varies. For the five years ending 1889-90, the average produce per acre was a little over 16 lbs. avoirdupois, which, at 5 rupees a seer, gave the cultivator a gross return of near 40 rupees per acre. In addition to this, he receives payment for the poppy flower petals and the stalks and leaves, which are used in the factory for packing the opium cakes. The total average annual payments by the Bengal Government to the poppy cultivators exceed Rx. 2,000,000.

Besides the produce purchased by the Government, the seeds of the poppy are an important article of consumption and commerce. They are eaten parched, or employed as a condiment in the preparation of food; but perhaps their chief use is for the expression of oil, for which purpose they are not only largely used

in India, but are exported in considerable quantities, chiefly to Belgium, France, and the United Kingdom. The average produce of seed per acre, after deducting what is required for sowing, is stated to be about 260 lbs., yielding, by native processes, from 80 to 100 lbs. of oil. This oil is edible, and is used largely in Europe, either as a substitute for, or adulteration of, salad oil. It is also used for illumination, mixing with paints, soap, and varnish making. The oil-cake is eaten by the poorer classes and by cattle, being rich in nitrogen. The young seedlings, which are removed at the first weedings of the crop, are sold and eaten as a salad. I may state that these by-products of the poppy crop are perfectly free from opium.

In spite, therefore, of the labour entailed in the culture of the poppy, which requires frequent watering, and in spite of the vicissitudes of the season, which greatly affect this crop, the cultivation is popular, and the refusal of licenses is looked upon as a grievance by the ryots, as well as the landowners, to whom they pay their rent.

As I have already stated, the cultivator is bound by law to deliver the whole of the opium produced to the Government agents. It is then manufactured at the factories at Ghazipur or Patna into the opium of commerce, under the supervision of the scientific experts who are employed by the Government. The greatest care is taken to preserve the purity of the drug and the uniformity of its consistence. It is owing to this care, added to the natural advantages of soil and climate, that Indian opium has maintained its high reputation in the Chinese market, where it is admitted by the practical test of price to be far superior to the drug produced in China. Sir Robert Hart, the Inspector-General in China, in a report written in 1881, states that "the native product sells for one-half of the price obtained for the foreign drug." By "consistence" is meant the per-centage of fine opium obtained after evaporating the moisture. The standard differs in the two agencies. At the Patna factory (Behar Agency) the standard is 75, and at Ghazipur (Benares Agency) the standard is 70, for what is called "Provision opium," that is, opium to be sold for export, while for Excise opium, intended for consumption in India, the standard at each factory is 90. By the end of July the manufacture is finished, but the airing and drying are continued until October, when it is formed into balls, weighing each 3½ lbs. avoirdupois, and packed in chests. Forty balls are allotted to each chest of provision opium, which thus contains 140 lbs. From the difference of consistence a Behar chest contains 105 lbs. of fine opium, while a Benares chest only 98 lbs. of fine opium. A chest of Excise opium from the superior consistence contains one cwt. of fine opium.

The Provision opium is sent to Calcutta, where it is sold for export at auction by monthly instalments. The average quantity sold annually for the five years ending 1889-90 was 55,349 chests. During the last three of these years, and to the end of 1891, it was 57,000 a year. During the present calendar year, 1892, it has been notified that not more than 54,000 chests will be sold. In determining the number of chests to be annually manufactured and sold, the Government is guided principally by the state of the reserve stock, the aim being to keep up a reserve equal to half a year's supply. It is also guided, as I have already stated, by the prices obtained at auction. If the prices rise much, production in China and Persia is stimulated, and it is necessary to increase the production in India to maintain its market; on the other hand, if the prices fall low, and opium becomes cheap, consumption is stimulated, and the production has to be restricted. The object of the Government, as I have explained, is to maintain, so far as possible, uniformity in the price, and thus to avoid fluctuations in the market and in the revenue.

The average annual auction sale proceeds for the five years ending 1889-90, were Rx. 6,267,703, giving the average of Rs. 1,132 per chest. In the year 1890-91 they fell below Rx. 6,000,000, owing to the extension of the cultivation in China. The published statistics of the exports of opium from Calcutta, closely conform to these figures, showing an average export of 56,388 chests, valued at Rx. 6,175,542.

The Bengal Government supplies the Excise Department not only in Bengal, but also in all the other Provinces, except the Madras and Bombay Presidencies, with opium for consumption in India. The average quantity so supplied is about 4,500 chests a year, and the price credited to the Opium Department is Rs. 7¼ a seer, equivalent to Rs. 435 a chest. The average receipts from this source amount to Rx. 200,000 a year. The opium is sold to the consumers through licensed vendors, to whom it is supplied at an enhanced price, and who have to pay fees for the licenses to vend. The average receipts by the local govern-

ments from this source amount to about Rx. 800,000 a year.

The declared value of the poppy seed exported from Bengal on the average of the five years ending 1890-91, was Rx. 175,000.

Summing up these figures, we obtain the following result for the Bengal poppy crop :—

	Rx.
Auction sale proceeds on opium for export	6,000,000
Excise opium credited to Opium Department	200,000
Receipts of Provincial Government from the vend of Excise opium	800,000
Value of poppy seed exported	175,000
Total Rx.	7,175,000

In order to arrive at the ultimate annual value of the Bengal poppy crop, we must add several items which cannot be precisely estimated. These are the profits to Indian merchants and shippers on the opium exported, the profits to the Indian vendors of Excise opium, the value of the poppy seed consumed in India as seed-oil or oil-cake, and of the young plants used as food, and finally, the value of the illicit opium, which, in spite of all precautions, the cultivators are able to pass into consumption. On a moderate estimate, the value of this large trade cannot be taken at less than Rx. 3,000,000, bringing up the annual total value of the Bengal poppy crop to over Rx. 10,000,000, or, say, £7,000,000 sterling.

The territory in which this crop is produced may be described as a belt of country between 500 and 600 miles in length, with an average breadth of 180 miles, running North-West and South-East, between the 78th and 85th parallels of longitude, and the 24th and 29th parallels of latitude. The total area may be taken at about 100,000 square miles lying in the Provinces of Behar (Bengal), the North-West Provinces and Oudh. The average area cultivated with poppy for the five years ending 1889-90 was 527,200 acres, but in the last of those years was only 482,557, or 754 square miles, only three-quarters per cent. of the whole tract referred to, and this for only half the year, as another crop is almost invariably obtained from the same land during the other half. In the year 1889-90, no fewer than 1,322,355 cultivators were employed on the crop, while over 3,000 Hindoos and Muhamedans were employed by the Government in the factories and administration of the department.

The only other province in British India, where the poppy is allowed to be cultivated, is the Punjab. It is there grown under license in nearly every district. In 1889-90, the total area so cultivated was 14,458 acres, or under 23 square miles. Formerly, an acreage duty of Rs. 2 per acre was charged throughout the province, but, under new rules, it may be increased to Rs. 8, and has been increased to Rs. 4 in several districts. The cultivator may dispose of his poppy crop standing, to license-holders, who extract the opium; or he may extract the opium himself, and dispose of it, or of the produce, in the shape of poppy heads, to licensed vendors. The average annual supply of opium from this source, for the three years ending 1889-90, was something over 1,650 maunds, which would be equivalent to 1,100 Bengal Excise chests, though, probably, the opium is less carefully manufactured, and is of a lower consistency. The poppy heads are used as an infusion, forming a poppy tea, which is drank by the Sikhs, who are forbidden by their religion to use tobacco in any form. The value of the Punjab poppy crop can only be estimated. The average retail price of the opium is about Rs. 20 a seer, or Rs. 800 a maund, so that, from this source alone, it yields Rx. 132,000 on the average annual produce. Adding the value of the poppy heads, seed, and other by-products, and of illicit opium, which cannot fall short of Rx. 18,000, we get a total of Rx. 150,000, or say £100,000.

Outside of British India, the cultivation of the poppy is confined to certain native States in Central India and Rajputana, and the territory of the Gaikwar. The opium there produced is known by the generic name of Malwa opium. There are no trustworthy statistics showing the acreage under poppy, or the total quantity of opium produced. After providing for the home consumption within the native States, which must be a very large quantity, as the habit of consuming opium there has been long established and is widespread, the remainder is consumed in those parts of British India not supplied with Bengal opium, also in Hyderabad and Mysore, or is exported by sea to China, the Straits Settlements, &c.

The importation of Malwa opium into British territory is subject to very stringent regulations. Previous to the year 1831, by separate treaties with the native States, the British Government reserved to itself a monopoly of Malwa opium, which was purchased by the British Resident at Indore, and sold by auction either at Bombay or Calcutta. But in that

year it was deemed advisable, chiefly on account of the large quantity of opium smuggled to the Portuguese settlements on the coast, to relinquish the monopoly (which involved much unpalatable interference in the internal affairs of the native States), to open the trade to the operations of private enterprise, and to substitute, as a source of revenue, the grant, at a specified rate of duty, of passes to cover the transit of Malwa opium through British territory. This rate was at first fixed at Rs. 175 a chest, but as the resources of the administration for the prevention of smuggling improved, the British Government have been enabled gradually to increase the pass duty until it amounted to Rs. 700 per chest. In fixing the rate, regard is had to the prices obtained for Bengal opium. If the rate be too low, Malwa opium is unduly favoured in its competition with Bengal opium, and if it be too high, not only is smuggling encouraged, but the price of Bengal opium rises, leading either to an increased cultivation of the poppy in Bengal or in China. The present rate on opium for foreign export is Rs. 600 a chest, except on a small number of chests, weighed at Ajmere, where the rate is Rs. 625. The rate on opium imported for local consumption in the Bombay Presidency remains at Rs. 700 per chest.

All opium transported out of the native States of Central India, Rajputana, and Baroda, has to be weighed and tested at scales established at convenient places in those States under the superintendence of officers of the British Government. The transport is permitted only under passes granted on payment of the duty and by certain specified railway routes. The annual quantity passed at the scales may be taken now at 30,000 chests. A chest of Malwa opium contains the same quantity as a chest of Bengal provision opium, namely 140½ lb. avoirdupois; but its consistency is considerably higher, being from 90 to 95 per cent. of fine opium. Consequently, it has a higher average value. The average exports for the five years ending 1890-91 were 32,540 chests, valued at over Rx. 4,000,000. The remainder of the Malwa opium leaving the native States—about 2,000 chests—is consumed in India, chiefly in the Bombay Presidency; but the Madras Presidency, Hyderabad, and Mysore are also supplied from this source, and some goes to the Punjab. The value of these 2,000 chests may be taken at about Rx. 250,000, making a total value, for 30,000 chests, of Rx. 4,250,000. To this must be added, as in the case of the Bengal opium, the profits of the merchants and shippers exporting the opium, and of the vendors in India, say nearly Rx. 1,500,000.

The average annual exports of poppy seed from Bombay are valued at Rx. 212,697. They amounted, in 1890-91, to Rx. 310,930. Thus, the total annual value of the Malwa opium brought into British territory, and of the Malwa poppy seed exported from India, cannot be less than £4,000,000.

There remains to be considered the value of the Malwa opium consumed in the native States of Central India, Rajputana, and Baroda; also the value of the Malwa poppy seed not exported from India, and of the other by-products of the crop. As I have already said, there are no data available for ascertaining or estimating the acreage under poppy cultivation in the native States in question, much less for determining the quantity and value of the whole products of that crop. The population of those States is 21,750,000, or about one-tenth of the population of the rest of India. We know that the people of these States have, for centuries, been in the habit of consuming opium, we know that the restrictions placed on the cultivation of the poppy, and on the vend of opium in British India, do not exist in these States, and we know that a vast quantity of opium is smuggled out of them. If we estimate the value of the crop, exclusive of the value of the product licitly exported, at £2,000,000, it will certainly be under the real value.

The total annual value of the poppy crops in India thus appears to be as follows:—

Bengal crop	£7,000,000
Punjab crop	100,000
Malwa crop, licitly consumed in British India and exported by sea	4,000,000
Malwa crop, consumed in Central India, Rajputana, and Baroda and smuggled thence	2,000,000
Total	£13,100,000

This is divided between the producers and manufacturers, the landlords, the British and native administrations, the middlemen, merchants, shippers, vendors, &c., of India, and is paid by the ultimate consumers, principally Chinese.

Before leaving the commercial side of the question, there is one point to which I should

like shortly to refer. It is the effect on the rupee exchanges which would be produced by the cessation of the opium trade from India to China. The disbursements of the Government of India in England, usually called the Home Expenditure, are now about £17,000,000 annually. In order to provide this sum, the Secretary of State draws bills on India, which are purchased by persons in England who have to make payments, chiefly for the purchase of produce to be brought from the East for sale here. The Secretary of State's Bills are, therefore, paid by the excess of exports from India over the imports to India. It is evident that, if there were a reduction in the excess exports from India, the demand for the Secretary of State's Bills would be *pro tanto* reduced, and the exchange value of the rupee would fall. India exports to China—including the Treaty Ports—annually, merchandise to the value of near 14,000,000 of tens of rupees, the greater part of which is opium, and imports from thence merchandise and treasure of the value of very little over 5,000,000. How and where is the account adjusted? It is in England, to which China sends tea, silks, and other produce. Practically, therefore, the opium sent by India to China is paid for by remittances from England to India, which form part of the demand for the Secretary of State's Bills. The cessation of this part of the demand would, therefore, have a very injurious effect on the rate of exchange at which those bills are sold, and would increase the heavy loss to which India is put by the rise in the silver price of gold.

Thirteen millions sterling is a very moderate estimate of the sum India is asked to sacrifice annually by suppressing her opium trade. The demand for this sacrifice is made not by the people of India, not by the people of China, not by the responsible administrators of those countries, but by an irresponsible party of philanthropists seeking to obtain their ends by the despotic action of the Parliament of the United Kingdom, in which India has no representatives.

What are the reasons put forth for demanding the despotic destruction by a foreign country of a valuable Indian industry which, besides satisfying an internal demand in India itself, provides one-tenth of the whole export trade of merchandise from India?

The basis of this demand is the hypothesis that, except for medicinal purposes, the use of opium is wholly pernicious, that it demoralises and ruins, body and soul, the consumer, and that it produces no countervailing benefits which for a moment can be compared with the evils it causes.

A second reason given is that the English people have created the demand for opium by the Chinese, that they have compelled the importation of Indian opium into China by force of arms, and that they are, therefore, morally responsible for the asserted degradation of the Chinese from the use of this drug.

I shall now proceed to examine the validity of these reasons, and I shall begin with the second.

If there is one fact more certain than any other connected with this question, it is that the people of China have used opium for centuries before the people of England had any voice in the affairs of India. A valuable "Historical Note on Opium in China" has recently been drawn up Dr. Edkins, of the Chinese Customs Service, and published by order of Sir Robert Hart, the Inspector-General of the Imperial Maritime Customs of China. From this note it appears that opium was first brought to China by the Arabs early in the 8th century, and it is frequently mentioned by Chinese writers of that time. It seems at first to have been valued for its medicinal qualities; but that it was not confined to this is proved by quotations from the Chinese poets of the 10th century. One, named Su Chê, writing on the poppy, which he grew in his garden, says:—

"It is sown with wheat, and ripens with panicled millet; when growing, it may be eaten like the vegetables in spring. The seeds are like autumn millet. When ground, they yield a sap like cow's milk; when boiled, they become a drink fit for Buddha. Old men, whose powers have decayed, who have little appetite, who, when they eat meat, cannot digest it, and when they eat vegetables cannot distinguish their flavour, should take this drink. Use a willow mallet and a stone basin to beat it. Boil it in water that has been sweetened with honey. It restores tranquility to the lungs and nourishes the stomach. For three years the door has been closed, and I have gone nowhere and come back from nowhere. I see here the 'Hermit of the Shade' (a Taoist priest) and the long-robed Buddhist priest; when they sit opposite I forget to speak. Then I have but to drink a cup of this poppy-seed decoction. I laugh, I am happy, I have come to Ying-ch'uan, and am wandering on the banks of its river. I seem to be climbing the slopes of the Lu Mountain in the far West."

Recipes for the use of opium medicinally appear from time to time in the works of

Chinese writers of every subsequent century. Barbosa, a Portuguese geographical discoverer, who wrote early in the 16th century, affords evidence that the Arabs had begun to grow opium in India, and that it was exported to Siam and Pegu; and that it was brought to Malacca by Arabs and Gentiles (Hindoos) to exchange for cargoes of Chinese junks. In the Chinese tariffs of 1589 and 1615 opium is entered and rated. After citing a mass of evidence on the subject, Dr. Edkins concludes that—

"It appears plain that from the latter part of the 15th century, the manufacture of native opium has existed in China; and it is not only in recent years that there has been both native and foreign opium in this country."

It was not, however, until the first half of the 17th century that the practice of smoking opium commenced in China. This practice followed on the introduction of tobacco which was brought to China about 1620. Dr. Edkins writes:—

"In the time of the last Ming Emperor, who reigned from 1628 to 1644, tobacco smoking was prohibited, but the habit spread too rapidly to be checked by law. The origin of opium smoking is thus accounted for. Various ingredients were in various countries mixed with tobacco to try their effect; among them was opium."

In spite of repeated prohibitory edicts the habit of tobacco smoking became almost universal.

"This immense popularity of tobacco smoking was an indication of the readiness of the Chinese nation to adopt the use of narcotics. The same thing which took place in the 19th century with opium smoking occurred in the 17th century with tobacco smoking. The Confucian mind was shocked, the sense of propriety was wounded; but this did not prevent the rapid spread of both these modes of indulgence in all circles. Prohibitory edicts were issued in vain by Emperors animated by paternal affection for their people."

Opium smoking seems first to have commenced in Formosa. A native author quoted in 1746 described the process of smoking opium mixed with tobacco and hemp. It was used as an aid to sensual indulgence. In the year 1729 an edict was issued on opium smoking, prohibiting under the severest penalties the sale of opium, and the opening of opium-smoking houses. From that time forward they have been in theory a crime, but in practice have never been so treated. Opium continued to be imported and passed at the Custom-houses, and the cultivation of the poppy in China continued to extend. It was not until 1773, after the conquest of Bengal by Clive, that English merchants took up the import trade, which had steadily increased in the hands of the Portuguese, and it was not until 1781 that the East India Company became the traders in the drug. In 1767 the imports into China are said to have reached 1,000 chests, and the duty was three taels a chest. The statistics of trade from India were not then registered with the care and accuracy introduced later by the East India Company. It will be seen that the Abbé Raynal, in 1770, gives an export of from 3,000 to 4,000 chests from Patna alone. It was nominally imported as a medicinal drug, but in practice was used as a medicine and for smoking. It is thus amply proved that the English are not responsible for the introduction or use of opium in China.

In the beginning of this paper I have shown that the extension of the opium trade is only a part, and not an undue part, of the general extension of foreign trade which has developed under the English administration of India. But, it is said, the English have forced this trade on the Chinese. The war with China, which terminated in 1842, has been called the Opium War, and its immediate cause was no doubt the seizure and destruction by the Chinese of a large number of chests of Indian opium belonging to English merchants. But contemporary history shows that the real objections of the Chinese were not to the import of opium, but to the necessity of paying for it in silver. Commander J. Eliot Bingham, who served in that war, and wrote its history, shows that the imports into China of opium, metals, cotton, &c., exceeded the exports of tea, silk, &c., by 2,500,000 sterling. The Chinese held the economic fallacy that this state of things was injurious to their country, as it drained away their silver. The Imperial edicts enlarged more on the abstraction of their sycee silver than on the injury from opium to the morals of the people. One high Chinese official memorialised the Emperor "to permit the barbarian merchants to import opium as a medicine, and to require that, after having passed the Custom-house, it shall be delivered to the Hong merchants only in exchange for merchandise, and that no money be paid for it;" and further, that the exportation of money and sycee silver be prohibited. But to whatever extent the wars with China were connected with the smuggling of Indian opium, it is certain that since 1858,

when the Treaty of Tientsin was signed the Chinese Government has had a perfectly free hand in the matter of the importation of opium. By that treaty certain commercial concessions were arranged which, included the legitimatising of the import of opium, subject to a duty being levied thereon. But in the treaty itself there was no mention of, or allusion to, the opium trade. Lord Elgin wrote that he intentionally abstained from urging any treaty recognition of that trade. The preparation of the tariff devolved on Mr. Lay, the Chinese Secretary to Lord Elgin's special mission, at the desire of the Chinese no less than that of Lord Elgin. Mr. Lay, in a letter to the *Times* of the 22nd October, 1880, wrote:—

"When I came to 'opium,' I inquired what course they proposed to take in respect to it. The answer was 'We have resolved to put it into the tariff as foreign medicine.' I urged a moderate duty in view of the cost of collection, which was agreed to. This represents with strict accuracy, the amount of 'extortion' resorted to. . . . . The Chinese Government admitted opium as a legal article of import, not under constraint, but of their own free will deliberately."

In the *Times* of the 25th of same month, a letter appeared from Mr. Laurence Oliphant, who was secretary to Lord Elgin's Mission, in which he confirmed the statement made by Mr. Lay. He says he, with the Commissioner appointed by the Chinese Government, went through the tariff elaborated by Mr. Lay with the subordinate Chinese officials:—

"When we came to the article 'opium' I informed the Commissioner that I had received instructions from Lord Elgin not to insist on the insertion of the drug in the tariff, should the Chinese Government wish to omit it. This he declined to do. I then proposed that the duty should be increased beyond the figures suggested in the tariff; but to this he objected, on the ground that it would increase the inducements to smuggling. . . . . I trust that the delusion that the opium trade now existing with China was 'extorted' from that country by the British Ambassador may be finally dispelled."

In 1876, a Convention or Agreement, called the Chefoo Convention, was arrived at between the Governments of Great Britain and China, in which the British Minister, Sir Thomas Wade, promised to move his Government to make certain special arrangements as to the import of opium. These arrangements were finally carried out by an additional Article, signed at London, in 1885. By this Article an addition to the import duty of 30 taels per chest was agreed to. It amounts to a further 80 taels per chest, and frees the opium from any further duty or tax whilst in transport in the interior, being, in fact, a composition of the *likin* tax. When the package is opened at the place of consumption, it is subject to any tax which may be levied on native opium.

During the three years ending 1890, the average import of opium into China was 78,360 piculs or chests, valued at 30,577,235 Haikwan taels. The average import duty was 2,355,650 taels; the opium *likin*, 6,278,922 taels, making a total receipt averaging 8,634,572 Haikwan taels per annum. What is called the par value of a Haikwan tael, measured in gold, is 6s. 8d., that is, there are three such taels to the pound sterling. At this rate, the receipts of the Chinese Government from the import of opium are equivalent to £2,878,000 a year. The great appreciation which has taken place in the value of gold has, of course, lowered the exchange value of the silver tael, and this, no doubt, affects China in the payment of debts to gold standard countries; but for internal purposes, the value of the tael has been little affected. This large revenue, equal now to about £2,000,000, and forming more than one-third of the entire Customs revenue of China, is collected by the department presided over by Sir Robert Hart—a department admirably administered, and scrupulously accounting for its collections to the Imperial Government at Pekin. The *likin*, for which the payment of 80 taels per chest is a composition, was formerly collected as transit duties by the local Chinese authorities through whose provinces the opium passed. The Imperial Government received only such portion of the collections as they could manage to get out of the Provincial Governments, who, on the other hand, strove to retain as much as possible. The arrangements under the Chefoo Convention are, therefore, very advantageous to the Imperial Government at Pekin, which cannot afford to dispense with this large revenue derived from the import of opium.

Another result of the Chefoo Convention has been greatly improved arrangements for the prevention of smuggling of opium from Hong Kong. A mixed Commission was appointed, including a Chinese officer of high rank, which resulted in an Ordnance of the Hong Kong Legislature passed in May, 1887, by which the movement of opium into, within, and from Hong Kong is strictly regulated with the view to the prevention of smuggling into China.

It is clear then that Indian opium is now imported into China with the full approval and consent of the Chinese Government, who are at liberty to terminate the present arrangement at any time by giving twelve months' notice of their desire to terminate it. It is equally certain that Great Britain would never fire a gun to force Indian opium on the Chinese.

I have already referred to the early history of opium in China. Sir Robert Hart said, in 1881, that "Native opium was known, produced, and used long before any European began the sale of the drug along the coast." The production of opium in China has gone on steadily increasing, and has been encouraged by the restrictions and heavy taxation placed on India opium by the Government of India. All travellers and the Consular authorities testify to the vast areas under poppy cultivation. The produce of native opium has been estimated to be from three to ten times the quantity of the imported drug. Chinese opium is now much better prepared than it formerly was, and it has practically driven Indian opium out of the markets of Northern China, and, so far as we know, it supplies the bulk of the demand in the inland and western provinces. The local drug is much cheaper than imported opium. The Burma revenue officers are constantly striving to prevent importation of cheap Chinese opium into Burma.

Of the numerous recent travellers in China, I will quote only Mr. Hosie, a Consular Agent, who, in 1883, travelled from February to June through the provinces of Sse-ch'uan, Yünnan, and Kueichon. His diary has almost daily references to the extensive poppy cultivation through which he passed. In many places, it was the principal crop. With regard to the Government prohibition, he writes :—

"I have noticed in several places west of the provincial capital a proclamation dated the 9th November, 1882, by the Governor-General of Sse-ch'uan, prohibiting the cultivation of the poppy, and enjoining a more extended sowing of the cereals. It was always more or less mutilated, whether intentionally or not I cannot say. At all events, poppy was frequently growing on the side of the road opposite to that on which the proclamation was posted. It is one thing to issue instructions, another to see that they are carried out."

The prohibition is evidently in the nature of a pious opinion, meant for show and not for use.

Mr. Hosie, writing on the 5th June, 1883, says :—

"It seems superfluous daily to mention poppy as a crop. To-day, however, it was exceedingly prominent, growing everywhere on the hill-sides and bottom lands. Large rice bowls heaped with the drug were exposed at the door of almost every shop in every hamlet and village, not a bowl here and there, but several, eight being a very common number. In fact, the whole country reeks and stinks of opium."

With these facts before us, how can it be maintained that the consumption of opium in China can be affected by the imports of Indian opium, except in so far that these supply a purer and more expensive article, the suppression of which would lead to larger products of native opium of inferior quality?

I will here quote the opinion of the Rev. F. Galpin, of the English Methodist Free Church, a respected missionary at Ningpo, an important port on the east coast of China. When asked, about ten years ago, to join in a petition to the House of Commons against the opium, he refused to do so, and, in his letter of refusal, wrote :—

"I beg to express my hearty dissent from the idea presented in the petition, that the Chinese people or Government are really anxious to remove the abuse of opium. The remedy has always been, as it is now, in their own hands. Neither do I believe that if the importation of Indian opium ceased at once, the Chinese Government would set about destroying a very fruitful means of revenue. On the contrary, I feel sure that the growth of Chinese opium would be increased forthwith."

I could multiply to any extent the evidence of the extensive cultivation of poppy in China, but I think I have said enough to show that it is a fact which cannot be denied.

I will now proceed to discuss the crucial question as to the effects of consuming opium, of which there are various forms. In China the usual form is by what is called smoking opium. In India it is eaten. In Europe it is drunk in the form of laudanum, or a tincture prepared in spirits of wine. We must consider what is the effect on the average consumer, and not confine our attention to the cases of those persons only who indulge in the habit to excess, cases which I shall show are exceptional.

The Anti-Opium Society look at only one side of this question, and they arrive at their conclusions by generalising over the whole number of opium consumers the results observed or recorded in the case of frequenters of what are called "opium dens." Even in these cases they make no allowance

for the fact that many of the indulgers in the drug have been led to the habit by painful diseases, from which they have sought and found relief in opium, and that these diseases —not due but antecedent to the resort to the drug — largely account for the wretched appearance and condition of the patients. This is much as if one who derived his knowledge of the effects of alcohol solely from the gin palaces or lower drinking shops in London, should conclude that habits of intoxication, brutality, and social and physical degradation there to be seen, were typical of the mass of alcohol consumers in England; in short, that every one who was not a total abstainer was a confirmed drunkard. We know this is untrue, and that the great body of Englishmen, whether of the upper or the working classes, take their liquor in moderation and with positive benefit to themselves. So, too, with the consumers of opium in China and India. To prove this, there is the evidence of numerous Englishmen who have resided for a long time in those countries, and whose duty it has been to acquaint themselves with the facts. Some of this evidence I will put before you.

It may be safely said that all but a very small per-centage of the people of this country are absolutely ignorant of the normal effects of the habit of using opium. The popular ideas on the subject which prevail, are largely due to Thomas De Quincey who, in 1822, published the confessions of an English opium eater. Many have read this fascinating work, and many more have heard of it, and look upon De Quincey as the "shocking example" of such a habit. But I venture to say that his confessions completely disprove the allegations put forward by the opponents of the use of the drug. De Quincey (I am quoting Mr. Henry Morley) inherited a delicate and nervous constitution. His father died of consumption at the age of thirty-nine. In his youth he ran away from school, and, in the course of his subsequent adventures, passed through a period of hardship and want. He wrote, that while wandering in Wales, where he seldom slept under a roof, he was reduced to one meal a day.

"From the keen appetite, he says, produced by constant exercise and mountain air, acting on a youthful stomach, I soon began to suffer greatly on this slender regimen, for the single meal which I could venture to order was coffee or tea. Even this was at length withdrawn; and afterwards, so long as I remained in Wales, I subsisted either on blackberries, hips, haws, &c., or on the casual hospitalities which I now and then received in return for such little services as I had opportunity of rendering."

Soon after this he came to London.

"And now began the latter and fiercer stage of my long sufferings; without using a disproportionate expression, I might say, of my agony. For I now suffered, for upwards of sixteen weeks, the physical anguish of hunger in various degrees of intensity, but as little perhaps as ever any human being can have suffered who has survived. . . . Let it suffice to say that a few fragments of bread from the breakfast-table of one individual (who supposed me to be ill, but did not know of my being in utter want), and these at uncertain intervals, constituted my whole support."

To these hardships he attributes the pains, which subsequently drove him to the daily use of opium. In 1804, when he was just nineteen years of age, after suffering for about twenty days from excruciating rheumatic pains of the head and face, with hardly any respite, at the advice of a friend he took his first dose of laudanum. He thus describes the result:—

"That my pains had vanished was now a trifle in my eyes; this negative effect was swallowed up in the immensity of those positive effects which had opened before me—in the abyss of divine enjoyment thus suddenly revealed."

From this time, for about eight years, he regularly took laudanum, though not daily. He writes:—"And how do I find my health after all this opium eating?" And he thus answers the question:—

"If I dared to say the real and simple truth, though, to satisfy the theories of medical men, I ought to be ill, I never was better in my life than in the spring of 1812; and I hope sincerely that the quantity of claret, port, or 'particular Madeira,' which, in all probability, you, good reader, have taken and design to take for every term of eight years during your natural life, may as little disorder your health as mine was disordered by the opium I had taken for eight years between 1804 and 1812."

In this last year he suffered much in bodily health, from distress of mind connected with a very melancholy event, and in 1813 the internal pains he had suffered from in his boyhood again attacked him. He then began to take opium daily, and the habit so grew upon him, that in a few years he was taking it at the rate of 340 grains a day, or about half a pint of laudanum. With marriage in view, he gradually reduced it to 40 grains. In 1816 he married, and had a large family of

sons and daughters. He occasionally relapsed into excess of opium-taking, until the close of 1844. From that time he reduced his allowance to six grains a day, and in his latter years De Quincey's life passed peacefully, free wholly from distress of mind. He died in 1859, in his 75th year. Here we have, then, the instance of a man, of a naturally delicate and nervous constitution, whose early life was subject to great physical hardship, who from the age of 19 indulged in the use of opium—for a long period in excessive quantities—and who yet retained his mental qualities unimpaired, led an active literary life, was one of the most brilliant, accomplished, and intellectual writers England has produced, and who lived to the good age of 75 years.

Now what does De Quincey, with his unparalelled experience, say of the effects of opium-taking? Here are his own words with respect to its bodily effects :—

"Upon all that has hitherto been written on the subject of opium, whether by travellers in Turkey (who may plead the privilege of lying as an immemorial right) or by professors of medicine, writing *ex cathedrâ*, I have but one emphatic criticism to pronounce—Lies! lies! lies!"*

Again—

"It is not so much affirmed as taken for granted, by all who ever mention opium, formally or incidentally, that it does or can produce intoxication. Now, reader, assure yourself, *meo periculo*, that no quantity of opium ever did or could intoxicate. As to the tincture of opium (commonly called laudanum), *that* might intoxicate if a man could bear enough of it. But why? Because it contains so much proof spirit, and not because it contains so much opium. But crude opium, I affirm peremptorily, is incapable of producing any state of body at all resembling that which is produced by alcohol, and not in *degree* only incapable, but even in *kind*. It is not in the quantity of its effects merely, but in the quality that it differs altogether. . . . . The main distinction lies in this, that whereas wine disorders the mental faculties, opium, on the contrary (if taken in a proper manner), introduces amongst them most exquisite order, legislation, and harmony."

With respect to the allegation that the elevation of spirits produced by opium is necessarily followed by a proportionate depression, De Quincey simply denies it—

"Assuring my reader that for ten years, during I took opium at intervals, the day succeeding to that which on which I allowed myself this luxury was always a day of unusually good spirits."

Again—

"With respect to the torpor supposed to follow, or, rather (if we were to credit the numerous pictures of Turkish opium eaters), to accompany the practice of opium eating, I deny that also. Certainly, opium is classed under the head of narcotics, and some such effect it may produce in the end; but the primary effects of opium are always, and in the highest degree, to excite and stimulate the system. This first stage of action always lasted with me, during my noviciate, for upwards of eight hours; so that it must be the fault of the opium eater himself if he does not so time his exhibition of the dose (to speak medically) as that the whole weight of its narcotic influence may descend upon his sleep."

De Quincey, in fact, used to take his dose before going to the Italian Opera, as he found it greatly increased his mental activity and appreciation of the entertainment. He observes that it is remarkable that, during the whole period of years through which he had taken opium, he had never once caught cold (as the phrase is); not even the slightest cough. It was not until De Quincey commenced to wean himself from the habit of taking excessive doses of the drug, that he experienced what he calls the pains of opium. It kept its hold on him "by the tortures connected with the attempt to abjure it." Nevertheless, he succeeded, in a few weeks, in bringing down the quantities to a moderate amount. He writes—"the issue of my case is at least a proof that opium, after a 17 years' use and an 8 years' abuse of its powers, may still be renounced."

So much for the experiences of an English opium eater. They are quite consistent with the assertion that the moderate use of opium, by a person in good health, may be continued for years, not only without any harmful effects, but with absolute benefit.

Let us now see what is the effect on the Chinese, who resort to the more innocuous habit of smoking opium. In February, 1882, three lectures were given in St. James's-hall by the late Mr. William Brereton, and were subsequently published under the title, "The Truth About Opium." Mr. Brereton lived and practised as a solicitor for nearly fifteen years in Hong Kong, where he had daily experience of the custom and effects of opium smoking. He was in no way engaged in the opium trade, and had no pecuniary interest in it, but felt it his duty to endeavour to dispel what he called the unfounded delusions which have taken possession of the

* Since De Quincey wrote this, the views of the medical profession as to the effects of opium consumption (especially such members of the profession as have had wide experience in India and China) have greatly modified, and are now more in accordance with the conclusions of De Quincey.

public mind on the subject. His book is a storehouse of facts and arguments. It is written in a bright and intelligent style, and I strongly recommended its perusal to any one interested in the question. The facts have never been denied, or the arguments answered by any one having a personal knowledge of the subject. I shall take the liberty of quoting largely from this book.

Mr. Brereton commences by stating that, having had daily intercourse with the people from whom the best and most trustworthy information on the subject of opium and opium smoking could be obtained, his experience is that opium smoking as practised by the Chinese is perfectly innocuous, and that this is a fact so patent that it forces itself upon the attention of every intelligent resident in China who has given ordinary attention to the subject. He quotes numerous high authorities in support of this view. The first is Dr. Philip Ayres, Inspector of Hospitals of Hong Kong for many years, who both in India and in China made the subject of opium consumption a special study, and who had a large native practice amongst the Chinese.

In a report to the Government of Hong Kong for the year 1881, Dr. Ayres wrote :—

"I have come to the conclusion that opium smoking is a luxury of a very harmless description."

In an article of the "Friend of China," written by Dr. Ayres, he says :—

"My opinion is that it [opium smoking] may become a habit, but that that habit is not necessarily an increasing one. Nine out of twelve men smoke a certain number of pipes a day, just as a tobacco smoker would, or as a wine or beer drinker might drink his two or three glasses a day, without desiring more. I think the excessive opium smoker is in a greater minority than the excessive spirit drinker or tobacco smoker. In my experience, the habit does no physical harm in moderation. . . . I do not wish to defend the practice of opium smoking, but in the face of the rash opinions and exaggerated statements in respect of this vice, it is only right to record that no China resident believes in the terrible frequency of the dull, sodden-witted, debilitated opium smoker met with in print, nor have I found many Europeans who believe that they ever get the better of their opium smoking compradores in matters of business."

Another authority is Mr. John Crawfurd, F.R.S., a *savant* of high reputation, who had been Governor of the Straits Settlements, and who had resided and travelled for many years in those parts of the East and India. In 1856, he published a "Dictionary of the Indian Islands and Adjacent Countries." This is what he writes about opium :—

"Opium is at present largely consumed in the Malayan Islands, in China, in the Indo-Chinese countries, and in a few parts of Hindustan, much in the same way in which ardent spirits, malt liquor, and cider are consumed in Europe. Its deleterious character has been much insisted on, but, generally, by parties who have had no experience of its effects. Like any other narcotic, or stimulant, the habitual use of it is amenable to abuse, and as being more seductive than other stimulants, perhaps more so, but this is certainly the utmost that can be safely charged to it. Thousands consume it without any pernicious result, as thousands do wine and spirits, without any evil consequence. I know of no person of long experience and competent judgment who has not come to this common-sense conclusion."

He then proceeds to quote Dr. Oxley—

"A physician and naturalist of eminence, and who has had a larger experience than any man of Singapore, where there is the highest rate of the consumption of the drug."

Dr. Oxley wrote :—

"The inordinate use, or rather abuse, of the drug most decidedly does bring on early decrepitude, loss of appetite, and a morbid state of the secretions; but I have seen a man who has used the drug for fifty years in moderation, without any evil effects; and one man I recollect in Malacca who had so used it was upwards of eighty. Several in the habit of smoking it have assured me that, in moderation, it neither impaired the functions nor shortened life; at the same time, fully admitting the deleterious effects of too much."

Mr. Crawfurd sums up the question by this assertion :—

"Not the use, then, but the abuse of opium is prejudicial to health, but in this respect it does not materially differ from wine, distilled spirits, malt liquor, or hemp juice."

Dr. Eatwell, First Assistant Opium Examiner in the service of the Government, gave the following evidence :—

"Having passed three years in China, I may be allowed to state, as the result of my observation, and I can affirm thus far, that the effects of the abuse of the drug do not come very frequently under observation, and that when cases do occur, the habit is frequently found to have been induced by the presence of some painful chronic disease, to escape from the suffering of which the patient has fled to this resource. . . . As regards the effects of the habitual use of the drug on the mass of the people, I must affirm that no injurious results are visible. The people are generally a muscular and well-formed race, the labouring portion being capable of great and prolonged exertion under a fierce sun, in an unhealthy climate."

Dr. Eatwell concludes by observing that :—

"The proofs are still wanting to show that the moderate use of opium produces more pernicious effects upon the constitution than does the moderate use of spirituous liquors; whilst, at the same time, it is certain that the consequences of the abuse of the former are less appalling in their effect upon the victims, and less disastrous to society at large, than are the consequences of the abuse of the latter."

For many years previous to 1858, Dr. Sinibaldo de Mas had been the Envoy Extraordinary and Minister Plenipotentiary of the Court of Spain at Pekin. He had travelled much in China, India, Java, Borneo, and Malacca, and learned the Chinese language. In 1858 he published a book in French entitled "L'Angleterre, le Chine, et l'Inde," in which special reference is made to the opium question, with which he says he had made himself fully acquainted. I will quote only a few words:—

"It is a well known fact that in all these countries, notwithstanding their unwholesome climates, the opium-smoking Chinese are remarkably healthy and strong. These very opium smokers are employed as farm labourers, masons, and porters, enduring great fatigue and performing the most arduous labours; they have acquired such an excellent reputation as colonists that efforts have been made during the last few years to induce them to settle in Lima and Cuba. The per-centage of deaths among these people does not exceed the usual rate, and I must confess that having known numbers of Chinese emigrants in the various countries I have mentioned, I have never heard of a single death or any serious illness having been caused by opium smoking."

Baron Richthofen, the most experienced traveller who ever visited Sse-ch'uan, after noticing the extraordinary prevalence there of the habit of opium smoking, says:—

"In no other province except Hunan did I find the effects of the use of opium so little perceptible as in Sse-ch'uan."

Mr. Colman Baber, who knew more of that province and its people than any living Englishman, says:—

"Nowhere in China are the people so well off, or so hardy, and nowhere do they smoke so much opium."

Mr. W. Donald Spence, her Majesty's Consul at Tchang, in 1881, visited the capital of Sse-ch'uan. He reported the enormous extent of the cultivation of the poppy, and described whole districts as being one vast poppy field, and he thus speaks of the people:—

"I found the people of Sse-ch'uan stout, able-bodied men, better housed, clad, and fed, and healthier looking than the Chinese of the Lower Yang-tsze. I did not see amongst them more emaciated faces and wasted forms than disease causes in all lands. People with slow wasting diseases, such as consumption, are, if they smoke opium, apt to be classed amongst the 'ruined victims' of hasty observers; and amongst the cases of combined debility and opium smoking I saw, some were, by their own account, pseudo-victims of this type. There were some, too, whose health was completely sapped by smoking combined with other forms of sensual excess. And no doubt there were others weakened by excessive smoking simply, for excess in all things has its penalty. But the general health and well-being of the Sse-ch'uan community is remarkable; to their capacity for work and endurance of hardship, as well as to the material comforts of life they surround themselves with, all travellers bear enthusiastic testimony."

Time will not allow me to extend these quotations, although there is a mass of concurrent evidence on the subject. I will, however, add that of Sir Henry Pottinger, H.M.'s Governor-General and Minister Plenipotentiary in China, contained in a despatch written some sixty years ago, to the Foreign Office:—

"I cannot admit in any manner the idea adopted by many persons, that the introduction of opium into China is a source of unmitigated evil of every kind and a cause of misery. Personally, I have been unable to discover a single case of this kind, although I admit that, when abused, opium may become most hurtful. Besides, the same remark applies to every kind of enjoyment when carried to excess; but, from personal observations since my arrival in China; from information taken upon all points; and, lastly, from what the mandarins themselves say, I am convinced that the demoralisation and ruin which some persons attribute to the use of opium, arise more likely from imperfect knowledge of the subject and exaggeration, and that not one-hundredth part of the evil arises in China from opium smoking which one sees daily arising in England, as well as in India, from the use of ardent spirits, so largely taken in excess in those countries."

The picture drawn by the opponents of opium is that those who are in the habit of using it are a set of degraded, depraved, miserable wretches, enfeebled in mind and body, unfit for the active duties of life—thieves, vagabonds, and beggars. They do not admit —or, at any rate, never refer to the possibility of—the existence of moderate consumers, who, although they take their daily dose, are not only none the worse for it, but are actually benefited. The only exception which I have found is the Venerable Archdeacon Moule, who was for many years a missionary in China, and who has recently published his recollections of his life in that country. The Arch-

deacon is violently opposed to the opium trade, and has no words too bad for it; but he writes:—"Instances which have come under my notice make me think that opium smoking is already taking the place, not of abuse of alcohol (which it has hitherto held) in Chinese moral estimation, but of the use of alcohol; and that it is becoming possible to take the drug in moderation." He very sensibly adds that the Chinese have a fair right to say to the English people, "If you would prohibit our opium, abolish your alcohol."

But this ingenuous discovery of the possibility of the Chinese taking opium in moderation, as the mass of Englishmen take alcohol in moderation, has been known to every resident of China who has taken the trouble to inform himself of all the facts, and has not confined his attention to opium dens.

I will now examine the evidence as to the effect of opium consumption by the people of India. A Parliamentary Blue-book was published on this subject a few weeks ago. It contains the reply of the Government of India to a memorial of the Society for the Suppression of the Opium Trade, complaining of the increased consumption of the drug in India—a complaint which has been triumphantly disproved. This Blue-book contains the opinions of experienced officers engaged in the administration of the country, writing from their own personal knowledge, which it was a part of their duty to acquire, as to the effects of opium consumption on the people of India.

Now, let us see what these experienced gentlemen say. I will quote their evidence from every part of India.

The Province of Assam has a population of a little over 4,000,000, or about 2 per cent. of the whole population of British India. They consume 13 per cent. of the whole quantity of opium retailed by licensed vendors in British India. The following is the testimony of Mr. Driberg, Commissioner of Excise in Assam:—

"I am not prepared to admit that the present use of opium in Assam is a 'vice.' In most cases it is a necessity. When we first acquired Assam (I now speak of the Assam Valley) every villager grew his own opium, just as he now does his vegetables or his chillies for his curry. He had no tax to pay for his opium field, no restrictions placed on him. The former rulers recognised that a certain amount of the drug was necessary. Taking it broadly, and excluding tea gardens, the valley is inhabited by two classes; the Cacharies, Lalongs, Meches, and other aboriginal tribes, who reside on the higher submontake tracts, or along the high banks of the larger rivers, and the Hindus, the Kolitas, Koshes, Keots, and others who reside in the low-lying country, subject annually to inundation, and always damp. The former people do not use opium; they do not require it; but the lowlanders use it. They are the opium eaters of Assam. They live in a low, damp part of the country. Year after year parts of their villages are submerged and temporarily abandoned; and these people use opium to counteract the damp and malaria. They themselves say that they would die from fevers, if they did not use opium; and I have known medical men, who have had much experience of the province, hold the same view. These people are opium eaters, but not of the class described in the papers. They are good agriculturists, good subjects, and good fathers of families. They take their opium just as a good Englishman would take his peg. Of course, there are Assamese who take too much opium, just as there are Englishmen who take too much liquor; but, that opium eating is always a vice I am not prepared to admit, so far as Assamese are concerned; and, that it is increasing, I deny, and the statement I have referred to proves my view. In the Surma Valley, little opium is consumed. The people there use ganja, rather than opium; and even there, the consumption of this drug is smaller now than it was in 1874-75, and the duty is higher."

The views of Sir Charles Elliott, Lieutenant-Governor of Bengal, an officer of long and wide experience in India, will be gathered from the following paragraph of his report to he Government of India:—

"As to the proposal to limit the possession of opium to one tolah instead of five, its effect on the ordinary consumer of opium would be undesirable. A quarter of a tolah is a common, perhaps the commonest, dose taken daily by those who are addicted to the use of opium, and it is within Sir Charles Elliott's personal knowledge and experience that this quantity is taken by innumerable persons in all parts of India, from Rajputana and the Punjab to Assam, without any injury or physical deterioration; that heavy tasks are easily performed under the stimulus it supplies; and that the prevalent belief is that the stimulus is wholesome, even in a dry climate, and is especially beneficial in moist and marshy countries like Eastern Bengal. The consumer of such a dose can now procure his supply for twenty days by one visit to an opium shop; if the limit were reduced to one tolah, he would require to visit the shop every four days—an annoyance which there is no reason for imposing upon him, and the imposition of which would lead to increased smuggling and to breaches of the law."

The opium agent of Behar writes:—

"We have to consider the consumers of opium in the malarious alluvial tracts which form a great proportion of the area of these provinces. The use of

opium by these people is not so much a vice as a necessity. Their vegetable diet would not keep them alive without stimulants, and I doubt whether it would be for their benefit to stop their opium and drive them to ganja or spirits. On the comparatively dry laterite soil the people are spirit drinkers. On the alluvial mud they either use opium or the far more deleterious ganja.* I do not believe that the prevention of the cultivation of the poppy in British India would cut off the supply of a drug which bears so high a value as opium, which the people believe to be so necessary to them, and which from its small bulk is, if the smell is disguised, very easily smuggled. I also doubt whether there is any equally efficient febrifuge within the reach of the people, and whether their health would not suffer greatly if they could not procure opium. It does not appear to produce such insanity as ganja does, and, where people are as well fed as the Mahomedan ryots of Eastern Bengal, I am informed that opium smoking does not injure them. It is said to be opium smoking on insufficient food that affects the health.

"In conclusion, I may say that I believe there has been much exaggeration as to the scenes of intoxication to be witnessed in the chandu and madak shops. As I have already said, there is none in the retail opium shops. I have visited shops in which more than a score of persons have been smoking chandu or madak without seeing any person lying intoxicated, or unable to answer my questions intelligently. I have also, however, seen persons in other shops lying asleep, and presumably intoxicated, but not many. It is, I believe, usual for the smokers of chandu, the Chinese preparation of opium, to sleep, presumably intoxicated, before leaving the premises; but in the madak shops this is by no means always the case, and I have seen many get up and go away quietly from the shop after smoking the drug. They have told me that they have no desire to sleep after it."

The Commissioner of Excise in the Central Provinces writes:—

"The eating of opium (as distinguished from smoking it) in moderate quantities, though generally held in disrepute and regarded as a vice by those who do not indulge in it, is not considered to be always harmful. Indeed, the current belief is that in certain localities and for certain ages and constitutions its use may be actually beneficial and conducive to health and longevity."

The Financial Commissioner of Burma says:—

"The Chinese at Bhamo and also in Mergui assured me that they could not exist in malarious countries, such as those in which the jade and amber mines and the tin mines are situated, without opium. As far as I know the use of opium is universal amongst the Chinese and hill tribes in feverish tracts. I believe that they seldom abuse the use of the drug, and I have every reason to suppose that its use is beneficial under certain conditions."

Sir Charles Aitchison, who was Chief Commissioner of Burma, says:—

"There are large numbers of the non-Burmese community, constituting perhaps the most thriving and industrious section of the population, to whom the drug is a necessity of life, and by whom it is rarely abused."

Mr. Copleston, the Commissioner of Excise in Burma, gives similar testimony. He says:—

"The use of opium by the Chinese and natives of Madras, who consume a considerable quantity, is not known or believed to work special evil either to individuals or to society, the reason being that these people do not abandon labour and active pursuits in order to eat or smoke opium, and its bad effects are therefore thrown off. The Chinese especially are well nourished, and this fact, too, appears to be an important one. In this case opium may almost be called a legitimate luxury."

It is true that the authorities in Burma seem to have arrived at the strange conclusion that opium is a benefit to every one in that country, except the Burmese themselves, to whom it is said to be an unmitigated evil. No definite evidence of this is adduced. It seems to be based on the expressed opinion of certain Burmese gentlemen who do not use the drug.

The Government of Madras reports the result of the visit by an official to most of the "opium dens" in the town of Madras:—

"1. Most of the smoking dens were visited, and in each from 10 to 20 smokers were seen. They were of all ages—from 20 to 60 years of age—and comprised both Muhammadans and Hindus. Several professions were represented—jutka drivers, native doctors, musicians, professional beggars, butchers, sweetmeat sellers, and petty shop-keepers. Some were smokers of a few months, some of 20 and 30 years' standing.

"2. In most cases the smokers left immediately after they had finished their smoke. They purchased 8 pies to 2 annas and 6 pies worth each. Each smoker usually brought some sweetmeats or sugarcane with him, and ate or chewed it while smoking. This, it was said, was done as the opium produced a bitter taste in the mouth.

"3. To see any smoker more affected than a man who had taken his usual glass of liquor was very rare, and in such cases it was said that the man had either taken his smoke out of time or had smoked more than he was used to.

"4. No women or children were seen in the dens, and it was stated that they do not frequent them.

"5. Cases of emaciation from the effects of opium-smoking were not seen. Many of the old smokers

* Hemp.

seen were, on the contrary, very robust and well-conditioned; notably among these might be mentioned the keeper of one of the dens, a Chinaman, who is reported to have smoked for over 30 years, and who is now over 50 years of age; a vendor of country spirits, a smoker for over 20 years; and a Muhammaden Hakim of about 45, who has smoked for over 10 years.

"6. Most of those spoken to admitted that the habit once contracted was difficult to give up, but they said that it did them no more harm than the workman's glass of liquor did, if they did not exceed their usual quantity.

"7. Several complaints were made that the opium was now so dear, that what a few years ago cost 3 or 4 pies could not be purchased for 1 anna."

The report from the Government of the North-West Provinces does not enter into the question of the effect of consumption of opium on the people. The poppy is largely cultivated in these Provinces, and the facilities for the illicit use of the drug are naturally great. The absence of any mention in the Government Reports of any marked evil effects on the population is, at any rate, negative evidence that no glaring abuses exist.

The Government of the Punjab reports:—

"The ratio of consumption of opium to population is not so high as to be a cause of anxiety in regard to the health and morals of the people. In the few tracts where the habit may be said to be general among certain classes of the population, it is of old standing, and does not seem to do so much harm as might be expected. The people, on the contrary, assert that they find it a protection against fever."

The Commissioner of Excise in that province writes:—

"The Government of India requests that the general questions raised may be discussed as far as they affect the Punjab, and in replying to the Government of India it should, I think, be forcibly pointed out that, apart from financial considerations, any attempt to prohibit the sale of opium, except for medicinal purposes, would in this province be most unpopular, and consequently politically inexpedient; while, if the poppy were grown without restriction, and the sale of opium were allowed free, the consumption of opium and its preparations would inevitably increase. Sikhs, Hindus, and Muhammadans alike eat opium, and at present the residents in the Phulkian States are the largest consumers.

"The memorialists themselves admit that in malarious tracts opium is useful as a prophylactic, and I think that the opportunity afforded by the presentation of this memorial should be taken to state clearly that the poppy has been cultivated and opium eaten in the Punjab from a period antecedent to British rule: that the drug, when taken in this form in moderation, is not believed to be necessarily prejudicial; and that, although indulgence in the habit may legitimately be restricted by taxation, and thereby made a source of revenue to the State, prohibition and unrestricted consumption are alike out the question."

The Collector of Nasik, in the Bombay Presidency, writes:—

"My own opinion is—and it is formed after 23 years' service actually among the people and in nearly every part of the Bombay Presidency and of the Mysore Province—

"1. That opium smoking or eating, as practised by the vast majority of people who use the drug, is not carried to excess.

"2. That the moderate consumption of opium is no more harmful than the moderate consumption of liquor, and in many cases, like the moderate consumption of liquor, is distinctly beneficial.

"3. That the increased revenue from opium is due (*a*) to the more effectual steps taken to prevent smuggling, (*b*) to the increasing population, and (*c*) to the increasing prosperity of the people, which gives them more money to spend on luxuries.

"4. That the 'opium sot' is a much less harmful person to his family and to his neighbours, and the community generally, than the drunkard; and

"5. That Government, even if it tried, could no more prevent the consumption of opium than the consumption of drink. It would be useless to attempt to achieve either end: it would be worse than useless. It would, in my opinion, be a blunder, for I can see no weight in the reasoning that would prevent the vast bulk of the population indulging moderately in the opium luxury, simply because a very small minority harm themselves by indulging in it to excess.

"As regards those parts of India which I know well, and those alone, it is a gratuitous assumption that opium smoking causes 'widespread misery and demoralisation,' and so also is it that 'the British connection with the opium trade' is a 'serious hindrance to missionary work.' Apart from the fact that the Government of India has nothing to do with missionary work, I have never once in 23 years heard a single missionary—and I have met dozens—specially refer to or quote the opium trade as interfering with his endeavours. The proposition is true in the abstract, no doubt, but in the same manner that the abstract proposition is true that the existence of public houses in the slums of London interferes with Christian effort there."

The Collector of Khandesh, also in the Bombay Presidency, who has served many years in that district, expresses his disbelief that the consumption of opium is having any bad effects on the people of agricultural districts. He writes:—

"Reading the extracts printed in the selections

forwarded by the Government of India, it strikes me that the gentleman who penned the highly coloured accounts of opium dens must have been shown the worst haunts in large towns, and that they and those who think with them inveigh against the use of opium much as teetotallers at home attack the use of spirits and beer and wine, because of the evils of the gin palaces of our great cities. I am not prepared to admit that the use of opium in moderation is more harmful than the use of whisky. Every one who has served in Gujarat must have seen many sturdy Rajputs who took their opium regularly and were none the worse for it."

Mr. Campbell, Collector of Bombay, after quoting the accounts of opium dens given by the Anti-Opium Society, goes on to say :—

"In my judgment, the picture which these accounts give of the opium smokers is overdrawn and misleading. The statement that in Bombay houses children smoke, is supported by so much precision and detail as to make it difficult to suppose the writer was mistaken. At the same time, cases of allowing children to smoke must be extremely rare. I have never seen a child smoking, or who had smoked, or who was intended to smoke. I have never seen a child in a smoking house, except the child of one of the shopmen, who professed to be, and was, I believe, aghast at the idea of allowing his child to smoke. I have not heard, either from inspectors or smokers, of the case of a child being allowed to smoke; on the contrary, after special inquiry, the Chief Inspector assures me that such cases are unknown. As to the men smokers, and the effect of smoking on their character, appearance, and health, the descriptions under review seems to me misleading. I have no fault to find with the general description of a Bombay chandul house, given at page 9 of the reprint :—'A dirty, dilapidated, nondescript shop, with its shutters up. . . . . Raised platforms, with some hundred recumbent and semi-recumbent figures, all men, except three women and a few lads. . . . . Groups of smokers, some half lying, half sitting, others curled up, or reclining at full length.' Except that, so far as I have seen or can learn, no youths under 18 attend these smoking-houses, this description seems to me accurate. The Poonah description is also moderate :—' A low-roofed room, with 25 to 30 persons, in groups of five or six round each lamp, most of them intent on their pipes, a few in a semi - conscious state.' On the other hand, I have seen nothing to justify the following passages :—' Human swine of both sexes . . . . most immodest attitudes . . . . handsome young women sprawling on the senseless bodies of men.' Such sights, I believe, are not to found in Bombay smoking houses. In a room of 40 or 50 smokers all but three or four are awake. The bulk of them have done a hard day's work. They are tired and indolent. In opium-smoking houses assaults or acts of violence are almost unknown. Of the smokers very few are unable to answer questions clearly and readily. Even those asleep awake when lightly shaken. Even when suddenly aroused they can at once tell their name and calling. 'If you had to go out now and work, could you go?' Almost always the answer is 'Yes, we could.' Again, as to the effect of opium smoking on character. It is true a share of the smokers are beggars, and a share of them are bad characters. It is true the houses are watched by the police, for thieves meet in them and scheme crimes. Still, are all or nearly all the smokers ne'er-do-wells? Not nearly all. So far as I have seen, a Bombay opium-smoking house is much like Dr. Morison's description of a Bengal smoking house :—Almost all the smokers are of the labouring classes, tailors, day labourers, and one or two shopkeepers.' So far as I could judge by questioning the smokers in Bombay smoking houses, about two-thirds are regular working craftsmen and labourers. I asked the Assistant Collector to frame a separate estimate. His estimate was :—' At the fewest 70 per cent. regular craftsmen and labourers; at the most 20 per cent. beggars, and 10 per cent. bad characters.' I made a further personal test in three houses taken at random. The result was :—In one house of 11 smokers all were craftsmen in regular work; in a second house of 25 smokers all were craftsmen in work; in a third house of 47 smokers one was a woman, 9 were beggars, the rest were craftsmen and labourers. I have made the chief inspector take a similar test in 14 more houses. The result is, of 227 smokers 188 are workers, 38 are beggars, and one is a thief. It is probable that some among the workers are bad characters. Still care was taken to ascertain that in most cases the smokers are actually employed on the work they named. The estimate that two-thirds of the whole smokers are able to do and do regular work as labourers, weavers, embroiderers, sailors, drivers, cartmen, blacksmiths, mill hands, fitters, barbers, and also as small traders and shop-keepers, sellers of firewood, fish, tea, coffee, tobacco, and cloth seems well within the mark.

"Similarly, as regards the effect of the smoking on the health and the appearance of the smokers, the descriptions seem to me overdrawn and misleading. 'Of horrible destructions of God's image more terrible than delirium tremens, idiocy, or lunacy,' I have seen none. Of the starved and emaciated shrivelled warnings I have seen surprisingly few. The bulk of the men, I should say over two-thirds, though smokers of 8, 12, 20, and in one case of 40 years' standing, were in body and face to look at well nourished and healthy. To many of them I, in surprise, asked the question which Dr. Morison asked in Bengal :—You have smoked four or five years and are stout and strong. How is this? The explanation in Bombay is the same as the explanation in Bengal :—Smoking does not injure those who are well fed as it injured the starving. On the point of appearance and harm to health I checked my first impression by my assistant's experience. His answer

was:—'Almost none, except the old and the beggars, not more than 10 per cent. in all are emaciated.' made a personal test in three houses. In one of 11 smokers all seemed healthy and well nourished; in a second of 25 smokers, one old man was emaciated; in a third of 47, though the beggars looked dissipated, none were notably withered or broken. In the 14 houses specially tested by the chief inspector, 10 were found emaciated or slightly withered. In almost every case the emaciated and withered were over 50 years of age. So far as I can judge, the assistant collector's estimate is correct, that, except some of the old and some beggars, very few opium smokers are notably withered or emaciated."

The whole of Mr. Campbell's report deserves attentive perusal.

The last report I shall quote is that of the Commissioner in Sind. He says:—

"The society assumes that the consumption of opium, even in a moderate degree, is detrimental to man both physically and mentally. It is far from certain, however, that this assumption is correct, and we have the evidence afforded by whole tribes who have habitually, from generation to generation, taken opium. As instances may be taken the Rajputs and Bhils. Their energy, endurance, and bravery cannot be said to have been affected by their addiction to opium. Throughout the country one meets with people who take opium in moderation, and for much the same purpose and with much the same result as the English gentleman of the present day takes his wine."

Such is the evidence of persons who are in the best position to know the facts. I could add much more to the same effect. It completely establishes the contention that it is the abuse and not the use of opium which is harmful, that the moderate use is the rule, and that excess is the exception.

I now come to the proposals of the "Society for the Suppression of the Opium Trade," as to the actual practical steps to be taken to arrive at their object. I find them in a pamphlet published by the Secretary of that ociety in 1890. The first two and the fourth are thus stated:—

1. That the Bengal system of licensing the growth of the poppy and of manfacturing opium be at once stopped, except so far as may be needful for legitimate medical use.

2. That the necessary measures be at once taken, by raising the tax or otherwise, to prevent any extension of the cultivation of the poppy in Malwa, so as to compensate for the diminution of the supply from Bengal.

4. That the retail sale of opium throughout India be limited by measures having the same object as the provisions of the Pharmacy Act in Great Britain, namely, to restrict the sale to that which is required for medical use alone.

It will be observed that nothing is said of the poppy cultivation in the Punjab; perhaps the society are not aware of its existence. I assume that they would propose to stop that also. Otherwise smuggling from that province would assume enormous dimensions. Then, I would ask, what is meant by "legitimate medical use?" When we find whole tribes of people, living in malarious and fever-stricken tracts, using the opium daily as a prophylactic, is that a legitimate medical use? Or is it intended that no one shall be permitted to purchase opium except under the written authority of a duly certificated member of the medical profession? How many of the opium consumers in India are within reach of an English doctor? Could you trust the native Baids Hakims, and Pansáris, the doctors and druggists of the country, with this power? Anybody with any knowledge of India would laugh at such an idea. How then are you to meet this great practical difficulty?

It may be possible in British territory, by the exercise of despotic power, to prevent the poppy being grown, but what are "the necessary measures" so vaguely suggested for preventing its extension in the native States? Every tyro in Excise or Customs administration knows that the power to raise duties on an article in large demand is limited by the means of preventing its illicit production and sale, and that if you increase the profits of smuggling, you will proportionately have to increase your preventive measures. Unless British officers and establishments were appointed to overrun the native States, and to interfere with the agricultural operations of the people, the cessation of the growth of the poppy in British territory would infallibly lead to an enormous extension of the cultivation in native States. The export thence of opium could only be prevented by Customs barriers and patrols round Rajputana and Central India, involving a line between 2,000 and 3,000 miles in length, and heavy expenditure on the establishments. How would the native States concerned regard such measures? I have no hesitation in saying that the discontent occasioned not only in those States, but amongst our own people, including the Sikhs—from whom the flower of our native army is recruited—would constitute a very serious political danger.

I was myself in charge of a Customs' line,

2,500 miles in length, the greater part of which was maintained to keep salt produced in native States from entering British territory without the payment of a heavy duty. I am well acquainted with the evils of that barbarous system, the destruction of which I was one of the first to advocate, and spared no efforts to accomplish. It was achieved by entering into treaties with the States possessing salt sources, under which British establishments are permitted to supervise their salt works, and tax the produce before it leaves them. But this could be accomplished only by paying the States concerned compensation, in the shape of lump sums of money and annual assignments, which are met from the taxation of the salt consumed by their people. But how are you to conciliate the native States for interference in their poppy cultivation? Will the people of India, or the people of this country, submit to be taxed in order to compensate these native States, and to reconcile their rulers to an army of British preventive officers scattered over their territories? And if you reconcile the rulers by paying them, how are you to conciliate their people, who have been accustomed for centuries to the unrestricted use of opium? Without such preventive measures British India will be supplied with the Malwa drug, which, from its great value in a small bulk, is comparatively easy to smuggle. And these preventive measures must be of the strictest kind, involving the searching of the persons and goods of all travellers, and domiciliary visits, to detect the carriage, and prevent the storing of the drug.

I now come to the third proposal of the Society for the Suppression of the Opium Trade. It is as follows:—

3. That the Chinese Government be approached with proposals for diminishing the export of Malwa opium, simultaneously with the suppression of the growth of the poppy throughout China.

I do not wish to use disrespectful language, but I can hardly speak of such a proposal with gravity. The Chinese Government, who have for centuries fulminated futile edicts, threatening the heaviest pains and penalties against the growth of the poppy and the use of opium, but whose officials have never had the will or the power to enforce them, and who are known to connive at the open and unconcealed infringement of the law, are to be "approached" by the British Government, with this request:—"Now that we are doing our best to deprive you of Indian opium, which your people for centuries have demanded on account of its superior quality; now that we have, by our restrictive measures, encouraged the growth of the poppy in China, and the home production of an inferior article, to such an extent that whole provinces are covered with its cultivation; now that we are mulcting your import customs revenue of about £2,000,000 sterling a year: will you be good enough at once to stop the cultivation in China, and deprive your people of an article which we believe to be an unmitigated evil; although there is a large body of Englishmen, who, from personal experience, have testified that it is harmless to the great mass, who are moderate consumers?" How would such a request be met? If the solemn and self-possessed Chinaman has any sense of humour, by inextinguishable laughter.

But why should our philanthropy stop here? I read a statement a short time ago in a paper called the *Foochow Echo*, to the effect that some of the Chinese are planting poppy in the place of tea. If they meet with success, it is said others will follow their example and give up tea altogether. It is the competition of Indian tea in the markets of Enrope which has lowered the profits on China tea. Let us trust that India will not be asked by the Anti-Opium Society to give up producing tea, in order to prevent the Chinese turning their tea gardens into poppy fields. And what of the hypocrisy of a people who not only derive nearly half of their public revenue from the consumption of alcohol and tobacco, but support from this consumption an enormous commercial industry of brewers, distillers, hop and barley growers, merchants, importers, agents, and vendors, what of their hypocrisy in asking India and China to forego the profit derived from the opium trade?

I am aware that many of the opponents of opium would also prohit the use of alcoholic drinks in the United Kingdom, but before "approaching" China, let the people of this country set the example, and make the liquor traffic, except for purely medicinal purposes, illegal; let them forbid by law the cultivation of the hop plant, and the growth of barley for distillation or malting; let them forbid the import of wine and spirits from the Continent of Europe and elsewhere, and then they will be in a position to "approach" China with a prayer for the destruction of the poppy cultivation and the trade in opium.

It has been suggested that if the culture of poppy were prohibited other crops would take

its place and thus supply a great part of the loss. But would the farmers of Kent be satisfied if the temperance party were to say to them, "We will pass a law to prohibit your cultivating hops. You can, however, grow potatoes or gooseberries instead?"

It is true that a more moderate party in this country does not go the length of prohibiting the cultivation of the poppy and the manufacture of opium in Bengal. They are shocked at the direct management by the Government of these industries. No question has been more fully discussed in India than this, there are volumes of correspondence relating to it, but the upshot of all these discussions has invariably been the recognition of the fact that, under any other system, the cultivation could not be so well restricted, that smuggling would be more rife, that the cultivators would be brought under influences of speculators, from which they are at present guarded, and that whatever evils now exist would be largely increased. The Society for the Suppression of the Opium Trade recognise this, and in the pamphlet I have quoted, declare that the proposal is entirely inadequate, and that their demand is nothing short of absolute prohibition.

India has had the advantage of drawing from England, for more than 100 years, a number of upright, honest, and able administrators. It is remarkable that there is not a single instance of an Englishman who has been directly responsible for the well-being of India, and who has had an important voice in its administration, who has ever suggested the prohibition of the cultivation of the poppy. That has been left for a party of irresponsible persons in this country, whose want of knowledge is patent to everyone who has studied the question on the spot.

I will give one recent and striking instance. There is internal evidence that no one who joined in the memorial of the Society for the Suppression of the Opium Trade, of the 30th July, 1890, which is published in the recent Blue-book on the consumption of opium in India, had the most elementary knowledge of India, or, if there were such a person, he could not have read the memorial. In it Lucknow is described as being in the Punjab, and Lahore as being in the North-Western Provinces! This blunder is as stupendous as would be that of persons memorialising for the suppression of alcohol in Europe, who should place Paris in Scotland and Dublin in Holland.

There have just come into my hands two articles from native newspapers, published, one in Calcutta, the other in Bombay. The Calcutta paper is called *Bangavasi*. It has the largest circulation of any of the Bengal papers, being about 20,000. The following is a translation of an article which appeared in that paper on the 30th January last:—

"What harm does Government's opium business do to us? Does Government press us to eat the drug? Or is it that the sight of an opium shop creates such a craving for the article that one cannot help eating it? Now, the opium shops, as such, possess no attractions for the people, their existence merely making it easy for habitual opium eaters to buy it for their use. We believe that most of those who use opium suffer from some disease, and use it medicinally. Opium is a medicine in gout and in all diseases of the bowels and kidneys. That opium used in old age prolongs life is also a common belief. For all these reasons many people use the drug in large or small doses, and gradually become confirmed opium-eaters. It is not the sight or appearance of the opium shops, which by the way is the most revolting possible, that attracts men thereto. Nor is it the case that men eat opium for the purpose of showing their loyalty to Government, which trades in that article. Nor, again, do people go to the opium shops from the consideration that by buying opium they would help to rescue Government from its financial embarrassment. Habitual opium eaters can do without their daily bread rather than forego their regulation dose of the drug. Again opium is largely used as a medicine in all systems of the medical treatment—allopathic, homœpathic, ayurvedik. People resort to the opium shops for all these purposes, and not a man is attracted to them by their mere appearance, as is the case with liquor shops. An opium shop has nothing of the wine shop's attractive glitter of glass and beauty of label. Nor does a dose of opium produce that exhilaration of spirits which makes the wine-bibber sing and dance in joy. What attractions then does an opium shop possess for the public? We do not really see that an opium shop licensed by Government can hold out any temptations to men. Its appearance is rather calculated to repel men from it. If it had been otherwise, if the mere sight of an opium shop had been enough to attract customers, we would have freely condemned the opium business of the Government.

"A person under the influence of opium does not become querulous or boisterous. Nor does a habitual opium eater bring beggary and destitution upon himself and family, and die an untimely death. The number of untimely deaths among opium eaters is very few. If it had been otherwise, we should have been the first to condemn the opium trade, and ask Government to discontinue the sinful business.

"It is true that opium is used for committing suicide. But those that will commit suicide will

commit it even if they do not get opium for the purpose. Government does not trade in arsenic or ropes, and yet many people put an end to their lives by swallowing the former or drawing the latter round their necks. If Government discontinues its opium business, others will take it up, and there will still be cases of suicide from opium-poisoning. We are, therefore, really unable to understand what harm is done by the Government's trade in raw opium.

"These remarks apply in some measure to the different preparations of opium, and particularly to guli. The guli shops present a most repulsive appearance. As it is, however, desirable on various grounds that such shops should cease to exist, the writer would not object to Government's directing their abolition.

"What good will the changes now proposed to be made in connection with Government's opium business do to the country? And is it possible to do the amount of good that is expected? We do not see that the Government's opium business does any harm to anybody. Opium cultivation will not cease even if Government gives up the business. Nor is it desired that that cultivation should cease. Now, suppose Government gives up the business, and somebody finds himself at liberty to grow and sell and purchase opium. Suppose the opium shops, flourishing as before, with this difference only, that the signboards put up in front of the shops no longer contain the words 'By order of Government.' The accounts are made up, and they disclose a large deficit in the finances. Government, however, must meet its regular expenditure, and that means that the people must raise the money from other sources. It is thus clear that the people will gain nothing by the abolition of the Government's trade in opium."

The *Bombay Samâchâr*, a Guzerâti paper, which has the largest daily circulation in Bombay, has the following article on the 19th February last:—

"The opium agitators in England seem to be insensible to the great pecuniary loss that would be inflicted on the people of India by a prohibition against the production of opium in India and its export to China. To the ranks of the opium agitators in England an addition has now been made in the person of Miss Sundrâbâi Powâr, an Indian lady. In an address recently delivered by her at Sheffield, Miss Powâr asserted that the use of opium had created great mischief in India, and that as she could not quietly bear this sight she had gone to England to plead for the abolition of the opium monopoly. It is not known in Bombay who Miss Powâr is, and what she did while she was in India to stop the alleged evil effects of the consumption of this drug. Miss Powâr accuses the Government of India of having encouraged the opium trade in the interests revenue, but no mischief whatever, we assert, has been created in India by the consumption of opium. On the other hand, considerable evil has been caused by a free use of country and Europe spirits, particularly among the educated persons, and the Government of India is very particular about increasing its revenue from this source. Miss Powâr ought to bear in mind that there is more need for checking the consumption of spirituous drinks than the use of opium."

Mr. Samuel Laing, when Finance Minister of India in 1862, made the following remarks:—

"This much seems certain in speculating on the probable continuance of a demand for opium in China. Every civilised or semi-civilised race of mankind seems to affect some peculiar form of nervous stimulant, and as the natives of Northern Europe take to alcohol, so the Chinese take to opium. Possibly, in each case, the craving is for something to supply an innate want. The Englishman, the Dane, the German, and the Russian resort to that the specific effect of which is to raise the spirits and produce temporary exhilaration. The Chinese, whose greatest deficiency, as shown by the whole history, religion, and literature of the race, is in the imaginative faculties, resorts to that which stimulates the imagination, and makes his sluggish brain see visions and dream dreams. Be this as it may, the fact is certain that, under all circumstances and in all climates, as the Englishman is a drinker of beer, so is the Chinaman a smoker of opium. We have, at the bottom of our opium revenue, one of the great natural instincts of a large population, upon which English Chancellors of the Exchequer confidently rely for half their revenue."

I have not dealt with the comparative physiological effects produced by the use of alcohol and opium, and other drugs; but I hope some of the more scientific gentlemen here this evening will speak on this point. From all I have learnt on the subject, I believe that the excess of the use of alcohol is far more destructive to the human frame than that of opium, for one attacks the tissues and the other produces only functional derangement. If the people of India are deprived of opium, the consumers of it will infallibly have recourse to alcohol or to hemp, which grows wild in many parts of the country, and the effects of which are, when taken in excess, maddening.

Indeed much of the evil character which is given to opium is due to its being frequently adulterated with or used with hemp. The *hashish*, from which the English word "assassin" is derived, and the *bang*, which is notoriously the stimulant used by fanatics in India when intent on reckless slaughter, are nothing but hemp. It would be beyond the power even of Parliament to eradicate hemp from India.

From the mass of evidence to be found in the writings of members of the medical profession who have acquired their experience amongst the people who use opium as a stimulant, I will quote a few passages.

Dr. W. B. O'Shaugnessy, in the "Bengal Dispensatory," 1841, writes :—

"The longevity of opium-eaters is, in many parts of the East, of proverbial notoriety. . . . When the habit is but moderately followed, it appears to occasion no greater evil than the proportionate indulgence in wine or other spirituous liquors."

Dr. D. McPherson, in his book on "The War in China," 1843, has the following passage :—

"From the earliest periods in every nation, and among every people, we find some description of stimulus in common use among them; and were we to be led away by the popular opinion that the habitual use of opium injures the health and shortens life, we should expect to find the Chinese a shrivelled, and emaciated, and idiotic race. On the contrary, although the habit of opium smoking is universal amongst the rich and poor, we find them to be a powerful, muscular, and athletic people, and the lower orders more intelligent and far superior in mental acquirements to those of corresponding rank in our own country. The Chinese themselves affirm that the use of the drug acts as a preventive against disease, and, in this opinion, when smoked in moderation, I am inclined in part to agree with them. The particles, by their direct and topical influence on the nerves of the lungs, which carry the impressions they receive to the heart, brain, and spinal cord, and through them to all parts of the body, may thus, to a certain extent, guard the system against disease, and, by its tonic influence, strengthen the several organs. This opinion gains strength, when we call to mind that a peculiar active principle in opium—the narcotine—has of late been employed, with considerable success, in Bengal, as a substitute for quinine. It may also be mentioned that, at the time fevers prevailed so extensively among our troops at Hong-Kong, but comparatively few of the Chinese suffered, though exposed throughout to the same exciting causes."

Dr. Cornish, Sanitary Commissioner for Madras, drew the attention of the Government to the great consumption of opium in the Godavery district. An investigation was ordered, and the officer who reported on it, in 1874, came to the following conclusion :—

"I believe that the extensive use of opium in this district is due to the extensive prevalence of fever, and that if fever could be checked, so would the use of the drug. Conversely, I think it unadvisable to attempt arbitrarily to stop its consumption at resent."

Dr. Vincent Richards, who was in medical charge of Balasor, in Orissa, where opium-eating is very common, made very careful inquiries into the matter, and collected elaborate statistics connected with it. He wrote, in 1877 :—

"I estimated that about one in every twelve or fourteen of the adult population used the drug, and I believe the habit is somewhat increasing. The greatly increased consumption of the drug dates from the famine year 1866, when it was, if I remember rightly, nearly trebled; since when it has, I believe, pretty steadily increased. This is not the result of a growing abuse of the drug by individual consumers, but of a more extended use of it amongst the general population. There can be no doubt that opium-eating was greatly resorted to in the famine year, because it mitigated the sufferings arising from hunger and sickness, and enabled the poor people to live on less food. . . . . Opium-eating—at any rate at Balasor—does not conduce to either crime or insanity, since the inhabitants are a particularly law-abiding race, and the insanes are only ·0069 per cent. of the population. . . . . The general conclusions I arrive at are—1st, that opium is taken habitually by about 2 to 10 per cent. of the adult population of Balasor, and that the average daily allowance for a man is 7 grains, and for a woman 5 grains; 2nd, that moderation is the rule; 3rd, that moderate doses include from 2 to 16 grains *per diem*, according to circumstances; 4th, that opium-eating is much more common in unhealthy localities than in healthy ones, even though they are situated in the same district; 5th, that the drug may be, and is sometimes, taken in very large doses—30 grains and upwards—without producing any very serious ill-effect, much depending on the constitution of the individual, and his habituation to its use; 6th, that whatever the effects of the excessive use of the drug may be, when taken in moderation it is positively beneficial, where such diseases as fever, elephantiasis, rheumatism, &c., are prevalent, and when food is scarce; 7th, that the effects of even the excessive use of opium are harmless, both to the individual and to society, compared with those of the excessive use of alcohol."

The views of Sir William J. Moore, who had an extended experience in Rajputana, and was afterwards Surgeon-General with the Government of Bombay, are well known, and I hope that he will again state them on this occasion. They fully accord with those I have already quoted. There are literally volumes of evidence of a similar character.

We have, then, a great *consensus* of opinion arrived at by a number of independent persons of high character and reputation; gentlemen of ability and integrity, who have attained to responsible positions, in which they have had the best opportunities of ascertaining the truth;

whose duty it has been to state the truth; and who have had no personal interest in perverting it. They deliberately declare that the daily use of opium in moderation is not only harmless, but of positive benefit, and frequently even a necessity of life; that this moderate use is the rule, and that excess is the exception. On the other hand, we are told by a society, chiefly consisting of Englishmen who have no personal knowledge of the facts, that all this evidence goes for nothing, and that the use of opium, except for strictly medicinal purposes, is an unmitigated evil, and ruins every one who habitually has resort to it. If we accept this view, which differentiates opium from every other stimulant used by great masses of people, we must believe that all those experienced persons who have testified to the direct contrary are either grossly incapable or grossly dishonest. It is no use mincing words; a man must be one or the other who, having lived for years amongst an opium-consuming people, and having made a careful study of the effects of the habit, deliberately declares as the result of his inquiries that which is untrue. And on what is the opposition based? Chiefly on the statements of English missionaries in China. I respect the sincerity and the high and noble purposes of these gentlemen, but, as the French phrase it, they have the defects of their qualities. They are filled with a burning zeal to better the physical and spiritual condition of the poor and miserable Chinese with whom they are brought into contact. They find numerous instances of the degradation which is produced by the abuse of opium in the prosecution of the objects for which they are struggling. They are met by the astute Chinaman with the argument that opium is an evil thing, and that the English who import it into China are out of Court when advocating morality. They fall into the trap, and jump to the conclusion that it is the opium trade which prevents their making faster progress in the evangelisation of China. Only one side of the question is brought prominently to their notice, and that the worst side. Their experience is almost entirely confined to towns on the sea coast. They knew little or nothing of the millions of the healthy, industrious population in the interior of the country to whom the use of opium is as common, as moderate, and as beneficial as that of beer is to the people of England.

In conclusion, I would say to the Society for the Suppression of the Opium Trade—You may make this a party question; you may win votes relying on the uninstructed philanthropy of your fellow countrymen; you may, through Parliament, use the despotic power of the British Government to destroy one of the most valuable products of India, and subject the people to new taxation in order to supply the loss of revenue now paid chiefly by the Chinese; you may deprive hundreds of thousands of her Majesty's Indian subjects of a prophylactic which enables them to resist fatigue, to sustain privation, and to save life; you may thereby increase suffering, sickness, and mortality; you may cover India with an army of preventive officers to watch another army of smugglers, created to satisfy a natural demand of which you have suppressed the legitimate supply; you may harass the people by personal searches and domiciliary visits; you may thus create discontent amongst our native subjects, and disaffection in the best forces of our native army; you may, by unwarranted and unprecedented interference in their internal administration, and, owing to the pecuniary losses both rulers and subjects will sustain, disgust and alienate the native States of Central India and Rajputana, our bravest and most loyal allies; you may drive the consumers of opium to alcohol and hemp; you may do all this, but you will never persuade the Chinese to follow in your footsteps, and abandon the ever-increasing culture of the poppy. In short, you may inflict on India a cruel injury, the extent and the consequences of which you are incapable of calculating; but you will fail in any way to benefit China, unless you count it a benefit greatly to extend the cultivation of the poppy, and the manufacture of opium within her borders.

DISCUSSION.

Mr. SAMUEL SMITH, M.P., said the ground traversed by this paper was so enormous that it was difficult to know where to commence criticism; but, as one who had paid a great deal of attention to this question for a quarter of a century, he must say that the paper struck him as being exceedingly one-sided. It was, in fact, an official apology for the opium trade, and for all the action that this country and India had taken in regard to opium. There were many points on which he could entirely join issue with the writer, but he would only briefly allude to one or two. He was glad to see on the platform Sir Thomas Wade, a gentleman who had had a large official connection with the opium trade in China, and with whom he had had a friendly passage of arms

last year, but for whom he had a great respect. He would first direct attention to the history of our dealings with China in connection with this subject, which, after all, was the crucial point in the controversy. Mr. Batten would lead one to assume that, practically speaking, we had never intervened in the opium trade, save to carry on and continue an old and well established trade. He spoke about it having existed many hundreds of years ago, and being widely spread through China, and carried on by the Portuguese, and afterwards perpetuated by the East India Company, but he said when the East India Company took up the trade in 1773, the total export into China was only 1,000 chests, whereas now it was nearly 100,000 chests. If he was not mistaken, in the year 1767 the export of opium from India to China was only 200 chests. That was the amount of trade we inherited from the Dutch and Portuguese—simply a trade in medicine; and he did not believe that his figures could be disputed. The East India Company, however, took over the trade, and henceforth began to develop it to the utmost of their power.

Mr. BATTEN said he had not given the 1,000 chests as an absolutely correct figure; it was the only one he could find.

Mr. SMITH said his impression was that the quantity in 1767 was very small, and it was purely for the purpose of medicine. He did not believe the habit of opium-smoking had extended in China to any extent worth speaking of at that time. The Chinese Government prohibited entirely the import of opium, and treated it as a noxious and pernicious drug; but the East India Company sold it in an increasing amount year by year to smugglers, who smuggled it in contrary to the law. At the end of the last century, we had got the smuggling trade up to 4,000 chests, the trade in it growing and expanding; and the Chinese Government became more and more determined to stop it, as they observed the ravages it was making, and at last went so far as to make it a capital offence either to sell or smoke opium. They took such strong measures, that they produced the first Chinese opium war in 1839. A gentleman said "No;" but he would simply state the facts. 20,000 chests of smuggled opium were seized by the Chinese, and destroyed; whereupon the English Government made a war upon the Chinese, and compelled them to pay an indemnity for it, and a large addition to the indemnity for the costs of the war. This was one of the most disgraceful wars ever waged. Sir Thomas Wade would hardly say that was not an opium war. He was in China about that time, and afterwards became Ambassador, and he was sure he would not have justified the first opium war, though he believed he took objection to calling the second war an opium war. We forced the Chinese to pay a heavy indemnity, but could not get them to legalise opium.

Sir THOMAS WADE said we did not try.

Mr. SMITH said the Chinese Government refused to do that until after the second war, when we took the capital, and inflicted a crushing defeat upon them; and then, at last, it was legalised. He would quote from a despatch from Sir Thomas Wade himself, written to the British Government, which agreed with everything he could collect on the subject. It was written in 1868. (Mr. Smith then quoted an extract from the despatch, to the effect that every foot obtained by England in China had been obtained by force alone; that we were indebted for the safety we enjoyed at certain accessible points to force; and that all concessions made had been extorted against the conscience of the nation.) That did not look as if our arrangements with China had been amicably made. Sir Thomas Wade was succeeded by Sir Rutherford Alcock.

Sir THOMAS WADE said no; Sir Rutherford Alcock was his predecessor, and the report quoted from was one made by him as Secretary of Legation.

Mr. SMITH then said he would quote from another despatch which he believed was written by Sir Thomas Wade, and in which he gave an account of an interview with a Chinese Minister in which he complained of the hostile feelings of the Chinese towards Englishmen. The Chinese Minister's name was Wang-si-an, and in that interview he asked how things could be otherwise when the Chinese had seen foreigners making war on the country, and the irreparable injury which they had inflicted on the whole empire by the importation of opium. If England would consent to interdict this, and cease either to grow it in India, or to allow it to be imported to China, there might be some hopes of more friendly feelings. They were told by Mr. Batten that opium was perfectly harmless, but its utterly demoralising effects were stated in this despatch to be seen in all those who gave way to the vice. He also said that the extension of this pernicious habit was mainly due to the alacrity with which foreigners supplied the poison for their own profit, perfectly regardless of the irreparable injury inflicted, and the Chinese, therefore, naturally felt hostile to all concerned in the trade. He would now give Sir Rutherford Alcock's own opinion, given to a Committee of the House of Commons in 1871. In answer to the question, "Can the physical, moral, commercial, and political evils of this vice be exaggerated?" his answer was, he had no doubt where there was a great amount of evil there was always a certain amount of danger of exaggeration; but, looking to the universality of the belief among the Chinese, that whenever a man took to smoking opium it probably led to the impoverishment and ruin of his family—the popular feeling which was universal both amongst those who were addicted to it, who always considered themselves moral criminals, and

amongst those who abstained from it—it was difficult to conclude but that what was heard of it was substantially true, and that it was a source of impoverishment and ruin to families. He also said that it was so far a greater mischief than drink that it did not, by external evidence of effects, expose its victims to the loss of repute, which was the penalty of habitual drunkenness. He understood his time was up, or he should have been glad to show that he did not look on only one side of the question. He fully admitted that we had now brought ourselves into a position of such difficulty, through having encouraged and tolerated this trade for 100 years, that probably it was beyond the power of man to suddenly stop it; and any action to be taken now must be made gradually. He did not commit himself to the propositions of the Anti-Opium Society, though he had the greatest respect for it; but, looking at it from the point of view of a politician and a practical man, he thought that violent and sudden remedies were hardly practicable. He believed that, if the British nation thoroughly came to understand the evil which had been wrought in time past, it would insist on demanding a policy which should point towards the gradual extinction of the trade; and he hoped that view would be taken up by members of the Society.

Sir THOMAS WADE, G.C.M.G., K.C.B., said he felt much the same difficulty as the last speaker had admitted. The subject was so enormous that it was exceedingly difficult to deal with it, but he had had the advantage of reading the paper beforehand, and almost flattered himself he should not be called upon, because it so satisfactorily stated most of the grounds upon which he was opposed to the extreme measures suggested by the Anti-Opium Society. In a book—which he had been reading with intense pleasure—viz., the Chairman's work on the Rohilla war, he, the Chairman, remarked with regret upon the tendency to be noticed amongst Englishmen of disparaging their own countrymen. Now we are face to face in this opium question with an undoubted evil. He had a thorough respect for the sincerity with which the majority of the gentlemen composing the Anti-Opium Society attacked the question, but he deplored the unfairness of their arguments and the misrepresentation and misapplication of historical statements which they made. He did not expect that Mr. Smith would have furnished him with so many weapons as he had. In the first place, he quoted at considerable length a statement of his own, extracted from certain words of his which were supposed to have contained an admission that England had forced the opium traffic on the Chinese. Those expressions referred to the unwillingness with which they had made every concession. It was in a very lengthy memorandum prepared, at the desire of Lord Clarendon when Sir Rutherford Alcock was negotiating a revision of the Treaty in 1868. Amongst the numerous proposals submitted to Sir Rutherford Alcock from all the Chambers of Commerce at the ports, there was, amongst a large number of addresses and propositions, upon almost every conceivable subject, a proposition—not at all an unnatural one—that, instead of being confined to the ports we should be allowed to carry our goods inland and establish ourselves at commercial centres in the interior. He (Sir T. Wade) opposed that, because it was not safe to put British merchants and their goods in places where they could not be protected. Why? Because experience showed that they could not as yet trust the feeling of the Chinese, seeing that whatever we had got from them was the result of war. That he admitted. Those first lamentable hostilities from 1839 to 1842 might indeed be called an opium war, because the great act with which they were connected was the destruction of an enormous quantity of opium, for which and for a great deal of other property an indemnity was ultimately claimed; but the same thing would have been done with any Power that England was not afraid to fight, and it was no use to overlook the whole of the antecedent history of our connection with China. That dated from 1720, when the Great Emperor, the second of the line that was then ruling, established the Guild known as the Hong merchants, to superintend trade. Reading the record of what was imposed on English merchants for more than a century, the cruelty and barbarity to individuals, and the humiliating insults inflicted, it was not to be wondered at that we did at last come into serious collision with them. It was a fact that, without a resort to arms, an understanding with the Chinese was then impossible. Thus it was that we came to loggerheads with them at all in 1839. Now, as to the evil that opium had inflicted on individuals, he had seen as much as others had; but he had lived to learn that the evil was not, as he supposed, when he wrote the words just quoted, ineradicable, neither was he justified in impeaching it as an evil without mitigation. Although it was within his ken that there was an enormous amount of mischief inflicted, as there was, by gin and alcoholic excesses, he had lived to perceive that a large number of people took it as Englishman took a glass or a cigar. It had become with the class above that which smoked opium when he first went to China, what the better class of wines had become with us. But, to return, at the time we were charged with having forced the opium trade on China; negotiation with China on the subject was absolutely impossible. If it had been possible, there would have been no war. If it had been, there would have been long ago a mitigation of our trade in opium, which would have removed that reproach from us. As to the extent of our responsibility, could it be supposed that the little quantity of opium—he was indebted to Mr. Smith for his 200 chests—imported into China in the last century could affect a whole nation whose territory was something like 1,200 miles square? What happened with that 200 chests? Was the objection on the part of the Government to opium-smoking in

China such that even that Indian supply was prohibited, except for medicinal purposes? What were the Chinese smoking all that time? When he first went to China, fifty years ago, it was to witness the last act of that wretched war, because it was wretched to fight those who could not stand against you; but, as he had said, war was forced upon us. There was no room for negociation. Had there been, with a man as conciliatory as Captain Elliot, there would not have been that appeal to India to send a force to protect our people. What did the Chinese authorities do? They cut off supplies, seized the property of Englishmen, and destroyed it. A gentleman says it was contraband. Be it so, but it was not because it was contraband that it was destroyed. The Chinese were carrying out that hostility and contempt with which they regarded the foreigners, and there was no possibility of dealing with the Chinese except by a strong arm, and that was the real cause of the first war. He knew it was no use repeating this, because he said it on the memorable occasion to which Mr. Smith had referred, and then he came to him afterwards, and talked about the second opium war as if he had never spoken of any history at all. The history of the importation of the drug had been completely disposed of by Mr. Batten. They were accused of forcing it upon the country, but of all the foreign ministers England had ever had, there had not been a more belligerent minister than Lord Palmerston. He was at the Foreign-office when Lord Napier was sent out to inaugurate a new state of things on the expiration of the East Indian Company's existence, and in his instructions there was not a word of reference to opium. Then came the collision in the manner he explained, and what were the instructions to Captain Elliot and to Sir Henry Pottinger? Not a word about opium. Sir Henry Pottinger did once, in the course of the negotiations, refer to that question, and Kiying told him he could not enter into it, and as soon as Sir Henry Pottinger returned to Hong Kong, after signing the Treaty, his first idea was to remove all opium from the colony; and if there was to be opium trade at all, let it be at Macao. But it was represented to him that if there was an opium trade at Macao, all trade would be at Macao, and none at Hong Kong, and that we should not benefit the Chinese one iota. In 1846 he (Sir T. Wade) was in civil employ in Hong Kong, and went thoroughly into the question of native production. He ascertained that, at that time, the poppy was grown in ten of the eighteen provinces of China, and that in the north-west province, 3,000 miles from Canton, which up to that time had been the only port accessible to England, opium was made which was said to rival the Indian. A conversation between the minister, Wensiang and Sir Rutherford Alcock had been quoted, in which the former had enlarged on the question of opium, but what did he couple with it? Missionaries. He said, "Save us from opium and missionaries, and then things will go well." He did not mention this to fling a stone at the missionaries. What the Minister Wensiang intended to imply was not condemnation of the strange doctrine taught, or of the zeal of the teachers; but the strife about claims, building sites, &c. Of opium, he had a personal abhorrence, so decided, that when laudanum was prescribed him he refused to take it. A colleague whom he had asssisted to bring forward, was to his intense disgust a confirmed smoker. In the year 1858, when we were at war in connection with the Lorcha Arrow affair, Lord Elgin came out with the conviction that we were all wrong, and that the Chinese were in the right; but he came to hold very different views in the course of the two years he spent in China. Nothing, however, was farther from his intention than to impose upon the Chinese any obligations that would be unfair to them; and in his negotiations at Tien-tsin, which, so far as oral communications are concerned, were carried on entirely through Mr. Horatio Lay, the Commissioner of Customs to the Chinese Government, that gentleman, who was present, could testify that from first to last there was never a word said about opium. There were treaties, signed by ourselves and other Powers, with an understanding that we should negotiate a tariff at Shanghai. That was done, but opium was a complete afterthought, even with reference to the tariff. Who suggested to Lord Elgin that he should touch it? The American Minister, who advocated the legalisation of the trade, on account of the irregularities inevitable so long as smuggling continued.

The Rev. F. Storrs-Turner said Lord Elgin was instructed by the Earl of Clarendon, when he went out to China, in the first instance, to get the opium trade legalised.

Sir Thomas Wade accepted the correction, but he maintained that what, to his certain knowledge, stirred Lord Elgin to take the action he did came from the American Minister. But what reference had either of the two latest collisions to opium. The quarrel in both cases was perfectly independent of it. England was forced to fire the first shot—the Chinese are careful always to avoid taking the initiative — but when people talked about injustice to China, no allowance was made for the provocation which England had received. Now as to the reform of the opium smoker, Sir Thomas Wade held in his hand a set of memoranda of interviews he had with the Chinese when he was endeavouring to get the opium taxation settled. He would read one of an interview on the 16th January, 1881. As regarded opium, certain points had been suggesting themselves to Sir T. Wade, upon which the opinion of the Yamen would be valuable. In the first place, as the Ministers were of course aware, the trade in opium, native and foreign, was regarded in different lights by the high authorities of different provinces, and their mode of action was dissimilar. Some were for stamping out native opium altogether,

and restricting the sale of foreign opium by placing prohibitions on the consumption of it. In other provinces it was regarded as a source of revenue, and the habit of opium-smoking was not checked, but the drug was heavily taxed, the vice being turned to account as a means of enriching the exchequer. As these modes of procedure were diametrically opposite, Sir Thomas Wade would be glad to be informed what was the policy favoured by the Central Government? The Minister addressed replied that the question was not an easy one to answer. He did not think that the Central Government had gone so far as to formulate a policy at all. Speaking from a general point of view, however, he might say that if the habit of opium-smoking could be universally and at once abolished, the Chinese Government would be ready and willing to sacrifice the revenue that was at present derived from opium. All sensible men were nevertheless agreed that this was an impossibility. The habit of opium-smoking was beyond the reach of prohibition, and the idea was how to turn it to account. The only way in which it could be turned to account was by making it a source of revenue, and the revenue thus derived was indispensable. There were, moreover, so many other matters that needed reform before the opium question was taken in hand, that it might safely be said that the abolition of opium had not entered the minds of those entrusted with the government of the Empire. Sir T. Wade went on to say that many persons, notably the foreign missionaries in China, had been urging on the British Government through various channels the advisability and the equity of abandoning their connection with opium. Suppose, for as yet it was a pure supposition, that the British Government were eventually to effect a gradual diminution of the opium trade from India, by limiting the import to an increasing degree, year by year, until the trade was abolished altogether, did the Minister think that such an arrangement would meet with the approval of the Chinese Government? The Minister addressed, who again protested that the question was a difficult one to answer, replied that in his opinion such a plan would be useless. As long as the habit existed, opium would be procured somehow, and if it did not come from India it would be procured elsewhere. Any serious attempt to check the evil must originate with individuals. As long as men wanted to smoke and insisted on smoking, they would smoke, and a spontaneous abandonment of the habit on the part of the people would regulate the supply. Nothing short of this would do any good, and philanthropic efforts to check the evil in the manner suggested by Sir T. Wade would affect the revenue only, without in any way reaching the root of the mischief. That was all that he, Sir Thomas Wade, contended. There was a remedy. Nothing, he believed, would eradicate what was mischievous but the reform of the individual, and nothing but the evangelisation of China would produce the reformation of the individual necessary to accomplish that reform. He said that to the Anti-Opium Society, and to everyone else interested in the task of evangelisation; but for the purpose of evangelising China they must go to work in another way. We had not been sending to China the class of men that would influence the literary class who represents the mind of the country, and until we sent people competent by education to place themselves on a level with the literary men of the country, and to speak to them in a way that would induce them to believe that we also were scholars, it would be impossible to introduce Western views, either theological, educated, moral, or, which with the Chinese was the same, political, any more than could we attempt to protestantise Ireland without first having converted the priests.

Mr. HORATIO N. LAY, C.B., said that he must premise that opium was introduced into China, under the name *afuyung*, from Persia, Syria, and Turkey, as far back as the 8th century. We were, therefore, not responsible for imparting to the Chinese their taste for opium. Its import continued for centuries, and, in the year 1722, it was formally legalised by the Chinese Government, entered in the tariff as a dutiable article, paying £1 sterling per picul of 133⅓ lbs. The duty was directed to be received at Canton, through the Hong merchants, in exchange for tea and silk. As our first Embassy (Earl Macartney's) did not proceed to Pekin till 1792, it cannot be affirmed that the legalisation of the article was not the spontaneous act of the Chinese Government. Legislation continued for 70 years, during which period the cultivation of the poppy was largely extended in China. In 1799, the Edict of 1722 was cancelled, and importation was forbidden, but nominally only, the import being, as before, openly permitted at Canton—then the only port open to trade—and carefully fostered by the Chinese, the highest officials of the province, and at Pekin, partaking in the gains from the traffic. It was in the reign of the Emperor Keaking, who had cancelled legalisation, that our second Embassy (Lord Amherst's), visited the capital in 1816. In the annals of neither this nor the previous embassy do we find the slightest allusion to opium—no complaint that we had brought it into the country, contrary to the wishes of the Government. Thus we have the facts, which are unimpeachable, that for centuries China admitted opium; and that she, of her own free will, encouraged and stimulated its import by the enactment of 1722, which was suffered to continue in force down to 1839, a period of 117 years. On the dissolution of the East India Company, Lord Napier was sent out, in 1834, to be H.M. Superintendent of Trade. He proceeded to Canton to present his credentials, but the Chinese declined to receive him or his credentials. If he had anything to say, he must communicate through the Hong merchants (a guild which had the monopoly of trade with foreigners), or trade would be cut off. He was treated with the utmost indignity, even his baggage chests were broken open, while the keys were within reach;

and when he took his departure in a passage boat for Macao, he was escorted by Chinese soldiers, who kept him for five days upon the river in a broiling sun, upon a passage that could have been accomplished in as many hours. The insulting treatment, joined to the sufferings he endured, induced a fever, from which he died a few days after the boat reached Macao. Sir George Robinson succeeded Lord Napier, and complained of "disgraceful and humiliating annoyances." In 1835, the Viceroy proclaimed eight regulations of trade for the guidance of the foreign community, in in which it is notable that opium was not even mentioned, and Sir George Robinson, at that date, reports the quiet and regular progress of the opium trade. In 1836, Captain Elliott became H.M. representative. He was instructed by Lord Palmerston not to re-open communications through the Hong merchants, but only with the Viceroy or other responsible official. From 1821 there had been a rapid increase in the import of opium. The duty and excessive charges upon woollen and other goods had led to the importation of dollars. The Americans at that time imported dollars and Turkey opium to pay for tea and silk. The difficulty experienced in procuring dollars operated powerfully, wrote one of our merchants in an able letter in the Blue Book, in stimulating the imports of opium, which, together with other imports, being insufficient to pay for the tea, silk, &c., the balance had to be taken in China gold and silver to the extent of 2,000,000 dollars per annum. The fears that China would be drained of her precious metals—the probable cause of the revocation, in 1799, of the legalising edict of 1722—were re-awakened at the court. Conflicting advice was tendered by the highest officials in the empire. Some were in favour of absolute prohibition of opium. Some were in favour of "a return to the former plan," by re-legalising it, and prohibiting the export of gold or silver. The latter counsel was given by the high authorities at Canton, and at first prevailed. Legislation was decided on, and the functionaries there were instructed to make preparatory arrangements accordingly. The Court, however, wavered between re-legislation and prohibition for two years, when the fears that no edicts against the export of silver could be made effectual prevailed, and prohibitory measures against opium were the final decision. Such is the purport of all the Chinese State papers, of Lin's letter to the merchants, and not a word from first to last is there about our having forced, or having conceived a purpose to force, China to receive opium. When Captain Elliott apprised Lord Palmerston that there were indications of a purpose on the part of the Chinese Government to stop the importation of opium, Lord Palmerston wrote as follows:—"June 15th, 1838.—Her Majesty's Government cannot interfere for the purpose of enabling British subjects to violate the laws of the country in which they reside; any loss, therefore, which such persons may suffer in consequence of the more effectual execution of the Chinese laws on this subject, must be borne by the parties who have brought that upon themselves by their own acts." Is there any trace here of forcing opium on the Chinese? There can be but one answer. Lord Palmerston had repeated in 1837 his instructions to Captain Elliott as to communicating only with the Viceroy or other responsible authority, but the Viceroy declined to receive any letters from Elliott unless the word "petition" were used. Captain Elliott, therefore, broke off communication with the Viceroy towards the end of that year. Matters continued in this state until early in March, 1839, when Commissioner Lin suddenly appeared on the scene, armed with special powers to put down the opium traffic. Ignoring Captain Elliott, he addresses the foreign merchants direct, commanding them to deliver up to him all opium in their possession. At the same time, he surrounds the English factories with soldiers, takes away all the native servants, and cuts off all provisions, and holds Captain Elliott and the 200 merchants as his prisoners within the factories. Captain Elliott proposes to give Lin an order for the delivery to him of all the opium on board the receiving ships. Lin answers that if in three days his "commands" are not complied with, the fresh water shall be cut off, in three days more all provisions shall be utterly cut off, and a further delay of three days will involve the death penalty to all. Captain Elliott complies, and sends Lin an order to receive 20,283 chests within the time named. Lin receives the opium, but does not release H.M.'s representative according to promise, but retains him a prisoner, along with the merchants, for a period of seven weeks. Is any word uttered by H.M.'s Minister about compensation for the opium thus delivered up? None; and nothing about our having forced it on the Chinese by Lin. Reporting the circumstances to Lord Palmerston, Captain Elliott wrote:—"The utmost conceivable encouragement, direct and indirect, on the one hand, and sudden violent spoliation on the other, are the characteristics of the Chinese measures concerning opium. It has been a confusion of terms to call the opium trade a smuggling trade; it was a formally prohibited trade, but there was no part of the trade in this country which had the same active support of the local authorities. It commenced, and has subsisted by means of the hearty connivance of the mandarins; and it could have done neither the one nor the other without their constant countenance." In his remonstrance to Lin on his bad faith as to his release from imprisonment, Elliott tells Lin the unpalatable truth, that "the traffic in opium has been chiefly encouraged and protected by the highest officers in the Empire, and that no portion of the trade had paid its fees with so much regularity as this of opium." Lin answered the protest, not by a denial of its truth, nor by complaint that we had brought opium in defiance of Chinese law, but by moving down towards Macao, where Captain Elliott had taken up his quarters, with 2,000 troops, and by issuing orders that Captain Elliott's servants should

be again withdrawn, and that all supplies to British merchants at Macao should be stopped, with the result that Elliott was obliged to quit Macao, and take refuge on board H.M.S. *Volage* at Hong Kong, disregarding a further demand from Lin that a British subject should be handed over to him for punishment, and that the British merchant vessels who, in consequence of his violent methods, had repaired to Macao, should be required to re-enter the Canton river. Lin had ruined the trade and wanted to restore it, while he had lost all control of the opium traffic. Lin expelled British merchants from Macao, then cut off all supplies to Hong Kong, and directed the water to be poisoned. He commanded the people to fire upon and seize any British subject found on shore purchasing provisions, and some of our people were cut off. And what was Captain Elliott's rejoinder to all this? He offered the other cheek for Lin to smite. Closing his eyes to what had transpired, he proposed to renew official relations with the authorites from Macao. On the 24th of September we find him actually submitting to Lin an offer to concert measures for the prevention of the import of opium in British vessels, and making detailed propositions. And how is this meek attitude treated by Lin? With scornful disregard—a fine object lesson for all time. On the 9th of October H.M. Representative perseveres in appeals to Lin:—"His wishes had been carried out in all respects, the time may have come for British subjects to be permitted to return to Macao." No word throughout, be it noted, on the part of Captain Elliott or of Lord Palmerston, as to compensation for the opium taken by *force majeure*, without any previous notice from the Chinese Government of its change of policy; nor on the part of Lin as to our having imported opium contrary to the wishes of the Government. Lin was bent on war, and, by way of reply to the last communication, ordered attacks upon English vessels; and several British subjects were wounded or killed. In one case, a passenger was left for dead, barbarously wounded, with his ears cut off and stuffed into his mouth. Finally, Lin crowned all his proceedings by issuing a proclamation, which amounted to a declaration of war, declaring trade at an end with Great Britain, and forbidding, after December 9, 1839, the importation of British goods under any other flag. This declaration being issued, too, nine months after the surrender of the opium, after the special offers of the British Minister to cement measures for the suppression of the opium trade in British ships, and after the repeated overtures for the renewal of relations made by Captain Elliot. It was not opium then that produced the war, for Lord Palmerston had already, in 1838, declared his views, and no claim was ever put forward by him for the opium taken possession of by Lin. But war was forced upon us. That left Lord Palmerston no option but to despatch on expedition to China to demand redress. It took two years to bring the Chinese to terms, and though Lord Palmerston made them pay for the opium seized in 1839, so far from taking advantage of the occasion to demand the re-legalisation of opium on the conclusion of the Treaty of Nan-kin, every means was proferred the Chinese Commissioners to control its import, if they so desired. They never so desired, as could be abundanty proved.

Sir Lepel Griffin, K.C.S.I., said he thought the question, whether the war in China arose on account of the opium or not, had not much interest for the people of England at the present moment. In order to counteract the exceedingly mischievous tendencies of the doctrines of the Anti-Opium Society, it was necessary to prove to the people of England, in an easy and simple manner, that the attacks made on opium were both false and foolish: that opium smoked or drunk in a reasonable manner, and not to excess, was not more dangerous than tea or tobacco. When at the head of the Administration of Central India, he was also the Collector of Opium Revenue from the native States, amounting to upwards of £2,000,000 sterling a year; and it had been his duty to study the question, and understand the effect of the cultivation and use of the drug, both from a social and fiscal point of view. He thought its ordinary and moderate use to be healthy, and, as a judge, he had never known a crime occasioned by its use. Could the same thing be said in England with regard to the the use of alcohol? The majority of the Rajputs in Central India ate opium—at least, it was the custom of the country. In the other part of India in which the greater part of his service had been spent, the Punjaub, the Sikhs were large consumers of opium, and they were physically, morally, and mentally, the two finest races in India. Gentlemen might smile and hold up official Blue-books, but the Sikhs and Rajputs, who were the opium consumers of India—excluding the population of the Delta, who took it for medical reasons—were the finest races in the continent. He found that persons who defended temperance were the most intemperate; they would neither listen to argument nor allow other people to say a word in defence of opinions opposed to their own. Opium-smoking was not a common habit in India, where it was ordinarily drunk, but smoking was less injurious than drinking it. With reference to the exclusion of opium land from grain cultivation, of which they had heard so much, Malwa, the province of Central India, in which all the best opium land lay, was the only part of India he knew in which, throughout historical times, there had been no famine. He could not but observe that it was an astonishingly sad thing to see, in the latter part of the 19th century, a society possessed of such mischievous, homicidal characteristics as the Anti-Opium Society. If their convictions were to prevail, they would rank as destroyers of the human race with cholera and famine, because a very large part

of the population of India—especially that inhabiting the fever-stricken malarious districts of Bengal—was only preserved from death by the habitual use of opium. That was known to every person of any authority in the room.

Mr. J. G. ALEXANDER, LL.B. (Secretary of the Society for the Suppression of the Opium Trade), said Mr. Batten began by speaking about trade, and there seemed to be an assumption underlying that part of his paper that every trade that brought money to a country must necessarily be beneficial. That was not so; a trade which flourished on the impoverishment of another country could not but be detrimental. He believed this trade was really detrimental to India and Great Britain, because it was the means of impoverishing the Chinese people. It did them no good, but dried up the sources of trade with China, and therefore must necessarily be an economic blunder. For the purposes of this argument, he was assuming that opium was, as there was overwhelming evidence to show that it was, a great curse in China. It was also assumed in that part of the paper that the land devoted to the cultivation of the poppy could not be used for any other purpose; but only two or three years ago, a Commission was appointed by the Government of India to inquire why it was that the ryots in the poppy-producing districts were not willing to extend the cultivation of the poppy, and that the area was diminishing. It was reported that there were three articles competing with the poppy—potatoes, cotton, and sugar. The poppy was grown on the very finest and richest land, which might be applied for the production of other articles which, instead of impoverishing the world, would enrich it. Something was said about the superior quality of the opium supplied from India in preference to that of China, but that superior quality consisted in having more intoxicating and deleterious power. In the reports which Sir Robert Hart collected, some ten years ago, several Consuls showed that it required a greater quantity of native opium to intoxicate, and therefore it did not do so much harm as the Indian. He therefore failed to see any force in the suggestion that the Indian opium was superior. Then there was the question raised. Could smuggling be prevented? With regard to that he would appeal to the reports from Burma. Several of the officials from Burma, who had given evidence on the subject, said that it could be dealt with, and Sir Charles Aitchison himself said, in his Memorandum of 1881:—"Already the price of opium is artificially forced up to the maximum, presenting the very strongest temptation to the smuggler. The pecuniary temptation cannot become much greater than it is if opium were altogether forbidden, and we should have the sympathies of the people with us in the suppression of smuggling." Mr. Batten quoted a report dealing with Assam, in a recent Blue-book, but he had a striking piece of evidence to the contrary effect. Mr. C. A. Bruce, the superintendent to the British Government of the tea plantations in Assam, said the British Government would confer a lasting blessing on the Assamese and new settlers if immediate and active measures were taken to put down the cultivation of opium and stop its importation; that if something of this kind were not done, and measures soon taken in consequence of this report, thousands about to immigrate would be affected by the opium mania—that dreadful plague which had depopulated this beautiful country and turned it into a land of wild beasts, and degenerated the Assamese—a very fine race of people—into the most abject, servile, crafty, and demoralised race in India.

Dr. MOUAT said that was utterly untrue; he spoke from personal knowledge.

Mr. ALEXANDER said Mr. Bruce went on to say would it not be the highest blessing if a humane Government stopped these evils with a single dash of the pen and saved Assam? He made these quotations from Lord Justice Fry's book; facts and evidence that was exactly similar to the evidence from Burmah. Mr. Batten had summed up that evidence on the one side in a contemptuous sentence or two, but if they would look at the Blue-book, they would find the evidence from Burmah against opium was overwhelming. The Government of India acknowledged it to be "the unanimous opinion of respectable Burmans, and official and non-official Europeans, that the use of opium by Burmese was deleterious and harmful in a special degree."

Mr. BATTEN said that was only an opinion; there was no fact quoted, and not a single instance of a Burman being hurt by opium.

Mr. ALEXANDER said was it to be supposed that the whole Burmese people, the whole of the officials and the whole of the respectable Europeans resident in Burmah, formed such an opinion without any facts? And the same with the whole body of missionaries in China. With one single exception, which had been quoted, there was a practically unanimous opinion of the missionaries, including many medical missionaries—many of the ablest men who had gone forth into the mission-field—that opium was an unmitigated curse to the Chinese. As Archdeacon Moule said—What interest had the missionaries in decrying their country? They were as much patriots as other men; but they were met with this question at every step. He saw before him a medical missionary who could testify to that. Wherever they went, in most parts of China, they were met with the cry, "You brought opium here, and do you come and preach religion?" Sir Charles Aitchison's memorandum was based on facts; naturally officials would speak of their knowledge, not what they had seen. A circular was issued instructing Commissioners to obtain the opinion of district officers and educated and intelligent natives on the question of the increase of opium-smoking amongst the Burmese, and submit

any remedial measures of a practical kind; and a little further on he said the papers submitted presented a painful picture of the demoralisation and misery produced by this habit. The responsible officers in all parts of the country bore testimony to it. That was ten years ago, and to-day the Indian Government said it was the unanimous opinion of respectable Burmans, and officials, and non-official European residents. Would it be any better if they mentioned a case here and there? The reply would then be made, "You have picked out isolated cases." These were the conclusions drawn from a very large number of facts and observations. As regards the question whether there was an ancient use of opium in China, he would only say that his friend, Professor Legge, said there was no evidence of it that he was aware of in the early works of China. Mr. Batten had referred to one extract, which he did not read, to prove that the intoxicating properties of opium were well known in China 300 or 400 years ago, but he thought it showed nothing of the kind. That was the only extract brought forward until about 200 years ago, when, undoubtedly, the fashion was introduced, probably from Java. That England was the first to introduce opium into China, and that smoking was absolutely unknown before the English had to do with the trade, was not a contention that his society had ever been responsible for. They admitted that it existed on a small scale; the taste was already created to a limited extent, but that was all. With regard to the Roman Catholic missionaries, up to the end of the last century there was no trace of it to be found in their works.

Mr. BATTEN—Nor now.

Mr. ALEXANDER said he had certainly seen statements from Roman Catholic priests to this effect; he had seen one from the "Weekly Register" only a year or two ago, which was put into the "Friend of China," and the late Cardinal Manning used to say that the Roman Catholic missionaries gave exactly the same evidence as the Protestant missionaries as to the prevalence of the habit throughout China. Why did the Government of China entertain this pious opinion, as Mr. Batten called it? What was the foundation of it? It was a remarkable fact that among all the testimonies collected there was not one bit of evidence quoted from a Chinaman in support of the drug. The Rev. F. W. Baller, who had travelled in 13 out of the 18 provinces of China, and amongst all classes, said he had never found a Chinaman—least of all those who smoked opium themselves—prepared to defend the habit. Whence did that delusion on their part arise, if it were really so beneficial as their Indian friends said? Throughout China the Christian missionaries did not admit opium smokers into their churches. He would conclude by saying that the undoubted blunder in the memorial, which had been made so much of, rose from the accident (for which he was personally responsible of two sentences, one relating to Lahore and the other to Lucknow, being transposed. There were some gentlemen who knew India exceedingly well, in the society, and amongst those who signed the memorial was the venerable Sir Arthur Cotton.

[Mr. Alexander has sent the following addition to his remarks at the meeting:—In Mr. Batten's paper he quoted the evidence of Mr. Brereton, and told us that "he was in no way engaged in the opium trade, and had no pecuniary interest in it." At page seven of "The Truth about Opium," Mr. Brereton says: "I have been the professional adviser of the opium farmer" (*sc.* at Hong Kong) "for at least ten years, and from him and his assistants I have had excellent opportunities of learning the truth about opium." Would it be correct to say of the solicitor to a great distillery company that he had "no pecuniary interest" in the trade? and would his testimony as to the absolutely innocuous effects o whiskey drinking be accepted as w olly disinterested (2) Mr. Batten argues that the effect of abolishing the opium trade would be to cause a still greater fall in exchange, because China is paid by Indian opium for the excess of her exports to England. I submit that the contrary would be the effect. At present the opium trade causes a drain of silver from China to India (see my "Substitutes for the Opium Revenues," p. 25). If the import of opium into China ceased, China would have to take payment for that portion of her exports which is now paid for by opium from India, either in goods or in money; doubtless she would take it partly in cach. Thus, instead of exporting silver, as at present, she would absorb silver; for "India and China are now the only countries that freely coin or absorb silver" (Memorandum on the administration of India during the past thirty years: presented to Parliament, 1889, c. 5713). The tendency would, inevitably, be to counteract powerfully the steady fall in the price of silver, that has so long embarrassed the Indian Government and the commerce of the East. The greater demand for British and Indian produce would also stimulate Eastern trade. (3) The quotation from my pamphlet, "India's Opium Revenue," no longer represents the extent of the society's aims. Since that pamphlet was written the society has advanced its programme, which now includes the immediate stoppage of the export of opium from the native States of Central India, on terms to be equitably arranged with these States Their share in the profits of poppy cultivation has been reduced by Chinese competition, and the consequent fall in prices, to so very small an amount that this would form no appreciable addition to the cost. It would doubtless be far less costly, quite as easy, and much more satisfactory, to arrange with the native chiefs for the suppression of the poppy culture in their territories, than to establish a Customs barrier around them. (4) Mr. Lay quoted the statement made in 1836 by the Chinese

Governor of the two Kwang Provinces, that from 1723 to 1795 there was no regulation against purchasing or inhaling opium. This statement, however, is contradicted (as was pointed out by Mr. Gillett at the meeting) by the admissions made on the trial of Warren Hastings. It is also at variance with the letter from Mr. Fizmagh, printed in the House of Commons Committee's report of 1783, which states that "the importation of opium to China is forbidden on very severe penalties. The opium on seizure is burnt, the vessel in which it is brought to the port is confiscated, and the Chinese in whose possession it is found for sale is punishable with death." Dr. Edkins' Yellow-book on the "History of Opium in China," has cleared up the matter by showing that in 1729 an edict was issued making the opium trade unlawful. Dr. Dudgeon, however, from whom Dr. Edkins obtained the materials for that part of his treatise, informs me that the latter has not stated the facts quite accurately; the decree of 1729 only applied to the island of Formosa, and it was not till a few years later (about 1735), that the first general decree, prohibiting the trade throughout China, was issued. From that time till 1858 it remained unlawful.]

Sir GEORGE BIRDWOOD said that the Chairman would have called upon him to speak, but it was too late then for any further speeches, and that his own remarks, and those of any gentlemen who had sent in their names, would be printed in the *Journal*.

The CHAIRMAN said there was no time for him to offer any oral remarks of his own, and he would simply conclude the meeting by proposing a vote, which he was sure they would all concur in, of thanks to Mr. Batten for his very interesting paper.

The proposition was carried unanimously, and the proceedings terminated.

Sir JOHN STRACHEY, the Chairman, has communicated the following remarks, which he would have made at the meeting, had there been time:—In my own opinion, no more able and complete and accurate account of all the more important facts of the case has ever been given to the world than is given in Mr. Batten's interesting paper. I only wish it were possible to think that the truths Mr. Batten has told could receive as wide a diffusion in this country as that which has been given to the errors and misstatements, as I believe them to be, which are scattered broadcast over the land. I must say something of my own experience on this subject. I passed some thirty-eight years of my life in India, and I should not be very greatly exaggerating if I were to say that, during that time, I held almost every office which a member of the Civil Service in India can hold, beginning from offices of little importance, to the very highest posts in the service of the State. I was brought into personal communication with all classes, from the greatest princes to the humblest ryots. I am entitled to say that I can speak with some knowledge of the facts, as they regard the people of India, and the policy of the Government. Now, I have always felt in regard to this controversy that the object to be aimed at is to learn the truth, and to act upon it. Thousands of excellent people in this country, of whom I desire to speak with all respect, because although I know them to be mistaken, I must fully recognise the perfect honesty and nobility of their aims, believe that we are ruining with a horrible poison millions of Chinese, and that not content with this iniquity, we are encouraging the consumption of opium among our own subjects in India with similar terrible consequences. If this were true, I should say for my part, that whatever might be the results to the Government or to the people pecuniary, or economical, or political, or otherwise, however difficult or dangerous it might be to find substitutes for the loss that the suppression of opium cultivation in India might entail, there could be no doubt about our duty. I am confident that, when Mr. Batten tells us that the total value of the poppy crops of India exceeds £13,000,000 sterling a year, he understates rather than overstates the fact. I know that all that Sir Lepel Griffin has told us about Sikhs and Rajputs—the most martial races of India—and the political dangers that would follow on the attempt to interfere with the consumption of opium, to which they have been accustomed for centuries, is perfectly true. Nevertheless, if I believed that the Government was committing the abominable iniquity with which it is charged, of demoralising and destroying millions of people, I should say that, whatever be the consequences, this iniquity ought not to be allowed to last for a single day during which we can prevent it. But what are the facts? It is impossible for me now to enter into the evidence on which my conclusions have been based. I can only give the conclusions themselves, which the experience of a lifetime has impressed upon me. I believe it to be proved to demonstration, that opium is not this terrible poison. The vast majority of those who consume it, consume it in moderation, and so consumed there is no one of the stimulants that enter largely into the consumption of the world that is more innocent. I will go further, and say, more beneficial. It is as innocent as the wines of France or Italy are to the people of those countries, or as undoctored beer is to the people of England or Germany. Like all other good gifts of nature it may be abused, but even when this happens, whatever it may be to the individual, it is less harmful to society than the alcohol, which is the curse of our own country. This opium question has two aspects; one, as it concerns the people of India, the other as it concerns the Chinese. As regards the people of India generally, I would ask you first to remember what India is. It is a vast continent as large as the whole of civilised Europe, with a greater population, for it contains

some 280,000,000 of people. It consists of a multitude of countries differing from each other far more widely than the countries of Europe differ among themselves. In some of these countries, as we have been told, and as I shall have again to mention, certain classes of the people have from time immemorial, consumed opium. But these classes constitute, numerically, an absolutely insignificant proportion of the population of India Speaking in general terms, the consumption of opium in India is so infinitesimally small, that I may say, without exaggeration, that no opium question exists at all. We are told, however, that the consumption of opium has been rapidly increasing, and that it has been fostered by our Government. These statements are absolutely baseless. The increase of population under British rule has been enormous; but there is every reason to believe that the consumption of opium in India, under native rule, 150 years ago, was actually greater than it is now. However this may be, and without attempting to go back to times of which we know comparatively little, this at least is certain, that, although the population goes on rapidly increasing, the consumption of opium, instead of increasing, has diminished. It is certainly smaller now than it was, for instance, ten years ago. This has been the result of the policy of the Government of India. By a vigorous system of Excise, it raises the price of opium consistent with the prevention of extensive smuggling, and reduces consumption to a minimum. The sole present danger is that this policy may be carried too far; and some authorities believe that this is already happening. The danger is that by making opium too dear and difficult to obtain, we may not only encourage smuggling, a comparatively small evil, but may cause people who have been content with the moderate use of opium to have recourse to cheap and noxious stimulants procurable from weeds which, I may almost say, grow near every man's door. Although, as I have said, the consumption of opium by the people of India generally is infinitesimally small, it has been consumed for centuries by certain classes in Northern India. It is an indisputable fact, as Sir Lepel Griffin has told us, that these classes, especially the Rajputs and Sikhs, are precisely the finest races physically in all India. I have often thought that the best practical answer to those who inveigh against the use of opium would be, if such a thing were practicable, to bring one of our crack opium-drinking Sikh regiments to London, and exhibit them in Hyde-park. There is no more vigorous, manly, handsome race of men to be found, not only in India, but in the world. They are the flower of our Indian army, and one of the bulwarks of our empire, and yet the use of opium among them is almost universal. It has always seemed to me a significant fact that among all the passionate appeals to British ignorance, we never hear one word about the Sikhs. We hear a great deal about so-called opium dens, which, after all, are very few and far between, but we hear nothing about the constant consumption of opium among the finest populations of India. People talk glibly about suppressing by law the growth and consumption of opium in India. I have great faith in the power of folly and ignorance, but I trust that I may not see the day when the attempt is made to deprive Sikhs and Rajputs of—I will not say a luxury —but one of the innocent and beneficial necessaries of their lives. I read the other day, referring to this subject, some remarks by a most accomplished writer, who speaks on Indian subjects with high authority—I hope Sir William Hunter will pardon me for quoting him. He said that a law such as that to which I have just referred, could only be enforced in British territories by bloodshed and arms, while in native States it could not be enforced at all. I might enlarge much more on such considerations. They involve issues of political gravity, the existence of which appears to be unknown and unsuspected in this country. I repeat, however, that these classes which consume opium, highly important as they are politically, are numerically an insignificant fraction of the Indian population, and that, so far as the people of India generally are concerned, no opium question really exists. I must now say something about China; but Mr. Batten and other gentlemen, who have spoken with the highest authority, have said so much on this part of the subject, that I shall add very little, and I can add really nothing that is new. There can be no greater delusion than to suppose that China depends on India for her supply of opium. If no opium were exported from India, the consumption of China would remain practically unchanged. Indian opium in China is a luxury of the comparatively rich. If they were deprived of it, they would suffer as the richer classes would suffer here if they were deprived of the choicest vintages of Bordeaux and Burgundy, or if tobacco smokers got no more cigars from Cuba. In such a case, in this country, the frequenters of beer-shops and gin-palaces would be conscious of no hardship; and the population of China would be equally unconscious if it received no opium from India. A single province of China produces more opium than the whole Indian Empire. Whole provinces are covered with the poppy; the cultivation goes on increasing, without any interference on the part of the Government of China. Even, therefore, if it were true that the people of China are being ruined by opium, the cessation of imports from India would not diminish the evil. But it is certainly not true. The vast majority of the consumers of opium in China consume it in moderation; and it is, as I said before, as harmless as the wine and beer of Europe. Moreover, as Mr. Batten has told us, if the Government of China should wish to undertake the task of stopping the consumption of opium, and preventing the importation of opium from India, it can do so if it pleases. It can prohibit the importation, or can impose any restrictions that it likes.

Meanwhile, there is nothing with which we need reproach ourselves. If, as I wrote myself some years ago, in deference to ignorant prejudices, India is deprived of the revenues which she now obtains from opium, an act of folly and injustice will be perpetrated as gross as any that has ever been inflicted by a foreign Government on a subject nation. India now possesses the rare fortune of obtaining from one of her native products a great revenue, without the imposition of taxes on her own people; and we are asked to sacrifice the manifest and vital interests of those people, to whose good we are pledged by the highest duties, in hope of protecting others, against their will, from imaginary evils; in other words, to inflict certain injury in pursuit of a benevolent chimera, which must elude us. Truly, to use the words of Condorcet, "L'enthousiaste ignorant est la plus terrible des bêtes féroces." I wish to say only one thing more, and it is that with which I began: what we want is the truth. How, I may be asked, if this widely-spread belief regarding India is erroneous, what is the explanation of its prevalence? My answer is, that the ignorance that prevails in this country regarding everything Indian is enormous. The ignorance about opium is on all fours with the ignorance on every other subject connected with India, and this ignorance is not confined to those who we expect to be ignorant, but extends to the most highly educated classes. It extends to all Indian subjects, history, geography, the condition and habits of the people, the constitution of the Government, in fact to everything. I will give an illustration which always seems to me to have an useful bearing on this opium question. There are many curious delusions about India which it seems impossible to kill. When I hear educated Englishmen talking about opium, I am often reminded of some admirable remarks of Sir Henry Maine on Mr. Buckle's "History of Civilisation." Mr. Buckle derives all the distinctive institutions of India, and the peculiarities of its people, from the fact that the exclusive food of the natives of India is rice. It follows from this, he tells us, that caste prevails, that oppression is rife, that rents are high, and that customs and law are stereotyped. I have no doubt that if Mr. Buckle had been asked he would have said that the same cause accounted for the consumption of opium in India. I sometimes ask my English friends when they talk about opium what they suppose to be the ordinary food of the people of India. The almost universal answer given, perhaps with some air of displeasure that they should be asked such a foolish question, is that of course it is rice. I believe that nine-tenths of the educated men and women of this country believe this to be true. When they have not learnt such an elementary fact as this, that throughout the greater part of India rice is no more the ordinary food of the people than it is in England, how can we be surprised if they do not know the truth about opium. I cannot pretend to be hopeful that this ignorance will be dispelled before it has inflicted some ruinous injustice on the unfortunate people of India. In conclusion, I would ask those who have accepted these views about the iniquity of the Indian Government in regard to opium, to ponder the words of a wise and benevolent man—John Stuart Mill. He had better means of knowledge and knew more about India than almost any Englishman that I have heard of who had not lived long in that country, and he declared his conviction that our Government there had been "not only one of the purest Governments in intention, but one of the most beneficent in act ever known among mankind." This was true when it was written, and it is truer now. I believe that there is no Government in the world that strives so honestly and resolutely to think of nothing but the highest interests of the people it governs. I believe that there is no country in the world in which the men who carry on the administration are more able and upright, or who have a more true regard for the welfare of those committed to their care. We, who have spent our lives in India, are not all fools or impostors. It is, as Mr. Batten has most truly observed, remarkable that no single instance can be quoted of an Englishman who has been directly responsible for the well-being of India, and who has had an important voice in its administration, who has held the views against which I have been protesting. That, as Mr. Batten said, has been left for irresponsible persons in this country, whose want of knowledge is patent to every one who has studied the question on the spot. When I hear the Government of India, charged with the abominable wickedness of poisoning its own subjects, and poisoning millions of Chinese for the sake of filthy lucre, there is only one reason which prevents me from being filled with indignation, and this is that I know that these charges are the offspring of ignorance alone. Unfortunately this does not make them less serious, for of all the enemies to human progress ignorance is the most formidable, and is especially formidable when, as in this present case, it is combined with honest enthusiasm and an anxious desire for that which is right.

The following communications from gentlemen who sent up their names, and were prepared to speak, have been received since the meeting:—

Sir GEORGE BIRDWOOD—I have already said all that I have to say on the only phases of the opium question that interest me, namely, the historical and physiological, in my letters to the *Times* of the 6th December, 1881, and 20th January, 1882; which have moreover been reprinted at length in Mr. Brereton's "Truth about Opium," and Mr. Sultzberger's "All about Opium," and are repeatedly referred to in Mr. Haines's "Vindication of England's Policy with regard to the Opium Trade," a most scholarly volume, which ought to be in the hands of every serious student of the history of the state monopoly of the production of opium in India. My experience of the habitual use

of opium, and the results of my researches into its origin and spread throughout the East are, therefore, on easily accessible record; and were the controversy on the subject scientifically conducted they would require no reiteration here. But as a paid agitation against the opium revenue is again being organised for the express purpose of making its abolition a test question for Parliamentary candidates at the next general election, it becomes the duty of everyone familiar with India and the condition of its ancient people, to testify, whenever and wherever challenged to do so, to the truth in regard to their indulgence in opium, and its effects on them. But before I proceed to briefly re-state my personal experience of the habitual use of opium in the East, which is the only part of my contribution to the discussion on Mr. George Batten's powerful paper of any practical pertinence to the immediate controversy, I would venture to indulge myself in treating for awhile of certain points connected with the ancient history of opium, of deep suggestiveness to students of the history of Eastern commerce and art. It has always been accepted that the word opium is the Greek word *opion*, the diminutive of *opos*, "juice;" and there is not an Eastern or Western word for true opium which is not a variant of this Greek word *opion*. It has, however, recently been suggested that the Sanskrit word *ahipana*, or *apana*, is an original and indigenous Indian word for opium, and, inasmuch as Pliny mentions [xx, 76-80] a spurious opium-yielding poppy called *aphron* ["foam;" *cf.* Aphro-dite *ex* Ashteroth], that the Greek word opium may have been from the Sanskrit *ahipana*, which, in ignorance of its true parentage, was fathered on *opos*. But the hard fact is that the word *ahipana*, or *apana*, does not occur in any Sanskrit book until it appears, for the first time, in a Sanskrit dictionary, published about seventy years ago. The Greeks and Romans knew poppies, and opiate preparations from poppies, from the earliest ages of their history, and the *pharmakon nêpenthês*, the praises of which, as a "grief assuaging drug," are so rapturously sung in the Odyssey [iv. 221], was probably the primitive form of the Egyptian opium (*opium Thebaicum*) of a latter date. But it is very doubtful whether the first poppy known to them was the *Popaver somniferum*, from which alone true opium has ever been prepared; and it is most probable that their original opiate poppy, and the original opiate poppies everywhere, were certain species of red poppy, resembling *P. Rhœas*, which, from East to West, dye, in bright blood red, the midsummer fields of Middle Asia and Europe. I believe one of these red poppies of Middle Asia to be the original source of some primitive indigenous opiate preparation in China and India, as distinguished from the true opium introduced into these countries from Egypt, and Asia Minor and Persia, through the intermediation of the Arab traders of the 7th and 8th centuries in the Indian Ocean. The earliest form of opium, expressly described by any Western writer, is the *mekônion* of Theophrastus [d. B.C. 287], an inspissated extract of the whole plant, such as the *pharmakon nêpenthês* probably was, and it is clear from Pliny that this *mekônion*, and similar opiate extracts, were made from a red poppy, as a spurious opium still is in the Himalayas and China, as well as from the true opium poppy, *P. somniferum*, with which the Romans had already become acquainted, when Pliny [A.D. 24-79] wrote. Dioscondes [A.D. 77] is the first to distinguish the opium, prepared from the *kôdeia* or capsule of *P. somniferum*, from *mekônion*, and down to the 15th century "meconium," was still distinguished from true opium, the "opium Thebaicum" of the time. I have not the slightest doubt myself of primitive opium, *i.e.*, *parmakon nêpenthês*, and *mekônion* having originated in Central Asia, the known home of the wild form of *P. somniferum*; and it is very suggestive to note in this connection that the Hebrew word *rosh*, translated in our A.V. of the Bible by "gall" (Deut. xxix. 18, and xxxii. 32-3; Psalms, lxix. 21; and Jeremiah viii. 14, ix. 15, and xxiii. 15; and Lamentations iii. 19) is not "gall," *i.e.*, "bile," but a plant, as is indicated by the Hosea x. 4, where *rosh* is translated "hemlock," and that plant one yielding a nauseously bitter soporific decoction, and, undoubtedly, as every reader of the last text referred to who has travelled in the Holy Land will recognise, the red flowering *P. arenarium*. Also the very word *rosh* recalls the letter "r," in *roia*, the pomegranate; *roias*, "the pomegranate red poppy;" *eruthra*, "ruber," "robigo," *rouge*, and red; and also in the Sanskrit *rudhira*, "blood." In the "Song of Moses" it is evident that the wine of Palestine is contrasted with the accursed beverage, an opiate one as I conceive, of the neighbouring Egyptian and other heathen. With reference to the passage in the Psalms, the Gospel according to St. Matthew says (xxxii. 34) :—"They gave Him vinegar to drink, mingled with gall," the Greek word here meaning bile; and the Gospel according to St. Mark (xv. 23) :—"And gave Him to drink wine mingled with myrrh," that is, with *esmurnesmenon*, which was probably some soporific syrup of myrrh similar to those the Greeks and Romans were in the habit of administering in the form of various portions to numb the sensibility of persons condemned to death. Such probably was the *diacodion* of Pliny, a "brose" prepared by stirring a decoction of 120 heads of the poppy *aphron*, thickened with frankincense and gum acacia, and flavoured with saffron, into one sextarius of raisin wine of Crete. I need add nothing to what Mr. George Batten has said on the modern history of opium; and from the authorities I have cited in the third edition of my "Report on the Old Records of the India-office," and independently quoted in the article on "Opium," recently reprinted as a Parliamentary paper from Dr. George Watt's monumental "Dictionary of the Economic Products of India," it is

now abundantly clear that from the 15th century true opium has been grown and manufactured in India and China, and continuously exported from Western India and Bengal. In India, its production was the monopoly of the Great Mogul, until 1757, when, as one of the fruits of Clive's victory at Plassey, it passed into the hands of the East India Company. This sufficiently disposes of the charge, as Mr. Donald Matheson admitted, in July last, and which every reader of "Robinson Crusoe" (see *St. James's Gazette*, 14th May last) should know to be untrue, that Warren Hastings created the monopoly, and originated the trade in the drug with China. I myself harbour a suspicion that the Chinese have always habitually used some sort of papaverous "opiate." The artistic elaboration of the opium pipe in the extreme west of China, bordering on Burmah and Assam, is to me a direct suggestion of such a suspicion. It may have originated in a pre-existing pipe for smoking some preparation of the hemp plant, which, like the opium poppy, is indigenous to Middle Asia; but it could not have originated, as has been suggested, in the smoking of tobacco, as this plant, which is a native of America, was not introduced into China until the 17th century. And there is the fact of the cultivation in Nepaul, Jammu, and elsewhere in the Himalayas, of a red poppy with black seeds, for the preparation of a crude opium; and that, to the present day, this opium is exported from these States in considerable quantities to the hinter-Chinese provinces of Yarkand, Khoten, and Aksu. And I have the further suspicion that it was the Buddhists who, from the sub-Himalayan cradle of their religion in Eastern Bengal, carried the use of this Himalayan crude opium all over India, and introduced its cultivation, with that of the tea shrub, through the passes of the Himalayas, into the western provinces of China proper. And is not this, probably, the true explanation of the sudden conversion of the whole population of ancient India, except the Rajputs, from the use of various intoxicants to total abstinence from them, ever since the date of the rise of Buddhism in India. In his "Vicissitudes of Aryan Civilisation in India," Mr. M. M. Kunte (Bombay, 1880), has conclusively demonstrated that the Vedic Hindus, like all other Aryan races, were voracious eaters of beef, and inordinate drinkers of wine or beer; and an entire *mandala* of the Rig Veda is devoted to the praise of their favourite intoxicant, *soma*, which probably included beers and wines brewed from various sources, such as the date, vine, &c., flavoured, or perhaps fermented with the twigs of some such plant as the *soma-lata* of modern India, *Sarcostemma brachystigma*. In the Hindu mythology, Indra, beside the other things he personifies, is also the "divine afflatus" produced in him who drinks the "sacred *soma*." Drunkenness has been regarded as of this supernal significance in the primitive faith of all nations, as it still is among savage races. Undoubtedly mankind have, in the mysterious processes of Providence, been greatly indebted to drunkenness as well as to dreams, for many of their most exalted spiritual conceptions, and this is, in part, the explanation of the sacramental position held by strong drinks and other narcotics, such as tobacco, &c., in the religious rites of every country of the world, savage and civilised [cf. Deut. xiv. 26]. At all events in India the whole economy of Hindu life is based on the daily *soma* sacrifice; but ever since the advent of Buddhism the offering of flowers and fruits, and in rare instances the ceremonial drinking of a harmless *soma*, infused from the twigs of *S. brachystigma*, has been substituted for beef and wine, or beer. Only among their chivalrous Rajput leaders, who have always represented the Vedic spirit of Aryan superiority in India did the wine or beer drinking habits of the ancient Hindus survive down to the time of their suburgation by the Mahomedans, when for "the intoxicating cup" they partially substituted the true opium introduced into India by their Mahomedan conquerors. It is evident that this temperance reform was promoted among the Rajputs, by their taking to the opium then received from the Persian Gulf and Egypt; and how could the still more remarkable revolution wrought in ancient India by the Buddhists have been accomplished without the aid of some similar narcotic stimulant; and what was there at hand, saving some crude form of opium; for the Buddhists would no more have tolerated hemp than wine or beer; while, for a vegetarian population, such as the bulk of the Hindus became under the Buddhists, living within the tropics, opium was an absolutely necessary adjuvant to their daily diet. But all this is mere speculation, and I now pass on to speak of my personal observation of the habitual use of opium during my 15 years latter residence in Western India. I paid the closest attention to the subject during the whole of the years I was there, and had every kind of experience in relation to it, having at different periods been in medical charge of the Southern Mahratta Irregular Horse, the 8th Madras Cavalry, the 3rd Bombay Native Infantry, a battery of Artillery, the jail and civil station of Sholapore, and the steam frigate *Ajdaha*. Subsequently, and for the remainder of my service, I was attached to the Jamsetjee Jejeebhoy Hospital, Bombay, and was in succession Professor of Anatomy and Physiology, and of Botany and Materia Medica, at Grant Medical College. I was also a J.P. and visitor of the jails in Bombay, and the year I was sheriff I regularly visited them. Besides this, I was probably more intimately familiar with all classes of the native population than any other European of my generation, while, as an ever active journalist, I was mixed up in almost every discussion of this sort during my time in Bombay. Well, in all the experience, as here precisely detailed, and capable, therefore, of being checked at every point, I thus had of the indigenous life of Western India, I never once met with a single native suffering, or who had ever

suffered, from what is called the excessive use, or from the habitual use of opium; and, excepting cases of accidental or wilful poisoning by opium, I never knew of a single instance of death from its use. And I have never met with anyone who, in his own personal experience, has known a case of death, or of injury to health, from the habitual use of opium as practised by the people of any part of India proper.* So far as I can remember, in the printed tables used in Indian civil and military hospitals for the entry of diseases, there is no column for the "opium habit," nor for "deaths from opium." On the strength of my personal experience, I should be prepared to defy anyone to bring forward from their personal experience a single authentic record of death, or shortened life, from habitual opium eating or drinking in India. If any one can, let him, and the means of verifying his or her statement are always, within the current generation, accessible in India. On the contrary, so far as my experience goes, the healthiest populations of Western India are those distinguished for their, so stigmatised, excessive use of opium. I refer to the people of Gujerat generally, and more particularly to the people of the Kaira district, and also of the neighbouring district of Broach. As to opium smoking, it is, from my experience of it, as innocuous as smoking hay, straw, or stubble. It has not the potency of the mildest tobacco smoking, as judged by my experiments with it on myself. I have, therefore, always presumed that the morphia in "the smokable extract of opium" is all decomposed in the flame of the lamp at which the opium pipe is lighted, before the smoke from it reaches the lungs. This, however, is only a presumption; and, in one case, examined by Professor Attfield, morphia was found in the ashes of an opium-pipe used by a smoker in the East-end of London. But, be this as it may, we find in China, as in India, that nowhere are the native populations so robust, industrious, and thriving as in the principal opium-producing provinces of the Empire. It is enough to refer on this point to the report by Mr. W. Donald Spence, our Acting-Consul at Ichang, published in the Parliamentary Paper, No. 3, of 1882, page 35. Of course, I know the *in terrorem* cases to be seen in the opium dens in Bombay and elsewhere in the East. I well knew the Bombay den kept in my time by a Chinese "gentle convertite" to Christianity. It was the one den in a city with a population second, in the whole British Empire, only to that of London. Yet I never saw more than ten or twelve opium smokers there at any time—poor, lost souls, whose miserable, physical, and moral degradation and depravity it would be impossible for even descriptive reporters and sensational photographers to exaggerate. But who were they? The dregs of the lowest outcasts of the greatest emporium of trade in the Old World outside London, and the sink of all the miscellaneous roving vagabondage of the Indian Ocean. And as for the real causes of their sufferings, I will only here say that, so far as I could ever ascertain, they had nothing to do with the opium-pipe, which seemed to me to be simply the last palliative of their "disnatured torment," until enfranchised of it all by death, which generally overtook these cases of complicated and perverted nympholepsy in from three to nine months. I hold the recipe of the *chandu* sold in the Colbhat den, and it is difficult to understand how, when decomposed in the opium lamp, the stuff could have the slightest physiological effect on its smokers. I am not entitled to discuss the administrative and economical sides of the opium question; but surely those who hold that the habitual use of opium is harmful, should be the last to object to the State monopoly of the production of the drug in India. I, on the contrary, holding that its habitual consumption is essential to the health, wealth, and happiness of a vegetarian tropical people, would freely throw the cultivation and manufacture of it open to private enterprise, and raise as large a revenue from its export from India as it would bear. The whole public revenue of India might, in this way, be derived from its export, and the people of India left practically untaxed. But who are we, that we should object to the people of India and China using opium as a narcotic stimulant. You have all read in the *Times* of the 17th ult., the statement of the yearly drink bill of the United Kingdom, prepared by the Rev. Dr. Dawson Burns. It mounts up to £141,000,000, or £3 15s. per head of our highly Christian population. Sir John Hart, the Inspector-General of Chinese Customs has, in an elaborate memorandum, estimated the total sum spent on opium by "the heathen Chinee" to be, at the outside, £25,000,000; or an average of twenty pence per head. If we replaced our Christian drink by the Chinese heathen opium, our annual expenditure on the same would be but £3,150,000, instead of £141,000,000, a great saving to the pockets of British consumers; while if the Chinese could only be induced by our missionaries to give up their opium, and take—for it would come to this at last—our drink instead, their annual drink bill would be £1,125,000,000, a prodigious prospective profit to the British and other manufacturers of every denomination of strong drinks. And were the Imperial Government to force the Government of India to abolish the production and habitual use of opium in that country, an unlooked for market, of immeasurable magnitude,

* While Mr. Alexander—whose fairness in controversy, and unfailing courtesy on all occasions, I desire to warmly acknowledge—was speaking, the following extract was handed up for me to read from Sir Charles Bernard's well-known "Note," appended to Sir Charles Aitchison's Report on the "Use of Opium in Burmah":—"Neither in the gaols, nor in the opium shops, nor in the villages, save in Minlyin, did I come across actual tangible evidence of the effects of opium." To this a reply was vociferously made from the back benches that, when Sir Charles wrote the "Note," he had been only two months in Burmah. But I have since ascertained from Sir Charles Bernard that he still stands by his "Note," and to every word of the above extract.—Geo. B.

would be opened to our gin and whiskey distillers there also. Few things indeed could be more perilous than that a question so vast and intricate in its nature, and so far-reaching in its bearings, should be hurried on to the arbitrament, as is proposed, of the British constituencies at the next General Election. It is in this impatient, reckless, and suicidal manner, that not only economic, social, administrative, and political, but even literary, scientific, artistic, and religious questions are now treated in this country, until every problem of our national life is being confused by irresponsible counsels, and turned to our destruction; and from a present so oppressed by popular prejudices and passions the outlook into the future would indeed be full of humiliation and bitterness and despair, but for the support derived from the historical conviction that this world is overruled by a predetermining power which, whether the necessity of nature or the supernatural will of universal belief, directs the destinies of nations through every deviation into error and evil, to the enduring ends of truth and righteousness.

The Rev. F. Storrs - Turner:—I expected to hear a discussion of the actual position of the opium question — a discussion starting from Lord Lansdowne's reply to the anti-opium memorial—but the debate has reverted to ancient history. The anti-opium party have no fear of an appeal to history. The verdict of history has been written, the verdict of the national conscience has been pronounced, in a final and irreversible condemnation of our wicked Chinese wars. With all respect to such distinguished men as Sir Thomas Wade and Mr. Lay, who were no mean actors in that history, I venture to tell them, with the utmost confidence, that nothing which they can say will avail to alter one tittle of that verdict. Nay, more, I am bold to say to their faces, that if they could now say anything which could avail to reverse, or seriously to mitigate, that verdict, they would thereby prove themselves gravely culpable in having kept silence so long. They are not blame-worthy, because they have nothing new to tell. In this whole, sad story, from the smuggling of opium in the beginning of this century to the Chefoo Convention, there are no secrets, no inexplicable passages. It is interesting to listen to men who have helped to make history, and their personal reminiscences may correct small details, but neither of these gentlemen has told us anything of substantial importance which was not known before, partly through their own reports, partly in other ways. Mr. Lay has told us something of the arrogance, insolence, and stupidity of the Canton mandarins. But that is not news. I have said on scores of platforms that opium was not the only cause of the first war. I can show to Mr. Lay in my book, "British Opium Policy," printed in 1876, passages setting forth that side of the case, which I think he would acknowledge, do not fall short of what he has said to-day. But did Chinese pride and impracticability justify the East India Company, the British Parliament, and British merchants for their complicity in smuggling poison into China? There might have been a war if there had been no such thing as opium in existence. The war that actually took place from 1839 to 1842 began from the opium trade, and ended with extorting from the Chinese the price of the smuggled opium which they had destroyed, leaving the smuggling to go on just as before! In this brief space it is impossible to give even the slightest sketch of the history. Mr. Lay has left out almost all the important facts; he said not a word of the repeated warnings to the merchants, of their defiance of the Chinese Government and of their own superintendent, Captain Elliott, of scenes of bloodshed and violence which make one wonder that the scandalous story of wicked lawlessness did not end in a wholesale massacre of the merchants engaged in the nefarious traffic, and of the rest of the foreigners who were with them. Lin took the opium and spared their lives. You have heard from Mr. Lay, that Captain Elliott kissed the rod, and begged to be allowed to resume trade. Mr. Lay numbered Lin's refusal among his reasons to justify the war. But he did not tell you that what the Chinese wanted was a guarantee that the merchants would henceforth nevermore smuggle opium. This Elliott could not give. Why, the merchants began to smuggle again the very instant they got a fresh supply of the drug! They were resolved to continue the illegal traffic. The East India Company was continuing to prepare the drug for the smugglers. The British Government had persistently declined to interfere. Yet Mr. Lay makes it an accusation against Commissioner Lin, who had been sent from Peking with express orders to extirpate the smuggling trade, that he did not permit these opium-smugglers to have comfortable head-quarters in Canton or Macao! To Sir Thomas Wade—for whom I feel sincere respect, and, if he will permit me to say so, even affection, on account of his zealous and benevolent exertions on behalf of the Chinese famine fund, for which we pleaded side by side—I have no space to reply satisfactorily. I have ventured to remind him that in 1842, Sir Henry Pottinger, under instructions, endeavoured to induce the Chinese Government to legalise the opium trade and was repulsed. Humbled and vanquished by our arms, the Chinese Emperor is reported to have made this memorable answer:—"It is true I cannot prevent the introduction of the flowing poison; gainseeking and corrupt men will not profit and sensuality defeat my wishes; but nothing will induce me to derive a revenue from the vice and misery of my people." Sir Henry Pottinger, an honourable and humane man, as is evident from his proclamations, would, after this refusal, have put a stop to the opium smuggling if he could, but his superiors would not allow him a free hand. I entirely believe Sir Thomas Wade and Mr. Lay when they say that neither they nor Lord Elgin used menace or

force to extort the legalisation of opium; but as to the fact, the legalisation was a result of the "Arrow" war, and as to whether the Chinese felt themselves compelled or not, I would go to the Chinese for information. Prince Kung's subsequent despatch in 1869 is an expression of the Chinese feeling, which puts the matter beyond controversy. There never was an agreement negotiated on equal terms, freely and voluntarily, on both sides, between Great Britain and China, previously to the Additional Article to the Chefoo Convention, signed in London in 1885. If the evangelisation of China is the best hope for the deliverance of that mighty people from the thraldom of opium, so also the best and surest means to convert the Chinese to Christianity would be the summary and entire suppression of all opium exportation from India to China. Such an act of righteousness, of pity, of atonement, would be a stronger auxiliary to our missions than the addition of ten thousand missionaries, even though they were able to take the Han-lin degree in Peking.

Sir JOSEPH FAYRER, K.C.S.I., M.D., F.R.S.:—I regret that I was obliged to leave the meeting at such an early stage of the discussion, another engagement rendering it impossible for me to remain. I was much interested and instructed by Mr. Batten's paper upon the opium question, which was most elaborately and, as I thought, fairly stated, with, perhaps, a tendency to under estimate such evils as arise out of the abuse of opium. With the historical, political, geographical, commercial, and statistical portions of the paper my remarks are not concerned; they will refer to the important question regarding the use of opium and its influence upon the health of the population of India and China, or wherever else it may be resorted to as a habit. It is most strenuously urged by a large and influential, and, as I believe, thoroughly conscientious party, that the use of opium, either by eating or smoking, is attended with the most pernicious results, causing, sooner or later, demoralisation and destruction alike of body and mind. They seem to be of opinion that the degraded condition of the *habitués* of opium-eating or smoking houses, whether in India or China, represents the natural and, one might almost say, the inevitable results of the use of opium. Ideally, one would wish that stimulants and narcotics, such as alcohol, hemp, opium, tobacco, chloral, and sundry others of recent invention, had no existence; but, unfortunately, human nature is so constituted that it will not forego the use of these drugs, each and all of which is liable to be abused, and when so abused, produces the most degrading and pernicious effects upon the human race. One of the curses of our own country and our own race is the abuse of alcohol—the amount of disease, misery, and crime produced by it is incalculable. With any who might enter upon a crusade against this form of indulgence, which should correct the abuse and limit the use of it within reasonable bounds, I confess that I should have the greatest sympathy; but I should never expect to succeed in excluding alcohol altogether from use as food. There cannot be a doubt that, in the great cities of India, in China, and probably elsewhere in the East, the abuse of opium is carried by a certain, but a limited number, to a great extent, but to nothing like the extent to which the abuse of alcohol is carried. It is well known that, over large areas of country in India, by tens of thousands of people, opium, in moderation, is habitually used by the natives; and that they have a thorough belief in its efficiency to protect them against malarious disease; and that, under its influence, all the functions of life are better performed; that life is not shortened; and that physical and mental conditions are improved and not deteriorated. This I know to receive the support of those who know far more about the subject than I do, and I am not aware of anything to controvert it. It is said, I believe, by its opponents, that the tendency of opium-eating is ever to increase—to induce, it may be, slow, but sure degradation and destruction. I do not believe this. In the course of many years' experience in India, I have known so many who have been habitual consumers of a small quantity of opium, without in any way suffering from it, or without any tendency to increase the habit, that I am unable to agree with those who state otherwise. One of my most intimate friends—a native nobleman, with whom I frequently associated—died after the age of eighty. He was a man of remarkable intellectual, mental, and physical vigour, of wonderful powers of endurance of fatigue, a great sportsman, a spendid shot, as complete an example of a native gentleman as one could wish to see. He was an opium-eater, and consumed his two or three doses a day with unerring regularity. This he had done for many years when I became acquainted with him. He never increased the quantity, nor had he done so for several years; he showed no signs of degeneration, mental or physical, or anything suggestive of a pernicious habit. It must be in the experience of old residents in India to have met with similar cases. It seems to me that this crusade against opium, though well meant, is not reasonable. It is as unfair to argue from the *habitués* of opium-smoking houses, as it is from the frequenters of gin palaces and other haunts where the most degraded forms of alcoholic abuse may be met with in our own country. Both, in extreme cases, are an evil; but the moderate use either of alcohol or opium must be left to the discretion of those who feel called upon to take them. There is another drug which is also in frequent use in India, the hemp (*cannabis*), which is infinitely worse than opium. I find no objection taken to this drug by the anti-opium party. I can see no medical ground that would justify violent interference with the custom in question. Control and limit the abuse of opium, but to interfere with and suppress it altogether seems to me unjustifiable.

I know no reason why opium should be interfered with and alcohol be exempt. The evils of the one are far inferior to the evils of the other, and the moderate use of both—as I have said—should be left to the discretion of those who want them. It seems to me to be clearly proved that the moderate use of opium is not attended with the evil results ascribed to it, though, as with alcohol, a certain number of persons will abuse it. I repeat, therefore, that on medical grounds I see no reasons for advocating the abrogation of the present regulations concerning opium in India. I confine myself entirely to the medical aspect. Other and convincing reasons for maintaining them have been ably advocated in the exhaustive paper to which I am now referring.

Mr. MAURICE GREGORY (Editor, *Banner of Asia*, Bombay):—Mr. Batten has stated that the gross profits of the Bengal poppy cultivators are Rs. 5 per seer of opium. Out of this the heavy Government advances have to be repaid. Sir Charles Aitcheson shows on page 40 of Blue-book just issued on "Opium" (C.—6562 of 1892), that the nett profit of the cultivators at the time of writing was 4 as. 8 pies per seer of opium produced. For each seer the Government obtained Rs. 48 8 as. In other words the Government allows the cultivators 1½d. out of every £ of its own profits. In like manner, on every chest of opium exported from Malwa, the Government levies Rs. 600, which only permits the rajahs to levy an average duty of Rs. 10. In other words the rajahs obtain 2½d. for every £ levied by the Imperial Government. The fact should be emphasised that the opium prepared by the British Government in India is almost entirely used for purposes of debauch. John Dudgeon, M.D., Surgeon to the Peking Hospital, late Honorary Physician to her Majesty's Ambassador at Pekin, Professor of Anatomy in the Tieng Weng Kwan, speaking of the sexual effects of the drug, as prepared for smoking by the Indian Government, says:—"Its moderate use causes, for a time, a feeling of renewed vigour, and perfect present enjoyment; and this is one of the chief reasons assigned for the commencement of, and addition to the habit. Ultimately, the reverse condition ensues, and the poor smoker is practically impotent" (page 576 "Transactions Social Science Association," Liverpool Meeting, 1876). Similar evidence is given by Dr. Osgood, of the Foochow Medical Missionary Hospital (experience of 1,100 cases of opium-smokers); Dr. James Watson, of Newchang, in "Medical Reports," published by order of the Inspector-General of Customs; J. Kenneth Mackenzie, L.R.C.P., M.R.C.S., late of the Hankow Hospital, and of Tientsin, where a hospital was built for him by the great Chinese statesman, Li Hung Chang; George Shearer, M.D., F.L.S.; James Galt, F.R.C.S. and L.R.C.P., Edin., seven years in charge of the Opium Refuge, Hangchow; and many others. Dr. A. G. Reid, of the Chinese Imperial Customs Service, of Hankow, speaking of the worse than bestial degradation of the opium smoker, says that he will even sell his wife in order to obtain the drug. Dr. Ayres, colonial surgeon, of Hong Kong, says that "opium-eating is a terrible vice most difficult to cure, and showing rapidly very marked constitutional effects in the consumer." That these constitutional effects are the same as in opium-smoking is proved from the evidence of William Huntley, M.B., C.M., of Nusserabad, Rajputana, who has made exhaustive investigations into this matter. Writing in the "United Presbyterian Magazine" for December, 1890, Dr. Huntley says:—"For those between the ages of 20 and 40 there is an inducement to opium-eating which need here only be mentioned in order that men may honestly know the character of the drug we are dealing with. The temptation for the great majority of those who are in the prime of manhood is expressed in one word—*lust*. Comment is unnecessary." The leaders of the anti-opium party in England wished to be spared the necessity of bringing this awful aspect of the opium question before the British public; but they will be forced to do so if the supporters of the opium traffic continue their present tactics.

Surgeon-General Sir WILLIAM MOORE, K.C.I.E.:—It appears to me, that the vital point on which all others hinge is the question whether opium is or is not the very injurious agent which it has been asserted to be. For the last twenty-five years I have studied this question among habitual opium consumers, and on the principle of experimenting on the vile body I have used opium myself. I confidently assert that opium is not the deadly agent which it has been painted; and that climate, creed, habits, and customs, renders it almost a necessity for Eastern races. No one denies that the active principles of opium are poisonous, but so are the alkaloids of other things in daily use—tea and coffee, for instance. And so is alcohol, if taken in excess. But the vast majority of opium users do not exceed, any more than the great majority of ourselves taking fermented drinks. I have also to assert that no organic disease is caused by opium, while alcohol, as is well known, causes many organic affections, and in the most important organs of the body. Only two or three days back, Lord Herschell asked for a Parliamentary Committee to inquire into the best mode of dealing with habitual drunkards. It would I think, be better if the anti-opiumists combated drunkenness here, instead of the use of opium abroad, amongst people who, as he remarked before, are impelled to the use of opium by climate, creed, and long custom. And it would certainly be more in accordance with rectitude if the anti-opiumists refrained from sensational, exaggerated, and often untruthful statements, such as for example, that opium is destroying the Chinese nation; that the use of opium accounts for pauperism among the

Chinese; that smoking opium is more deleterious than eating it; that the maladies met with in opium shops are the result of opium; that opium prevents missionary success; that every one using opium goes from bad to worse; that the cultivation of opium in India takes up so much ground there is not enough left for cereals, and so famines occur; that if the Indian supply ceased, opium consumption would be stopped in China; that Indian cultivators are forced to grow opium; that Indian princes on whose territory opium is grown would gladly abandon the revenue derived from this source; that no benefit can possibly be derived from the use of opium. With reference to these and many other errors of anti-opiumists, I say there is scarcely an atom of truth as a foundation. If the anti-opiumists succeeded in their endeavours to abolish the use of opium in India, excepting when prescribed by a physician, the last state of thousands of poor people in India would be worse than the first. The person suffering from want of food would not be able to appease the hungry edge of appetite by the customary dose of opium, and when scarcity or famine occur, thousands more would die than before. The person having to undergo great physical fatigue would not be able to render himself proof against it by opium, neither would he be able to share the opium with his camel or horse, which, especially before the days of railways, was a point of honour with the riders. The Rajput would not be able to offer the stirrup-cup of opium water, of which I have often partaken, to his friend, as the latter leaves before the grey of the morning, or with the rising of the moon in the evening, for a 30-mile ride over the sands of Maiwar, Têysulmeer, or Bickaneer. The opium-pipe could not be introduced as now, when, after the evening meal, it takes the place of the wine or spirits consumed in other countries. But, perhaps, the worst results would fall on the *habitués* of the opium shops. At least half the people who frequent the opium shops are suffering from some malady. Those who cast stones with such virulence and so promiscuously at these poor opium smokers, do so in ignorance, and without the grace of that test of virtue's charity. They ignorantly regard the maladies which they see in opium shops, not as diseases for the relief of which opium is taken, but as the effects of opium. Lastly, opium is frequently used as a safeguard against malarious fevers, which could not be done if a physician's prescription were required, for there is not a competent doctor in every Indian village, as there is in this country. The anti-opiumists have done quite enough to render themselves ridiculous, for they have been endeavouring to achieve an impossibility. The desire for a stimulant has existed during all ages and among all peoples, and there are certain reasons connected with climate, religion, habits, customs, why Easterns use opium. If it were possible to prevent the use of opium in India, the people would take to native liquor, or to the still more injurious preparations of the Indian hemp plant. I am quite certain, after many years close attention to the matter, that stopping the use of opium in India would in many ways do infinite harm to the people of many parts of the country. As Mr. Batten has observed, you may inflict a cruel injury on India, the extent and consequences of which you are incapable of calculating, and you will fail in anyway to benefit China. Because a comparatively few people may injure themselves by excess in opium, is no reason why the majority should be deprived of opium. If means of enjoyment are to be stopped because some people are prone to abuse them, there will soon be no means of enjoyment left to us.

Mr. E. L. OXENHAM (late British Consul in China):—Opium-smoking is, it must be remembered, purely artificial, and is not, as in the case of drinking, the abuse of a natural desire. Everyone must drink something, but no one need smoke anything. I am, however, able to confirm the statements made as to opium being a prophylactic against fever. It is so used among the people dwelling on the low lands bordering on the Yang-tze, and in the malarious island of Formosa, the coolies, who can do their twenty-five miles a day, universally smoke it, and cannot do without it. The high price of quinine makes its sale prohibitive for the poor. Outside the malarious districts the use of opium is wholly an abuse. The rich use it—not indeed, with impunity, for the "craving" for a pipe increases year by year—but with naturally less disastrous effects on the family. But opium, among the poor, works terrible havoc; in eight cases out of ten the bread-winner of the family becomes, after a few years, useless, and the support of the family devolves on the women. The historical aspect of opium trade has been dealt with by gentlemen of highest authority, but what concerns us now is the state of the case in 1892. That is, do the Chinese, who have no sinister interest in the traffic or cultivation of opium, desire the continuation of the trade now? Would a Chinese Parliament vote for such a traffic? No one with any knowledge of China would answer in affirmative. The opium is equally denounced by the Government, by the Confucian *literati*, and by the Buddhist and Taoist priesthood. Proclamations, placards, tracts, and prints issued by members of above bodies abound in every town, and denounce the deluge of "foreign mud poison" which is being poured into the empire. Do foreigners themselves like or employ opium-smokers? Do they ever knowingly engage a teacher or servant who smokes opium, and are not such *employés* invariably found inefficient? Much is made of the fact that the Chinese officials do not take effectual measures to suppress the trade and the cultivation. In the first place, both have attained such huge proportions that nothing but measures, tyrannical and bloody in a high degree, would be able to suppress even half of the existing trade; and in the second place, is it possible in a democratic

country like China for the Government officials deliberately to deprive their own countrymen of profits on an article, when profits on the same traffic are deliberately granted by treaty to foreigners. It seems to me, as regards opium, that China should be allowed to "gang its own gait," without any foreign interference, as is the case in Japan. By this means China's sense of wrong and oppression is appeased, while the love of compromise inherent in the Chinese mind may be trusted not to act injudiciously. Railways are probably the direction where lies the true salvation of China. By their aid their existing and admirable educational framework will be strengthened, revived, and improved, and the reform of the individual, insisted on by Confucius as the only real and stable foundation of national welfare, may be more nearly attained.

Surgeon Lieutenant - Colonel HENDLEY: — I understand that 5,000 medical men have signed a memorial, in which it is contended, amongst other things, that the use of opium is morally and physically debasing, and associated with many great dangers to the people of India. I have practised in the native States of Rajputana since 1871, and for more than ten years have been responsible for the medical arrangements for nearly 3,000,000 people. More than 1,000,000 new cases have been treated during that period in the dispensaries under my supervision, and I have myself seen from 100 to 200 cases of sickness every day. As the result of my experience, and in opposition to previous personal, but ignorant, prejudice, I am bound to state (1) that I have not seen life shortened by the habitual use of opium as a stimulant, but, on the contrary, I have come to the conclusion that the habitual opium eater becomes happily oblivious of most of the minor ills of life, such as bad food, irregular meals, poor clothing, and exposure to wet and cold, and that he is hardened, as it were, against many diseases, as for example, rheumatism, or those of malarious origin. (2) That it is only by the use of opium that mounted police, and messengers, or guards in Native States can perform the long journeys which are required from them for many years—in short, that without this, or some other stimulant, they would soon be useless, and life to them be not worth living. (3) That I do not recollect the occurrence of any fatal cases arising from the use of opium as an habitual stimulant. No one can deny that opium can be, and is occasionally, abused like many other good gifts, but my experience has convinced me that the evils attending the use of this drug are infinitesimal in comparison with those which, in so many cases, go with drinking spirit, wine, and the use of tobacco and even teas. Of course I have seen many cases in which opium has been taken as a poison, or in overdose by unexperienced persons. When I first went to Rajputana, I was horrified at the large quantities of opium taken by some Rajputs, and predicted fatal results, but as no such cases occurred, I have naturally changed my views. We are told that opium debases and destroys those who use it. Occasionally one sees a man who is a slave to the habit and somewhat useless in consequence, but on the other hand one of the most able natives I ever saw, took daily a dose of opium as large as a billiard-ball. As not uninteresting in connection with the prophylactic uses of opium, I may refer to Mr. Strez's observations many years ago, that a large dose of opium will protect againist the ill-results of exposure to wet and cold. For example, a drachm of laudanum taken by a traveller on the outside of a coach in a storm would enable him to journey without fear of being chilled, or of getting pneumonia even if he became wet through. It has been stated that opium cannot be given up without fearful agony. I have frequently stopped its use at once, without ill results, and with far less fear of evil then when ordering alcohol to be given up. I would not hesitate for a moment to substitute the opium for the spirit-drinking habit, on the grounds that the latter is destructive to body and soul, shortens life, leads to far more family misery, and to terrible crimes, and is much more likely to lead others astray by imitation. In short, the drunkard is a nuisance and danger to himself and all around him; while the opium-eater, only in rare cases—at all events, in India—hurts himself alone, or only indirectly, by spending perhaps an unfair share of his earnings, injures his family. In China, he is said sometimes to sell his wife; but surely this is the fault of the law. An English drunkard beats her, which is as bad, and would sell her if he could; indeed, I believe he has done as much in some mining districts. It is highly probable that any injury done to families, by heavy expenditure in opium, has been compensated to them by its prophylactic value, which has preserved valuable lives. Opium does not fill Indian lunatic asylums; Indian hemp and alcohol do this. If opium were increasingly injurious, the population would have diminished, instead of multiplying enormously. My remarks relate to opium-eating; but there is evidence to show that opium-smoking is less dangerous, as, in the latter case, the alkaloids are not absorbed. A very distinguished authority on drugs has referred me to a paper in the "Journal of the Chemical Society" for 1871, by Vohl and Eulenberg, on the "Physiological Action of Tobacco," in which it is stated that the action of that drug, when used as a narcotic, is due to pyridine and picoline bases, and that there is no nicotine in tobacco smoke; so of opium when smoked, the action is due not to the alkaloids but to the bases which it contains. The memorial goes on to say that the cultivation of the poppy may be prohibited in British territory and in the native States, and that opium may be sold by druggists under the strict regulations now in force in England. What are these regulations? Strict regulations exist it is true, yet as "Hygiene" shows they are openly violated under the Government patent stamp. To use a favourite anti-

opiumist argument, every ounce of chlorodyne contains 12 doses of morphia, 36 doses of chloroform, some Indian hemp, and sometimes 6 doses of prussic acid. Yet one young woman actually bought from a West-end druggist, in one fortnight, 42 ounces of chlorodyne, and a man regularly took a bottle a day. Only last Monday a jury strongly condemned the sale of a large quantity of opium which had been supplied to a clergyman who afterwards committed suicide. Another druggist told me that private persons constantly bought and consumed dangerous quantities of antipyrine. The soothing syrups and powders which are given so freely to children contain opium in unknown quantities. Surely it is better to give the drug undisguised as Indian mothers do. Are restrictions such as I have indicated those to be enforced in India? The native of India uses many stimulants. The respectable man most frequently takes opium because with Mohamedans and some Hindus wine is unlawful. The lower classes drink spirit and use many drugs, the worst of which are the preparations of Indian hemp. I see many broken-down Sepoys, all of whom take a stimulant to drown care and hardship, but they live on, unshortened lives. I think, perhaps, that *pâu* amongst the rich is responsible for as much diseaes and trouble as opium. Now as regards native States, the prohibition of the growth of the poppy would involve gross breach of treaty, or the re-establishment of the Customs lines with all its difficulties, that is to say, if we only taxed the opium manufactured in those States, for I do not think it would be possible to prevent its export, certainly not from ports in native States. To attempt to stop the cultivation of the poppy in India, or to prevent the use of the drug altogether, seems to me somewhat as though we should try to force a British colony to give up the use of, and cease to grow tobacco, which if used to excess, some of us believe to be as harmful, and certainly more offensive than opium. As we do not dare to do this, is it not cowardly to treat India on the opium question in a way that we are excluded from doing towards other parts of the Empire. The excessive use of alcohol, opium, tea, or any stimulant certainly demands all opposition we can give, and I think that if anti-opiumists would teach moderation in all things, they would do good; and perhaps, I might add, that they can hardly expect to succeed in this, or any other question, unless they cease to abuse officials, who, after all, are as likely to be actuated by good motives as themselves. Some of the remarks made at page 12 of a pamphlet, entitled "The Poppy Plague in India," are such as would disgrace the most abandoned opium-eater. The map attached to the same publication, and the remarks as to dose which follow, are most misleading, and the deductions as to poisoning the population untrue. The Anti-Opium Committee have also published a letter which was sent to over 40,000 ministers. I think it was rather insulting to the education and intelligence of these ministers to state that the Chinese belonged to the "race by whose hands God wrote his Holy Book; the race that produced the great characters of sacred history, the patriarchs, the prophets, and the first martyrs of the Cross," yet this is what the letter does state.

Dr. J. L. Maxwell:—The reader of the paper has emphasised two points—one, the blamelessness, first and last, of our opium relations with China; the other, the comparative harmlessness of the drug. I want to say a word or two on each of these points. With regard to the first, I should like the following questions answered:—(1.) Is it or is it not true that, on the occasion of the first large venture in opium to China by Warren Hastings, the then Governor-General, the supercargoes at Canton wrote to Calcutta:—"The importation of opium being strongly prohibited by the Chinese Government, and a business altogether new to us, it was necessary to take our measures with the utmost caution?" (2.) Is it the case or not that the Court of Directors sharply rebuked the Governor-General in following terms:—"Under any circumstances it is beneath the Company to be engaged in such a clandestine trade; we therefore hereby positively prohibit any more opium being sent to China on the Company's account?" If I am right in asserting that both of these questions must be answered in the affirmative, is it not our part as honest men to acknowledge that our opium trade with China in the form which it then assumed, and in which it was continued, was distinctly an unrighteous trade? Passing to the first opium war, I should like to ask whether, for at least four months before Commissioner Lin's *coup de main*, the Chinese Government had been able so effectually to block the trade that it was in a state of thorough stagnation, and whether, having succeeded so far, it would uot have been sheer folly on Lin's part to allow of the standing menace of a large opium fleet in Chinese waters? I put this question, not because I do not fully admit Sir Thomas Wade's hearty condemnation of the haughty and contemptuous behaviour of the Chinese authorities to Lord Napier and his successors, but to make perfectly plain that the Chinese Government were in earnest, that our Commissioner and the merchants had received long warning, and that it is impossible for us to put ourselves into the position of the Chinese, and not feel that we ourselves would have acted as Lin did. Are we not justified in saying that the first opium war, whatever the faults of some of Lin's methods, was a cruel injustice? I shall not attempt to discuss the methods by which Lord Clarendon's instructions to Lord Elgin, in 1858, about the legalisation of the opium trade were carried out. I accept the statements of the Secretaries that the legalising proposals came from the Chinese side, and I accept also the testimony of our Plenipotentiary that all we then gained was extorted from the fear of the Chinese, that

is to say, that the proposals of the Chinese were the natural outcome of their submission to the adverse decision of arms. But what I should like to know with regard to the entire righteousness of our action in that matter is this (1) who suggested the provision of the Tien-tsn Treaty, that in the revision of the tariff once in ten years, there should be no revision of the opium tariff? (2) If we were so exceedingly careful and innocent as to opium legalisation, why so dreadfully hardhearted to China's appeal through Sir Rutherford Alcock in 1869? (3) If China and China only had declined the opium portion of the Tien-tsn Treaty, what possible explanation can there be of the many years delay in ratifying the Chinese *quid pro quo* of the Chefoo Convention? and (4) if we are the never-failingly righteous and innocent people in our Chinese relations, which Mr. Batten claims to be our character, what possible meaning has the clause in the Chefoo Convention, which forbids China to think of raising the tax on Indian opium till she has taxed her home-grown opium to the same extent? Some of us are sick of hearing that China is free. With such a clause as that how can she be free? Let us try on such a policy with the United States or with France before we talk of China's freedom. We dare to ask the entire repudiaton of that clause. It is a scandal on our name. With regard to the second point, I desire earnestly to deny the comparative harmlessness of the drug, and to assert that it is of such a character that it should not be regarded as a legal or proper article of commerce except for medical purposes. There is, in the action of the Indian Government itself, a *primâ facie* evidence that it recognises its hurtful and demoralising power. It has steadily and wisely refused to permit free cultivation, and it has done so, on its own showing, because it would lead to great demoralisation. We have the highest Indian authority for believing that when opium was freely grown in Assam, it led to such a condition of things as affected not only the land revenue, and that very seriously, but as threatened the continued existence of the people. The Indian Government put down, with a strong hand, the free cultivation in Assam, and it did right. It is therefore idle, and worse than idle, to talk lightly of the pernicious effects of opium. A whole century of limited areas of cultivation, and of boasts again and again repeated, that these limited areas aimed at the preservation of the people and to prevent the spread of the opium habit in India, shows unmistakably that the Indian Government recognises that there is attaching to this drug, and to its use for other than medical purposes, elements of grave danger. The question is not one of danger, but of the measure of restraint in view of that danger. Now, what I assert is that the position of the Indian Government is self-contradictory. On the ground of experience, it puts down free cultivation in Assam because it is destructive, but it does not hesitate, on the one hand, to pour into China what it believes to be associated in its use with grave danger, while, on the other, it deliberately, for the sake of the revenue from China, exposes a vast army of its own people to all the dangers of free cultivation, to the allurements, on the one side, of a fascinating vice, and to the demoralisation, on the other, produced by the ever present temptation to smuggle one of the most easily smuggled drugs, and to add to the scanty receipts from Government the richer proceeds of illicit commerce. The million of acres required for the China trade is a perpetual source of mischief to a million of cultivators, and, through them, to how many more, and is a menace of the gravest character to the whole Indian Empire. But I pass to my final word on this subject of the pernicious influence of the drug. There are three classes of men, whose voices are now raised upon this topic. There is the official class of India; there are the native populations affected by the habit and its dangers; and there is the medical profession, at home and in the East. Mr. Batten says, of the first, that not a single Englishman, who has been responsible for the well-being of India, has ever suggested the prohibition of the cultivation of the poppy. Be it so; but what of the use of the drug? Are the names of Aitchison and Mackenzie, and of their co-administrators in Burma, of so slight a value. Have there not been, in the history of Indian administration, men like Sir George Tucker, who have used words of condemnation of the whole system as emphatic as any that the promoters of the present movement have ever used. What I desire especially to say about the whole class of officials—many of them high in office—and I say it with entire respect to them, and thankfulness for the much we owe to them in the administration of a vast Empire—is this, that, on a question affecting the physical and moral well-being of opium *habitués*, it is impossible for them to judge, with the accuracy which is to be expected, either from the natives themselves, or from the medical men who have to deal with them. What do the natives of India say? The Burmese population has spoken in unmistakable terms of utter condemnation. What do the Chinese say? It suits some to decry such evidence; but there is no mistaking the fact that, since Englishmen have come into close contact with the Chinese, the universal testimony, even of the smokers themselves, has been that the habit is, physically and morally, degrading. What do the Rajput opium-eaters say—those wonderful men, who are the stalwart men of India? There is only one carefully and deliberately made series of examinations on the subject, that of a hundred cases of opium eaters at Nusserabad by Dr. W. Huntley. And his testimony is that it was with the utmost difficulty that any single Rajput could be got to acknowledge the habit. Every one was ashamed to confess it. And what do medical men east and west say? First, there is the testimony of 5,300 medical men in this country strongly condemnatory of the trade. Not a few of these have had experience in the East. Second, there is the testimony of the whole medical body,

numbering over 100, which stands in closest relation with the Chinese in all or most of its provinces, and they are one in their condemnation of the habitual use of opium as physically, and morally, and socially a curse. As more than a thousand opium-smokers have passed through my own hands in connection with the habit, I venture to say the same. And third, I hold in my hands a memorial to the House of Commons, signed by over 50 of the qualified medical practitioners of Bombay, earnestly craving the assimilation of the Indian to the English law in respect of opium, and speaking in the strongest terms of the pernicious influences of the habitual use of the drug. Surely all this body of testimony is worthy the careful consideration of those who care not only for the national honour but for the best interests of their fellow-men.

Mr. M. M. Bhownaggree:—The subject of Mr. Batten's excellent paper has been so exhaustively discussed by this meeting, by men whose opinions are entitled to the greatest weight, that I do not feel justified in doing more than briefly touching on that part of it which might be termed its Indian aspect. Even in reference to that part of the subject, such main points as the effect of opium cultivation on the revenues of India, and of its consumption on the opium-eating communities there, have been so fully treated by persons who have for years studied those matters, that I do not feel called upon to say any more than that I fully concur in the views set forth in the paper. I have lived all my life in Bombay, and have intimate acquaintance with parts of Gujarat, especially the Province of Kattyawar, those tracts in Western India where opium is chiefly consumed, and I am prepared to avow that I have never known opium-eating to have spread to any considerable extent, nor the evil arising from that habit to have attained any marked proportions. If legislative interference with regard to one kind of intoxicants more than another is at all required for India, it is with respect to European wines and spirits. While opium-eating might be said to be confined to a mere handful of men here and there, in India the consumption of wines and spirits of European manufacture is gaining ground with such rapidity even among those larger communities which are prohibited by their religion from the use of alcohol, that it is become a crying evil; so that if the anti-opiumites and philanthropic missionaries who are pursuing the shadow of the opium ghost would divert their attention to the importation of spirituous liquors from Europe, they might do some real good in the long run. But perhaps the powerful interest which protects the breweries and distilleries of this and neighbouring countries offers them no inducement in that direction. On the other hand, the further impoverishment of the revenues of India, a considerable portion of which is now raised by a duty levied on the salt which the very poorest of the poor have to eat as a necessary of life, seems to be too trivial a matter for the consideration of these philanthropic friends of India! That India does not need or desire any interference in regard to the growth and consumption of opium, is amply proved by the fact that there has never been any agitation there on the subject. I am aware there have been recently a few meetings held, and some desultory memorials addressed, in the spirit of the agitation raised here, but they are too transparently the work of the agents of this agitation itself to merit any serious consideration as being the voice of India. I crave permission to refute one staple argument incessantly urged by the other side, viz., that the British Government is enforcing the cultivation of opium on large tracts of land in India, and, by implication, the consumption of that drug on the people. This, I need scarcely say, is a monstrous misrepresentation. Government has, over a long number of years, been only trying to reduce the number of the opium-growing territories, and I have in my possession a thick volume, containing the authoritative history of the controversy between it and the whole of the States of the large province of Kattyawar, in which the latter have contended for the last thirty odd years, for the right of growing opium. I am sorry to say that that right has not yet been conceded. But the energy with which the Chiefs of that province have pursued this matter, and the argument they employ—that the denial of such right is harmful to the interests of their subjects, and a source of irritation among them, is an answer of no small significance to those who are responsible for the misrepresentation. As regards the present agitation, I crave leave to relate a little information I have gathered about it. I went to a meeting held last night at the Fraser-street Mission-hall at Chiswick, where a Mrs. Lynn was announced to deliver a lecture on opium, illustrated by lantern slides. In the course of the lecture, which was ably delivered, but full of gross misrepresentations, of the lime-light slides exhibited, two represented a few Chinamen lying wounded or dead, with a due proportion of blood daubed on their bodies:—these, the fair lecturer explained, were the men "murdered" by the Queen's murderers, who, she further explained, were British soldiers, in that great British crime, the Chinese war. She paused here to exhort her hearers not to let a son of theirs be enrolled in the British Army! Another of the plates represented an opium warehouse in India, and yet another a retail shop; these, the lecturer explained, were her Majesty's poison stores. A hymn was sung later on at the meeting, in which it was said that "the influence of English rule on India had been baneful." At the end of the lecture the chairman drew out from his pocket a printed memorial, stating that he, and he hoped the audience, were satisfied that the opium policy of the British Government needed immediate annihilation, and therefore asked them to empower him to sign the memorial which contained a prayer to that effect, on behalf of what he called the "public meet

ing." I might state here that, in the usual speech introducing the lecturer, the chairman had distinctly stated that he knew nothing about the opium question, and that "he did not want to betray his ignorance" by speaking at length. After the memorial was read, or rather mumbled over, I thought it my duty, as a British subject, knowing something about India, and, as a resident of Chiswick, to ask if I might be allowed to speak before the vote of the audience was taken on the memorial. I told the chairman that the lecture was full of exaggerations and mis-statements; that all the arguments employed were one-sided. The Chairman said the meeting was only for a lecture, and not for discussion, and the paper before it was only a memorial, not a petition; and that therefore no discussion was expected or allowable. I bowed to the decision, only pointing out that, whatever it was—memorial or petition—it was not fair to spring such a paper on the audience, and to pass it without hearing remarks offered on the other side. The chairman, however, hurriedly called for the vote, and declared the memorial "passed unanimously." Thus the voice of the public of Chiswick was added last night to the unanimous voice of all parts of Great Britain, calling upon the responsible ministers of the Crown to stop in India the growth, consumption, and trade of the poison "which," to use the fair lecturer's reiterated phrase, "the Christian Queen of England was manufacturing to kill not only her own subjects with, but those of the heathen Emperor of China."

Mr. J. FERGUSON (Editor *Ceylon Observer*), said:—I appear as one who sympathises to a large extent with the work of those who desire to check the consumption of, and limit, if not suppress, the traffic in opium. But I would deprecate as harmful to that very cause, and as showing a dangerous example to our native fellow-subjects, the circulation of exaggerated, highly-coloured stories based, it may be, on the off-hand statements of natives who do not know what is to be made of their so-called facts, and who certainly do not realise the force of the language sometimes used by them. In Ceylon, so far as we know, there is no cultivation of the poppy for opium, and the importation of the article, so far as the Customs' returns show, has not greatly increased for the last thirty years. But I hold in my hand a pamphlet entitled "The Truth upon a Momentous Subject: an appeal to Christian Electors," which contains on one page a note respecting Ceylon which has astounded me, in what is said to be a native gentleman's testimony respecting the "plague" of opium. He speaks of villages being "decimated," and of many of his own relations being ruined by Government opium. Now, I can only say that this is news to me, although I have been thirty years in Ceylon, and all that time a careful reader of mission reports, and, as far as possible, of native news. I am certain, in fact, that the story is a great exaggeration, and I doubt if the native understood the meaning of "decimated." I think, in a matter of this kind, the philanthropists of England should not treat their fellow-countrymen in the East, the Civil servants of India and Ceylon, as the enemies, but as the friends of the natives, and as men who, with few exceptions, are anxious to do what is best for their welfare. But I wish, more particularly, to mention a fact not at all so widely known as it ought to be among the home public. The craving for opium among the people of India and China, in the first instance, is mainly, if not entirely, caused by the prevalence of malarial fever of a depressing type. This is the case in Southern China, in many parts of India (Lower Assam included), and even in the fen districts of England where opium is used, and the best possible remedy for the fever and the true cure for the craving for opium, is found in one of the greatest blessings ever provided for such people in cheap quinine. This is due first to the enterprise of the Indian Government in employing Mr. Clements Markham to get Cinchona plants from Peru, and afterwards in cultivating gardens for them, and to the energy of Ceylon and Indian planters in growing the valuable tree for its bark so freely that quinine in 20 years has gone down from 16s. to below 1s. per ounce. Now, in 1887, I urged on the Anti-Opium Society to try and do something to make known the value of cheap quinine to the millions of China as a most practical means of checking the demand for opium, by curing fever and removing the craving for the "black smoke poison" or laudanum. There is one word more, let me remind you that Mr. Goschen was quite right when he stated in the House of Commons that if the consumers of tea confine themselves to the superior India and Ceylon products (leaving the often uncleanly prepared or adulterated China teas alone) they will do much to discourage and destroy the trade in Indian opium, for it is with the money that the Chinese get for their tea that they are able to buy this luxury of opium.

Surgeon-General JOHN MURRAY, formerly Inspector-General of Hospitals, Bengal:—I was for some years residency surgeon at Indore, the channel through which all the Malwa opium passes to Bombay, and I occasionally acted as opium agent. I took great interest in investigating the cultivation, preparation, and adulteration of the drug, and its use among the natives. I was informed that it added to the comfort and enjoyment of life, without injuring the health, if proper food was used; but if from misfortune the supply of food fell short, people were in the habit of increasing the quantity of opium to relieve the feeling of want, until they destroyed the power of digestion, obscured their intellect, and became the debased victims of debauchery of the type described by the anti-opiumists. On the whole, two points stand out quite clearly as the result of my experience. First, that the use of opium by those who can afford it was

as general in Rajputana as the use of port wine or whiskey was in this couutry in my younger days. Secondly, that besides its invaluable use in medicine, of which this is hardly the place to speak of at length, it has a real place among the gifts of God for brightening and cheering life in a hot or unhealthy climate. It is, in fact, against the abuse, and not the use of opium, that we have, as friends of the race, to fight.

Brigade Surgeon R. PRINGLE: — The value of opium, from a pro-opium point of view, may be summed up in the following, taken from a long article in the *Times* of the 21st March, written apparently with the object of pointing out the climate and geographical lines on which it was of the utmost importance the discussion on Mr. Batten's paper should be carried on. "There is the clearest medical evidence that the general and moderate use of opium by a deltaic population, such as that of Orissa, is an unconscious safeguard—the result of centuries of practical experience—against the endemic diseases of the delta." If it were possible to prove this statement, then the whole position of the opium question would be entirely changed; but I differ *in toto* from this view of the case, and do so from my own knowledge and experience of these endemic diseases in the very delta selected, in which I served as medical officer from the end of 1854 to 1862, first as Civil Surgeon of Juggernauth or Pooree, and then as Civil Medical Officer of Cuttack. This experience was gathered from the salt lands of the Chilka Lake (the most malarious spot on earth, if judged by the victims), and the delta of the Mahanuddy (or great river), to the jungles of the Orissa hills. I consider this statement regarding the beneficial effects of even moderate habitual indulgence in opium as absolutely unsupported by carefully considered facts, as far as my experience went, and cinchona, or "fever medicine" as it was called, in any of its preparations, and in the smallest quantity, was greedily preferred by the natives to opium; indeed as a febrifuge, or prophylactic from fever, I never once, in thirty years' Indian service, was asked for opium as a "fever medicine," and I studied the subject of malarial fever, as much as any medical officer of my length of service in India. For the supporters of the pro-opium medical policy to be consistent on this point, they must be prepared to explain how the poor Burman, in his deltaic country on the east of the Bay of Bengal, differs from the Ooryiah under precisely similar geographical and climatic conditions on the west, to such an extent, that what is viewed as a necessity for the Ooryiah, is such a perniciously dangerous drug for the Burman, that in the Burman opium license the following occurs:—"Sec. 3. That he (the licensee) shall not sell these articles (opium and poppy heads) to Burmans." Again, if opium is such a necessity to secure that "unconscious safeguard" against malarious influences, I ask how the Commissioner of the Central Provinces (Sir Charles Bernard) could explain his action in taking credit to his administration for having taxed opium higher than elsewhere in India. As well tax quinine as opium, if the latter is such an important febrifuge. In explaining how opium could not, in an sense, be a febrifuge, I would point out that the drug, even according to Dr. Watt, tends to "diminish every secretion, except that of the skin;" and Sir William Moore, K.C.I.E., Surgeon-General, Bombay, who has publicly withdrawn from advocating "opium as a necessity," notwithstanding its "beneficial effects," states that he has come to the conclusion "that the only malady opium, in moderation, tends to foster, is the comparatively minor one of constipation;" and further on, in his "Errors of Anti-Opiumists," page 10, adds: "When used for a long period in large quantities, it produces a depressed and quaint hysterical condition, with tendency to diarrhœa." But this constipation is in a great measure due to defective biliary secretion, than which all who have any practical knowledge of malarial fever know of no state which is more favourable to a febrile attack, and none which tends more to a return of the disease, by laying the foundation for that most fatal complication, malarial dysentery. The Chairman, when Lieut.-Governor of the North-West Provinces and Oudh, as also Surgeon-General Cunningham, M.D., then medical adviser to the Government of India, and for 20 years practically the chief sanitary authority in India, must recollect the appalling epidemics of malarial fever which decimated the upper portion of the Mesopotamia of the Ganges and Jumnah; and surely if opium was then considered such a valuable febrifuge as it seems to be now, how was it that it was never given gratuitously, to secure that "unconscious safeguard" from the fatal malarious influences of a system of inundation mistakenly called irrigation, which I have carefully watched as divisional sanitary officer for twenty years from 1864, and seen this fatal influence steadily march from Saharanpur to Manipuri. The Chairman would recollect this artificially-produced malaria in the almost practical depopulation of Hurdvigunge and of Secundrabad, and his being nearly flooded out of his tent at Somnah, between thse places. Here was an ample field for testing the febrifuge virtues of opium; but instead of this, preparations of cinchona were gratuitously distributed, and a vast system of drainage carried out, at an enormous expense, to correct the errors of a system of unscientific irrigation, which produced a water-logging of the soil, greatly increased by a system of unscientific raised-roads, with deficient water-way across the watershed. I enter into these details because if this febrifuge vertue of opium had any real existence, and the Government had any faith in it, it was their duty to give these poor creatures some of this "unconscious safeguard," as they were suffering from the unscientific errors of their rulers, and were in no way responsible for the awful mortality in their midst. I would also draw attention to the late extension of this pestiferous system of inundation to the Deoband Mesopotamia, and

to the mortuary statistics of this district. In 1879, it would seem as if this artificially produced malarial fever had reached a climax, either in the virulence of its power, or in the debilitated condition of the population, or perhaps in both combined, but the result was appalling, for, out of a united population of 4,000,000 in four districts, nearly 500,000 died in a few months; and the very birth-rate was seriously affected next year. How was the calamity met? By a noble distribution of preparations of cinchona on the part of the Government; and the gratitude of these poor people was such, that I can never forget it; and I feel truly thankful to think I had any share in thus showing the evidence of the deep sympathy of the rulers with the ruled. Indeed, the confidence of these fever-stricken people in cinchona was so unbounded, that opium was never thought of; and this was the more remarkable, because the opium poppy had been cultivated in these districts, and in 1881-82, one of them —Alighar—actually refused the favourable opium advances to reintroduce the poppy cultivation, preferring pecuniary difficulties to the cultivation of a plant which, according to the resolution of a late Governor of Bombay in Council about that time, when protesting, on moral grounds, against its introduction into the Presidency, stated he did it on account of the "widespread corruption and demoralisation" it produced when tried in Goojerat. Comment on this is needless. The only beneficial properties connected with opium in malarial fever were anodyne and narcotic, the former in the painful rheumatic symptoms after sunset in malarious districts, and the latter in the restlessness and pain often met with in malarial dysentery; but as a prophylactic I am quite at a loss to understand how this could be advanced. The opium habit, resulting from the benefit received from the anodyne and narcotic virtues of opium as a medicine in fever, independent of its action in combination with other drugs on the skin, is, alas! too often the result of this medicinal exhibition of the drug, and is indulged in after the distressing symptoms for which the opium was first prescribed have passed away, and thus, in not a few localities in Britain opium is largely consumed now, though the malaria has disappeared before the drainage and high cultivation. Were the 5,200 medical men, who signed the declaration against all indulgence in opium, asked, in the case of their own patients suffering from the opium habit, to state the origin of the habit, few, if any, could trace it to aught else than to its having been first prescribed medically, and yet, to secure this unconscious safeguard in malarious districts, the general and moderate use of opium is recommended, without the safeguard of having been medically prescribed, to cease when no longer necessary.

Dr. GEORGE WATT, C.I.E. (Reporter on the Economic Products with the Government of India):—Mr. Batten has been pleased to characterise the chapter on opium which has appeared in my "Dictionary of the Economic Products of India" as a complete monograph on the subject. Perhaps I may be permitted to offer one or two remarks of a personal nature. In writing the article referred to, I was barred from expressing my own peculiar opinions freely, since one of the principles of the Dictionary, enjoined on myself and my collaborateurs, has uniformly been to produce a work that, as far as possible, would be impersonal and impartial. We were free to exhibit the facts available on any subject, whether these were favourable or unfavourable, to what was currently held to be the views of any party in power or the policy of the Government. In drawing up the article "Opium," I venture to think I had before me a larger selection of books, reports, and official correspondence than would be possible for any person not similarly circumstanced. Whatever defects may be found in that article are entirely attributable to me, but to have utilised all the material placed at my disposal would have entailed the publication of several opium volumes, instead of the few pages in one, which alone could be afforded. Even, therefore, had there not been abundant other reasons for the exclusion of my personal opinions on the moral and medical aspects of the opium question, I had at my disposal material of greater interest to the public. But I would desire to avail myself of this opportunity of expressing some of my personal experiences and convictions on this momentous question. Let me, therefore, say that I have now resided in India for over sixteen years, and that during that time I have travelled over the greater part of our Eastern empire, and devoted my energies almost exclusively to an investigation of the resources of that vast country. Naturally, the cultivation of the poppy, and the traffic in opium, has received a considerable share of my attention. On arrival in India, in 1873, I may say that I held very pronounced views opposed to the trade. As a medical man I naturally gave the subject of the habitual use of opium my careful consideration. But to my astonishment I searched in vain amongst the ordinary people of the country for evidence of its injurious effects. It is commonly stated, though I think incorrectly, that the natives of India do not smoke opium. Those who take what may be called larger doses, in most parts of India, eat it or drink preparations that contain it, but I think I am correct when I say that of the 5,000 to 6,000 chests used up in India annually a large portion is smoked, but not in "opium-smoking dens," nor in the special opium pipe. It is mixed with tobacco in very small proportions, and used daily without any injurious efforts whatever, or without any craving being established for an extra pull at the *huble-buble* or the *hukah*. That there are opium dens in the larger towns I am fully aware. I have visited those of Bombay, Calcutta, and Lucknow, but have seen nothing that could be compared with the drinking dens where the poor British sailors are rendered mad with the drink they

are supplied with in India. Indeed, the abuse of alcohol in Europe is a hundred times worse than the excessive consumption of opium in India. Excess in both is undoubtedly injurious, and if the one could be stopped in Europe, it would be right and proper to consider the suppression of the other in India. It would appear, however, to be useless to urge facts and figures to the consideration of theoretical enthusiasts who, having failed to secure repressive legislation in their own country, have now laid themselves open to the charge of seeking a field for their so-called philanthropy in another, the rise or fall of which is to them of less moment than personal notoriety. The question to my mind is, therefore, not one of abuse of opium and alcohol, but of the legitimate use of these luxuries. Can it be said that the consumption of opium, in the small quantities taken in India, is injurious; or, to state the issue in another aspect, is it more injurious than the moderate use of beer, wine, or spirits? To answer this argument is out of the question. I can, therefore, but add my humble opinion to that of the many able speakers who have addressed the meeting, and it is briefly that, though for years I tried to discover any evidence of injury from the moderate use of opium, I failed utterly, and now firmly believe that it is far less injurious than alcohol. But when every person whose opinion is thought worth having has recorded his views, and it is thus ascertained in which way the majority of such personal opinions tend, what have we gained? The verdict of persons not personally interested in a traffic, the total revenue of which was, in 1889-90, Rx. 928,928, or, to be absolutely safe in over rather than understating it, £1,000,000. A population of, say, 258,000,000 are to be deprived of a luxury, which they have been accustomed to for centuries, by a people who pay nearly twenty-five times as much revenue on their corresponding luxury. This is a point, I venture to think, that has not been sufficiently brought out to-night. Any person who may have taken the trouble to read the publications thrust on the public by the anti-opium agitators cannot have failed to observe how carefully the distinction is avoided between purely Indian and Chinese considerations. An illustrated pamphlet, for example, may be procured for one penny at the railway book-stalls, which is said to have been written by two Indian missionaries. We there get pictures of Indians smoking opium, and find scattered here and there, throughout the pages of that disgraceful publication, the facts and figures of the Indian and Chinese trade in such a way that it is difficult for any person not familiar with the actual facts of the case to distinguish the one from the other. The British public are told of "the manner in which Indian statistics on moral subjects are manufactured." They are treated to disjointed quotations from certain Government reports, in which it is stated that "the statistics of licenses are suggestively omitted." The writers of that pamphlet have got hold of the annual administration reports for certain provinces. They have deemed it unnecessary to procure, in connection with this purely technical discussion, the annual Excise reports. Hence the absence from one report, which they chose to consult, of a certain piece of information was by them regarded as proof that Government desired the suppression of that particular item of news. It is too ridiculous to have to allude to such wilful misrepresentations, as I have already trespassed too far. Let me, however, add very briefly that a point made much of by the anti opium missionary authors is capable of a very simple and natural explanation. They have furnished a copy of the form under which licenses are granted in India to sell opium, in which the vendor is required to sell at least a certain amount of Government opium. This fact is characterised as "a device to force the opium poisoning policy by terrorism that would have done credit to Danton, Robespierre, and Marat, the monsters of the French Revolution. It is this unprincipled and loathsome system of finance on the part of a professedly Christian Government, &c., &c." Now, the simple fact is that Government has realised how absolutely helpless it is in repressing the opium traffic. It cannot prohibit poppy culture in the territory of the native princes, indeed it cannot fully stop it in every corner of its own territory. An article that has to pay a prohibitive tax would naturally be a very profitable one could it be brought illicitly to the vendors' shop. It has, therefore, been thought one of the most powerful repressive measures to ascertain the actual consumption in each and every district. This is the course that is pursued by every merchant in the world in ascertaining supply and demand. The Government can control supply; it has to ascertain demand. Having found this out, the vendor is required to pay duty on very nearly the ascertained consumption of the district, so that little or no illicit opium can be sold by him. Any person who wishes to see the effect of Government control and repression of opium, should study the figures of production in relation to revenue. It will there be seen that while the Indian consumption has averaged 4,000 chests or so during the past twenty years, the revenue in opium consumed in India has increased from Rx. 345,918 to Rx. 928,928. Fluctuations in the license to retail, which are fully explained each year in the Excise reports, are of no more importance than that the Indian consumption was 5,605 chests in 1878-79, fell to 591 chests in 1882-83, and was 6,320 chests in 1889-90.

Mr. BATTEN, having seen proofs of the discussion and the other communications, has sent the following reply:—I will briefly refer to some of the remarks made in this discussion by gentlemen whose views are opposed to mine. To Mr. Samuel Smith I would say, that my paper was neither "official" or an "apology," except in the classical sense of a statement of reasons. To label it "an official apology"

does not constitute an answer to the facts and arguments contained in it. Mr. Smith went on to say it was "one-sided." It would be more correct to call it "other-sided." The Anti-Opium Society practically deny that there is more than one side to the question. Opium, they say, is an *unmitigated* evil, except when used purely as a medicine. It produces no benefits to anyone. I have tried to show that there is another side, and that the advantages derived from the use of opium far exceed the evils from its abuse. That there are such evils I do not deny, but they have been grossly exaggerated by the Society for the Suppression of the Opium Trade. If any habitual consumer of the drug is found to be in ill-health, or addicted to vice, it is at once assumed that his disease, or vice, is due to the habit, while the truth frequently is that they previously existed, and that recourse was had to opium to relieve the disease or to minister to the vice. I am quite content to leave to Sir Thomas Wade and Mr. Horatio Lay, than whom there could be no higher authorities, to dispose of the remarks made by Mr. Smith and others on the causes and events of the war with China. Mr. Alexander calmly assumed that the opium trade of India impoverished the people of China, but did not bring forward a single fact to prove this extraordinary contention. The only sense in which the Chinese are impoverished by the trade, is the sense in which Mr. Alexander is impoverished when he pays his grocer's bill. Surely that is no reason for suppressing grocers' shops. I have already dealt with the suggestion that India may, by substituting potatoes for poppies, avoid any loss. The English farmers, who have been driven by low prices to give up growing wheat, have not yet found much consolation in the knowledge that other crops may be grown on the land turned to pasturage. But I would ask, have the Anti-Opium Society ever attempted to estimate the value of the crop they are endeavouring to destroy? For instance, were they, or were they not, aware of the great internal or external trade amounting to not less than £3,000,000 sterling annually in poppy seed? If they did know of it, why have they concealed the fact from those to whom they have been appealing to help them in the destruction of the poppy? If they did not know of it (which I believe to be the case), how do they excuse their ignorance? I do not know which would be the more culpable, ignorance of the facts with which they profess to deal, or suppression of those facts from those whom they profess to enlighten. Mr. Alexander's assertion that Indian opium is of no better quality, but only more intoxicating than Chinese opium, is not borne out by those who have personal knowledge of the matter. Sir Thomas Wade has remarked, in one of his despatches, that when a Chinese gentleman receives a visit from another, he offers his guest a pipe of Indian opium, as a matter of course, just as an English gentleman would offer his guest a Havanna cigar, or a bottle of champagne, rather than a penny Pickwick or ginger wine. Indian opium is acknowledged to have a finer flavour and *cachet* than the China drug. It is certainly purer and freer from deleterious adulterations. To deprive the Chinese of it would be an injury to the richer classes without any benefit to the poorer. Mr. Alexander observed that Mr. Brereton, the solicitor, to whose powerful lectures I referred, had for some years the opium farmer of Hong Kong as one of his clients, and therefore had a pecuniary interest in the trade. Mr. Brereton had retired from his business as a solicitor in China when he delivered his lectures, but in any case, his interest in the maintenance of the trade in opium was surely not so strong as to throw any real discredit on his evidence. How would Mr. Alexander like to be told that nothing he said on the subject of the evils of opium could be believed, because he is secretary to a society whose *raison d'être* is to enlarge on these evils? Mr. Maurice Gregory has got out of his depth when he talks about the Government advances to the cultivators having to be repaid. They are not advances, in the nature of a loan to be repaid in money, but advances on account of the opium, to be adjusted by the delivery of the opium. For instance, a cultivator of two or three acres of poppy may receive from the Government, from time to time, during the progress of the crop, sums of money, amounting to, say, Rs. 50; if he delivers 10 seers of standard opium to the Government officer, the advance is thereby adjusted; if he delivers 40 seers, then Rs. 10 remain recoverable from him, either in cash or in opium. But this liability to repay the amounts advanced to him does not diminish his profit a single cowrie. If Mr. Gregory advances a sovereign to his baker, with the stipulation that he shall take it out in muffins, I fail to see how the baker's profit is diminished by his liability to deliver the muffins to Mr. Gregory. If the cultivator gets little or no profit from the crop, why does he take a license to cultivate it? Mr. Gregory, in his anxiety to charge the Government of India with rapacity and extortionate dealings, both with the cultivator and the Rajahs of Malwa, and thus to minimise the value of the poppy crop to them, omits to see that such a course of conduct is inconsistent with the charge made against the Government of encouraging the growth of the poppy; and that the higher the tax levied by the Government on the opium, the higher will be the price of the opium, and the greater the restrictions on its consumption. Finally, I may say that nothing in this discussion has disproved, or even attempted to disprove the mass of evidence given by persons in the best position to learn the truths—(1) that both in China and India the moderate consumption of opium, even taken daily, is not only harmless but beneficial; (2) that the great majority of the consumers in both countries are moderate consumers; (3) that the abuse or excessive use of opium is injurious, though not to the extent asserted by the Society for the Suppression of the Opium Trade, but the cases are exceptional, and cannot justify the destruction of a trade, the benefits of which far outweigh the evils.

APPLIED ART SECTION.

Tuesday, March 29th, 1892; ALFRED GILBERT, A.R.A., in the chair. The paper read was "The Decorative Uses of Sculpture," by E. ROSCOE MULLINS.

The paper and discussion will be printed in next week's *Journal.*

SIXTEENTH ORDINARY MEETING.

Wednesday, March 30, 1892; J. BIDDULPH MARTIN (Member of the Council), in the chair.

The following candidates were proposed for election as members of the Society:—

Adams, Edgar T., The Cottage, Halstead, Essex.
Archer, Edgar, Ingleside, South Norwood-park, Surrey.
Bean, Alexander Thomas, 7, Victoria-street, S.W.
Curtis, Alfred Harper, 13, South-hill Park-gardens, Hampstead, N.W.
Foster, William, M.A., Chemical Laboratory, Middlesex Hospital, Goodge-street, W.
Gott, B. S., M.A., Corinium, St. Mark's, Cheltenham.
Hills-Johnes, Lieut.-General James, K.C.B., V.C., Dolancothy, Llandilo, South Wales.
Pitt-Rivers, Lieut.-General A., Rushmore, Salisbury.
Staley, Thomas Peace, 2, Fenchurch-avenue, E.C.

The following candidates were balloted for and duly elected members of the Society:—

Corderoy, George, 19, Queen Anne's-gate, S.W.
Cowper, Joseph, Penrith.
Crossley, Arthur W., Bentcliffe-house, Accrington.
Lloyd, Edmund H., Selhurst, 8, The Avenue, Ealing, W.
Ravershaw, Henry Willock, 32, Albany-road, Ealing Dene, W.
Rotch, A. Lawrence, Readville, Massachusetts, U.S.A.
Toop, Robert, Trent-villa, Weston-road, Bournemouth.
Walker, Theodore, Glen-hall, near Leicester.
Wates, Edward A., Lingsugur, Deccan, India.

The paper read was—

FOREIGN EXCHANGE.

BY EWING MATHESON.

If some apology be necessary for bringing forward so old a theme as Foreign Exchange, it may be said that at the present time insufficient knowledge on the subject often hinders the discussion of important questions. Controversies continually arise concerning trade and foreign tariffs, which might be simplified or avoided if there were a wider acquaintance with the instruments by which international commerce is carried on. That is to say, while most business men thoroughly understand the clearing-house system of dealing with inland cheques, by which the balancing of an enormous aggregate of payments involves only an infinitesimal movement of coin or currency, yet the corresponding process of balancing imports and exports by means of foreign bills of exchange is not so generally understood. This unacquaintance largely arises from the circumstance that the gathering together of such bills is in few hands, and the individual trader or manufacturer has seldom occasion or opportunity of seeing the process. Those whose business or profession makes them familiar with the subject, may require a special effort of mind to realise what appears to them a mere rudimentary knowledge is not shared by others, and such well-informed persons will probably find nothing of interest in this paper. None the less, it is a fact that manufacturers and traders do not, as a rule, recognise the principles which govern the foreign commerce of the country. It is true that various books on political economy deal with the subject, but generally in an abstract manner which does not bring the matter home to those who are engaged in particular branches of trade.

The "Theory of the Foreign Exchanges," by the Right Hon. G. J. Goschen, M.P., published in 1863, is still the standard work, although there is need of a new edition brought up to date. The present writer does not presume to touch on the higher branches of the subject as dealt with in the above treatise, or with the more subtle causes of fluctuation in values. It is here merely attempted to give such a summary description of foreign exchange as may assist the ordinary trader in understanding the methods and principles involved.

The historic study of the subject is interesting and fascinating. Barter of goods between foreign countries, even in remote ages, was facilitated by instruments of exchange, as the remittance of gold and silver was troublesome, and did not effect the purpose of the merchant. Among the commercial cases argued before the Athenian Courts were often some relating to the import and export of merchandise; and the eloquence of Demosthenes, as recorded in his private orations, upheld the right of his clients to letters of credit transferring debts in foreign cities. In still more

ancient times, the Chinese transferred indebtedness in distant parts of the empire by portable tablets, suitably impressed. But leaving on one side such ancient histories, the use of foreign bills or letters of credit in Europe was introduced in the 13th century; while, strange to say, inland bills only came into use in Great Britain, and became recognised by law, in the 17th century. In the reign of Edward I., credits on Genoa, Venice, Bruges, Antwerp, Hamburg, and elsewhere, could be purchased in London, with every certainty that they would be honoured on presentation; and a merchant visiting these cities could, if he had no goods of his own to exchange or sell, and without actual money in his possession, provide himself with the means of making purchases. A travelling merchant, so equipped, ran no risk of impoverishment from robbers, the letters of credit he carried being worthless, without some genuine endorsement or authentication. As an able writer has said of the Lombards of that time:—"They invented the letter of change, which immaterialised their wealth, made it portable, imperceptible, defying the confiscation of their persecutors." Or, as Lord Overstone once described bank notes, "they were the shadow of the gold." By gradual growth, the use of bills has vastly extended; they are protected by the laws of all civilised countries; every incident, however trifling, in the commerce of such bills has been strengthened; so that, by a natural evolution, they have attained the position of instruments of barter and exchange.

Let a foreign bill be followed in its track across Europe. A Russian merchant, in Odessa, has shipped wheat to a customer in London, and wants payment. Alone, or under the direction of his banker, he draws a bill on his customer in Mark-lane for the agreed value of his wheat, say £1,000. He draws the bill, say at three months' date; he draws it in favour of the banker (that is, to the banker or his order), and in duplicate, the copy becoming void when the original is paid. The bill, being drawn in Odessa, would be dated according to the old style, and would probably be in French; in English, it would read—

> £1,000. Odessa, 1/13 February, 1892.
> Three months after date pay this First of Exchange (second being unpaid) to the order of Messrs. Kopeckoff, One thousand pounds sterling, value in account.
> PAUL SITOPOLEVITCH.
> To Messrs. John Smith & Co.,
> 500, Mark-lane, London.

Sometimes bills are drawn in triplicate—first, second, and third. The drawing of more than one copy may probably have arisen, for safety and convenience, in days when transmission by post was uncertain. The duplicate, or copy, is now useful in the negotiation of the bill. The banker, whose business it is to buy and sell bills, and who has a personal knowledge of the corn exporter, buys the one in question at a certain rate of exchange, and either pays to the merchant the price in roubles, or makes him an advance till the bill is accepted. He pays for the bill less than the par value in roubles of pounds sterling, because three months' interest has to be allowed for; and he pays slightly less than he would sell at because, like a jobber on the Stock Exchange, he takes as his own profit "the turn of the market." The banker has bought the right to £1,000 in London three months after the bill was created.

Immediately he has bought the corn bill the Russian banker sends to his agents, Messrs. Blank and Co., in London, the original or "first of exchange," with instructions to present it for acceptance. The London corn merchant having been duly advised by the vendor in Odessa of the shipment, and of the drawing of the bill, accepts in ordinary course, and Messrs. Blank and Co. lock up in their safe the accepted bill to await further instructions. The bill, though accepted, is as yet incomplete and useless, for it is not endorsed; the banker in Odessa by this omission retaining his property in the bill. For he also wants to sell it when he can do so at a profit, and on 'Change every day, or in his Counting-house, he waits a purchaser.

A dealer in agricultural implements, who has ordered some thrashing-machines from Lincoln, wants to remit to England, and purchases from the banker as sufficient for his purpose, or as part of a larger sum, the £1,000 bill. The banker endorses to the order of the machine importer and hands to him the copy or "second of exchange," and so gets back his roubles—presumably at a profit. It will be seen that the buyer of the bill has not got a complete document, the bill, though endorsed, bearing no acceptance. But at the foot of the copy is an intimation where the original or "first" is lying in London, and the Lincoln engineer (or his banker for him), presenting the second of exchange as his authority, demands and receives the original with its acceptance. The two—the original and the copy—are pinned together, and so

form one complete document which, on maturity, is presented to the merchant in Mark-lane, or to the bank named in the acceptance, and is paid. It will be seen that although all the parties concerned obtain the money they desire, the Lincoln engineer in sterling, and the Odessa corn exporter in roubles, no money has been remitted either way, nor does either of the parties know of the other's share in the transaction. Although really a barter, the intervention of the bankers hides the nature of it from those immediately concerned. Each has demanded money for his goods, and has received it.

It may be noticed here, in passing, that the reciprocal payments are not made in the same way. While the Odessa merchant generally finds it better to draw on London than to ask for money to be remitted to him, the Lincoln manufacturer prefers, rather than draw a bill on Odessa, that his customer shall remit to London. The foreign importer of British goods also finds this method best, for he can always buy bills payable in London. Obviously, however, this is not a universal rule. When credit is allowed by the English exporter, and especially in the smaller branches of trade, an infinite number of bills are drawn from England upon foreigners to whom goods have been sold. In the English hardware districts, for instance, bills for sums as small as £20 are drawn at dates even up to six months, and such bills, while they go to swell a total which has due weight in the exchanges, are not passed so frequently from hand to hand as are the larger bills of well-known firms.

The example of the Odessa corn bill is, however, a simple transaction comparatively direct, and does not always occur. Indeed, the Lincoln engineer might say of it, "I only wish it were true; my neighbours and I are getting very few orders for machinery from Russia, and yet I see Russian wheat in undiminished quantities coming in." Perhaps it is for Sheffield cutlery, or Nottingham lace, or Bradford merinos, for which the corn bill has been used, and if so the effect on British commerce is the same. But possibly the Russian tariff may be so vindictive against Great Britain, and so wide in its grip, that not nearly enough of these goods are imported to pay for all the wheat that comes, especially when the Russian hemp and tallow have also to be paid for.

If such an uneven case were to occur, and it often does occur between countries, and unless some easy remedy or alternative presented itself, the trade in wheat would be impeded. For the price in roubles at which bills on London could be sold would fall; an entire absence of buyers may even be imagined, and the wheat exporter would have to ask for gold to be remitted to him, the whole cost of which operation—freight, insurance, conveyance to a Russian mint, and commission on its sale—falling on the wheat exporter. For the English buyer would oniy pay the current price of wheat as determined by the supply from all other sources. Such extreme and imaginary cases seldom happen.

When the demand for bills just equals the supply, the exchange stands at par, the money of one country having a value compared with the money of another exactly according to its gold equivalent. (Fluctuations because the money of a country is in silver, or depreciated paper currency, are domestic questions which do not pertain to the present discussion.) As in the case of general merchandise, so with bills of exchange, slight oscillations are always occurring in the supply and demand which cause the price of bills—namely, the rate of exchange—to vary. Dealers who anticipate a change in the rate will buy or sell bills speculatively, as would a dealer in any other commodities. But the par value tends to right itself automatically. For—to continue the Odessa example—if owing to a slackness in the demand for British goods there be more sterling bills on London than there are buyers for, the price falls to a discount; the export of merchandise is discouraged, and the purchase of British goods is encouraged, as Russian merchants can buy sterling bills cheaply and so neutralise some of the tariff impediment. And the same over-supply in Odessa of bills on London which causes a discount there produces in London a premium on bills payable in Odessa, so that an English merchant is encouraged to ship goods there because he can sell at a premium the bills he draws against each cargo.

The greater the inequality in the exchange of goods, the greater becomes the discount and premium respectively, the bills being the mere instruments which enforce the inexorable rule in any country, that if imports are prevented or impeded exports are immediately restricted, the country that imposes the barrier being the one to pay the penalty. But the Odessa banker, notwithstanding the excess of Russian exports over imports, is still willing to buy the bill for a good price if he has other customers for it. He may sell it on

"Change" to a banking agent, who wishes to send it to St. Petersburg to make up a remittance to London for interest on Government bonds, or for paying the rent, interest or dividends on British investments in Russia. Or possibly he may obtain a better price by selling the bill for commercial purposes. An Odessa wine merchant, who has bought claret and brandy from France, wishes to remit money in payment, so he buys the corn bill, endorses it to the wine-grower, and sends it to Bordeaux, for he has to pay in francs, and he sees by the daily-published lists of exchange-rates that the value in that city, measured in francs, of English sterling bills, is good. The wine-grower, on receiving the bill, endorses it over to his banker, who credits him with its value and resells it. The exchange price may not, however, be due to a great demand for remittances to England, for Bordeaux may be sending more wine than she is taking English goods in exchange, but there is a brisk import of Saxony woollens, and the bill is again endorsed, and is sent off by a dry-goods merchant to Chemnitz to pay for hose. By this time thirty days of the bill's course has run, and its value has increased as the allowance for interest becomes less. On its arrival in Saxony it is purchased by a wholesale dealer in colonial produce, who has to remit to Amsterdam payment for a large consignment of Java coffee which he has bought. Norhing is more acceptable in payment than a sterling bill on London. Finding that all the space on the back of the bill is already covered by endorsements he gums on a further six inches of paper (*allongement*) and writes his name. In Amsterdam the bill is bought by a banker who keeps it a few weeks, and then sells it to a Dutch railway company which has purchased some locomotives in Manchester, and has, by agreement with the manufacturer there, to provide money at a London bank to pay cash against bill of lading. So that at last the cargo of wheat is settled so far as the two countries are concerned by a Dutch transaction, and the balance of indebtedness is adjusted. It will be seen that the bill, though it has taken a tortuous route, has, to use a scientific illustration, followed "the line of least resistance," and going at each stage in its journey to the place where London bills are in demand, automatically found its destination with those who are willing to buy British manufactures. In short, the Russian wheat-importer, being prevented by his country's fiscal system from selling his bill directly to an importer of British goods, has, through the machinery of foreign exchange, found a substitute.

The foregoing is by no means an exceptional case. On the contrary, the course of such bills and their effect are frequently much more intricate. But before referring to other incidents, the reasons which give to bills on London their pre-eminence as instruments of exchange may be touched upon. At the very basis of British credit is the traditional belief abroad in the integrity of British traders who, as a class, are known to fulfil the spirit as well as the letter of their engagements. The payment of the bills is in pounds sterling, that is to say, in gold of a specified weight and fineness. There is no risk of payment having to be accepted in silver or currency of fluctuating value. The buyer of a bill, and he who takes it in payment, knows exactly what he is to get. The payment at the date due is certain. It is true that the bill represents a debt, but no one has to be sued or dunned; it is to be paid without question on presentation. When the bills are those drawn directly by bankers on any one of the leading financial houses in London, experience has shown that such bills will be honoured, the per-centages of failure in this respect being so minute as to be hardly worth consideration But, in the case of bills drawn on mercantile firms who may not be known to those who buy the bills, it is necessary to remove even the smallest feeling of uncertainty. In the case of the corn bill, the Odessa banker knows that actual value is represented; for he is acquainted with the customer who draws the bill, and is aware of all the circumstances. But the subsequent buyers of the bill have no such knowledge, and might hesitate to rely absolutely on the means and good faith of the acceptor. No room must be left for doubt, for, at each transfer, full value in money or merchandise is irrecoverably given, and there is no margin for risk. It is not always enough to know that, in case of the bill being refused acceptance, or of being dishonoured by the acceptor, the endorsers are liable. There is probably an ultimate security in this, but delay and expense would be involved, if the bill had to retrace its journey, each endorser paying to the one who took the bill from him, and recovering from the previous endorser.

There must be an immediate remedy in London that will maintain the prompt cash value of the instrument. Therefore, the original banker, in whose favour the bill is

drawn, and who intends to use it as a negotiable instrument, clenches the matter, by adding a guarantee beyond that of the actual parties to the bill. This is one of his functions as banker, and the risk is incident to his business. This guarantee is effected as follows. Almost all foreign bankers keep a moderate amount of money, or, what is as good, credit in London, which, though inadequate to pay all the bills drawn in their favour and bearing their endorsement, is quite sufficient to protect them all by paying in the very rare and occasional instance of the acceptor failing. At the bottom of the second of exchange, which is the negociable copy of the bill, is inscribed, "The first and in case of need with Messrs. Blank & Co." The first part of this inscription is, as already mentioned, a mere direction as to where the accepted "first of exchange" is to be obtained; the second part informs all concerned that Messrs. Blank will, for the honour of the first endorser (the Odessa banker), pay the bill if the acceptor fail to do so. So immediate is this payment, that the numerous endorsers of the bill need never know of the temporary default, and they have no concern in the subsequent steps that may be taken by Messrs. Blank to enforce payment from the acceptor, and, he failing, from the original endorser, the Odessa banker. Not only, however, has the Odessa banker given the "in case of need," but some of the other bankers, through whose hands the bill has passed, have added theirs also, so that when the endorsed copy, or "second of exchange," reaches London, it may have two or three such inscriptions, each giving a separate name in London.

It will be seen how important this guarantee is to all concerned. To the traders, because the value of the document for which they have exchanged merchandise is ensured; to the bankers, because their credit is maintained. If delay or doubt once arose, the negociability of future bills bearing their impress would be endangered.

Besides the bills that are sent to London by the buyers and sellers of merchandise, a large proportion reach their destination in parcels from the foreign bankers who have purchased them, and who thus maintain in England sufficient funds to meet the drafts which they make from time to time. Indeed, this mode of procedure is increasing, and the proportion of commercial bills remitted directly by traders tends to decrease. For those in foreign countries who have to make purchases in England, often find it more convenient to open a credit through a banker in their own country than themselves to purchase bills to remit direct to the manufacturer or merchant with whom they are dealing. By this course the banker, through his London agent, acts as the buyer's intermediary, and protects his interest by paying over the money or accepting a bill in London only against a bill of lading. But all the same, the money paid in London is the product of bills drawn in a foreign country against merchandise; bills which have a negociable value in that foreign country only because British goods are to be imported, although not necessarily into the country where the bill is drawn.

There are also merchants who may be called merchant-bankers, whose transactions are so large and widely spread that they may be able in their own house and its numerous branches to do a reciprocal trade, that shall effect the balance above described. A small merchant or dealer often finds it expedient to sell his produce or his merchandise to such a firm, instead of himself seeking a customer in a foreign country. If the business of these large houses could be disclosed, it alone would illustrate the process which it is attempted here to describe.

In making remittances, especially of large amounts, for precise sums, it is not always practicable to obtain a parcel of commercial drafts which give the desired total. But, as already stated, most foreign bankers, even those who do not make large drafts, have funds in London against which they can draw cheques of moderate amounts to make up differences. Bills of small amounts are also supplied by those which tourists draw on London against the letters of credit or circular notes which they carry with them. Cheques drawn by tourists are, as a rule, readily cashed if they are on an English and (by preference) on a London bank. Or the dividend warrants which a British resident abroad has had sent to him from home may, after he has endorsed them, be cashed by a local money-changer who, treating them as London cash instruments, will re-sell them to importers who have to make payments in England or elsewhere. Other small bills are those of retail shopkeepers and agents, who have sold goods of trifling amounts to English buyers. But a need for small currency, which shall be international in its character, has often been felt, that is to say, currency which will be received by bankers, money-changers, and others in all

important business centres. Post-office orders are not always convenient, and those for foreign countries involve considerable commissions. In Europe the want of small currency has occasionally led to the use of Cook's hotel coupons. Although these range in value from small sums of a few shillings and upwards, they are in effect bills of exchange, as they are payable in London on demand, and in sterling. Although generally cashed for the hotel keepers by Cook's branch agencies abroad, money-changers will also buy them from the hotel keepers, and not only include them with bills of larger amount to make up an exact sum for remittance to England, but there is no reason why they should not send them to any part of Europe. But whether sent to England direct by Cook's own agents, or by an indirect course, they form part of the aggregate flow of value in both directions. The first holder, the British tourist who originally bought them in London, has purchased with them food or lodging on the Continent, but, by the inexorable and automatic law of foreign exchange, these purchases have been met by the foreigner buying British goods.

There is a reciprocal current of credit notes expended by foreign tourists in England. The money spent by American travellers in Europe is greatly in excess of the expenditure by European travellers in the United States, and this not only in mere travelling expenses but in the purchase of goods, advantage being taken of the much lower prices that prevail. Clothing, jewellery, trinkets, and all kinds of personal wares, are bought to such a large amount as to tell considerably on the exchanges. But while the credits on London, purchased in New York by intending travellers, are drawn against the produce shipped to Europe which appears in the Board of Trade returns, the credit notes do not appear, nor do the goods purchased and taken home as personal baggage. The examples given here of the kinds of bills payable in London are, from a banker's point of view, few and incomplete. Treasury bills, issued by the British Government, and due six or twelve months after issue, are largely held on the Continent, and are applied to the payments for British goods. So also are bills drawn on London at military or naval stations, or by captains of British war-ships in foreign ports. Such bills are freely bought by merchants and bankers, and reach London after passing through many hands as already described. But for the limited purpose of this paper the examples given may suffice. Besides the certainty in regard to the time and manner of payment of sterling bills, the vastness of the trade concentrated in London has made that city an international clearing-house, and, as already noticed, it is found convenient by foreign as well as British traders to settle all transactions there. And this applies, as will have been seen, to transactions entirely foreign, sterling bills being used as international instruments for purchases and sales between foreign countries, having nothing of the British element in them. This is no small advantage to Great Britain, because, as it is generally easier to buy bills or credits on London than on any other city, a preference will be given to British manufacturers when purchases are thus facilitated; and as all money dealers abroad are obliged to keep in London money or its equivalent, there are large balances available on moderate terms to English borrowers, and the rate of interest is low.

It is endeavoured here to show that what is generally spoken of as the balance of trade is regulated automatically, that the commerce in foreign bills serves as a gauge or measure to record it, and that neither Parliament nor Congress can in the long run divert the natural flow of trade, although they can, by mischievous interference, impede or restrain it. To diminish imports while increasing exports is the ideal of many traders, who do not recognise that the placing of barriers in the way of values coming in, is in effect the checking of customers who are coming to buy, and whose products form the purchase money.

The Board of Trade returns of imports and exports are often studied to see how the balance of trade stands between Great Britain and other countries, and one reason for the misunderstandings that arise is, that the balance is hardly ever entirely a direct one, and that a third country, or the trade of many countries, has to be brought into the account in order to complete a proper statement. Or, in other words, the total exports and the total imports must be set against each other to ascertain the real condition of affairs, and to judge of the wisdom or otherwise of a particular policy. Let it be assumed that a particular country is sending to Great Britain merchandise to double the value of what she buys as shown by the official returns. First, it must be remembered that the amounts shown in the returns need qualification. The value of British exports is declared as the value at the port of departure, and the freight which is

received by the British ships that carry the goods has to be paid by the foreigner, so adding considerably to the total sum received by this country, a sum in excess, therefore, of the mere free-on-board value. It is further to be remembered that exports include capital investments or loans, no immediate balancing of which is expected, but for which profit or interest is looked for in the future.

On the other hand, the value of imports as entered at the British Custom-house is the value delivered at the port of arrival, and the freight earned by British carriers has to be deducted before the net sum paid to the foreigner can be ascertained.

Secondly, the imports into this country are swollen by the tribute, *i.e.*, the interest or profit just referred to, that has to be sent here in the shape of dividends on loans and other British investments abroad.

Thirdly, and this is the point it is desired to emphasise here, the balance of trade may appear to be largely against Great Britain in regard to a particular country even after making allowances as above, and yet the balance be really in her favour.

If an exporting country, by its prohibitive tariffs or otherwise, refuses to buy from Great Britain as much as it sells, it must find a substitute in someone else who will buy, so as to redress the balance. If this is found to be the case, then the apparent adverse balance will be explained and neutralised. To take a concrete case; if after making all the allowances for freights and interest on investments just referred to, the purchases by Great Britain from the United States were to exceed the sales to that country by £5,000,000 per annum, there would be a full compensation for the apparent loss if the United States, in order to make these excessive sales, were obliged to find some other country or countries more complacent in regard to purchasing from Great Britain, who took British goods in preference to those manufactured in America. It is endeavoured here to show that such compensation does really take place.

London is the great meeting place and exchange for values between East and West, a large proportion of the trade between the United States and Asia involving a flow of bills through London. This affords another example of the indirect course of foreign exchange. Large quantities of Chinese tea are imported into America, as also spices and other products from British India. The exports of the United States to these countries are not sufficient to balance the imports from them: the petroleum, silver, raw products, certain kinds of cotton cloths, a few other manufactured goods, and small wares that America is able to send there not equalling the drafts that have to be met. For the principal manufacturers of the United States have so large a market at home, that they prefer to maintain high prices there which are unattainable in neutral markets, and are content to leave the supplying of manufactured goods to the East in European hands, mainly in those of Great Britain. In 1889 (the latest year for which published returns are available for reference) the United States imported from the East Indies, Australia, China, and Japan produce and merchandise to the value of £12,250,000, while the total export to these countries only amounted to £5,500,000. And as it may be assumed that the United States have little revenue due to them from investments in these countries, the difference has to met in some way. Therefore, in order to pay for tea and Indian goods, the American importer instructs the exporter in these Eastern cities from whom he has bought, to draw for payment on London houses with whom he has arranged to meet the drafts. He provides the necessary funds in London by exporting American produce to England, or by buying the produce drafts on London originated by others. The proceeds of these Eastern bills drawn on and payable in London are used either by the native merchant in India or China or by some other merchant in these countries, who has purchased them for the purpose, to pay for British manufactures. The original drawer generally desires to sell them, for like the Odessa corn merchant, he wants payment at home. There is a limited number of financial firms who have houses in Chicago, New York, and other American cities, as well as in London and Paris. These firms have corresponding houses in the East, or in London trading with the East, and are able to grant credit in either direction to American, European, or Eastern merchants. It is these banking firms who collect, exchange, and distribute the drafts based on the merchandise, and for this reason the traders who avail themselves of their services are often not aware of the machinery which deals with the international exchange transactions.

In regard to South America also exports thither from the United States of flour, oil, ice, timber, and other products do not always suffice to pay for the coffee, hides, sugar,

and diamonds that she buys. Thus, in 1889, the United States imported to the value of £12,000,000 sterling, and exported thither only £2,000,000, and the United States has therefore to adjust to her indebtedness by means of bills or credits based on European (largely British) exports of railway material, iron, steel, or soft goods. These bills or credits are, as in the case of the Chinese and Indian trade mentioned above, paid for by shipments of American wheat, pork, cheese, copper, and other native products to Great Britain.

It will be seen, therefore, that the United States, when their imports of British goods do not suffice to repay them for all the produce they have shipped to Great Britain, are obliged by the automatic action of foreign exchange to find substitutes to purchase more British goods; and Huddersfield woollens, Bradford merinos, Manchester calicoes, Middlesborough steel, and Leeds machinery, go to pay for a corresponding balance of coffee, tea, and spices consumed in the United States but unpaid for by American exports to these countries.

But though by barter of goods trade must, in the long run, be made to balance through the machinery of foreign exchange, the commerce in bills does not always suffice for sudden or spasmodic alterations. In these cases gold and silver and saleable securities come into use to reduce the differences. Thus, in the spring of 1891, there were, in view of an impending increase of Customs' tariffs in the United States, larger shipments thither of merchandise than could be paid for by American produce, and much gold had to be shipped to Europe. Not only the shipment of gold, but the sale to British purchasers of railway and other bonds was encouraged, for every instrument that had a money value in London was in demand. No record of such sales appear in the Board of Trade returns. In the following autumn there was a lull in the shipments from Europe, because the spring surplus was not yet consumed, the tariff alterations had diminished or stopped the flow of certain goods, and the compensating growth of other kinds had not fully taken effect. Besides this, the extraordinary shipments of wheat to Europe caused a flow of gold back again, and the re-sale of American securities by British holders was encouraged. Such movements of the precious metals are only temporary, and, like water, finding its level slowly, because through tortuous channels, so does foreign trade at last balance by the flow of merchandise. Boxes of British sovereigns or American eagles pass backwards and forwards, as make-weight, and frequently remain unopened in bank cellars till they are needed to make another journey back again. The stock in State and municipal debts is transferable; the creditors, to whom interest must be paid, may be either national or foreign; and such creditors may become more or less national or foreign under the stress of the balance of trade. The purchase and sale of United States bonds and shares, and corresponding dealings with European securities, are taking place every day, the demand and supply and the prices being considerably affected by the course of exchange. There is, necessarily, a constant ebb and flow; but as, in the long run, the aggregate holdings of British investors do not diminish, the real balance of trade is not against her. And, in the same way, notwithstanding the movements of bullion, the stock in Great Britain does not year by year become less.

Although, as a nation, the United States has elected to forego a foreign export of manufactured goods, preferring to pay high wages at home to balance the high cost of living, rather than manufacture under normal conditions at a price which will command a foreign trade, there are manufacturers there—growing in number—who are not content with this exclusion from the world's commerce, and who are attempting to influence legislation in their favour. The making of treaties has been authorised by which foreign countries shall be bound to give a preference to high-priced American goods over those offered more cheaply from Europe, the inducement being that produce from these countries shall receive from the United States a corresponding preference by discriminating tariffs imposed on produce from other lands. This policy is most likely to succeed with Canada and the West Indies, whose contiguity to the United States renders the latter desirable as a market for certain kinds of produce. It remains to be seen whether the advantages offered by the United States are worth the price demanded, and how far this attempt to divert the natural flow of trade will succeed, and if it does succeed, its effect on foreign exchange. Commodities ultimately find their destination according the wants of the consumer, and low-grade coffees from Brazil will not shut out the better kinds from Ceylon, even by being cheapened; nor is it likely that the railway companies of South America will consent to pay high prices for American loco-

motives, or Brazilian workmen to pay dearly for American cutlery, because the coffee of their countrymen finds a preferential market. It is more probable that in regard to these countries the increased imports from the United States will be in the form of petroleum, canned meats, and similar produce.

In England also, some manufacturers propose to influence legislation in the direction of "Fair Trade" which shall divert the natural flow of merchandise, and give a preference to those countries which will buy the Britsh goods the fair traders are personally interested in; the inducement offered being a preferential importation of agricultural produce from these countries by taxing the goods of all other countries. The extra cost thus incurred would have to be borne by the British people in general, while the benefits would remain first with the manufacturer interested, and, secondly, with those in this country who can furnish agricultural produce, and whose prices would be immediately raised when the competitive imports were restricted. This, though it might improve rents, would do so at the expense of the consumer.

"Imperial Federation" is another plan of obtaining the same result. The growing cry for federation is natural and patriotic, but there is so universal an agreement on the desirability and advantages of a closer bond between Great Britain and her colonies for mutual defence, that the zeal of those who advocate it would be better employed in formulating a feasible plan, for up till now, unfortunately, the loudest support has been given by those who take advantage of this popular cry to promulgate their "fair trade" theories under the guise of a British Zollverein. By this they mean a system of reciprocal treaties with the Colonies on the lines just indicated, and which, it is hoped, will produce like results. It has, however, been sufficiently shown that the Colonies will not consent to any such plan, and this for two main reasons. Firstly, because the duties Great Britain would be willing to impose on countries outside the Federation—probably 5 or 10 per cent.—would be quite insufficient as an inducement to the Colonies. Secondly, because those in the Colonies who influence legislation—the working classes in the towns—would not see that any benefit would accrue to them by such a system. Although in Australia the protection of local manufactures is favoured, and the cost of imported goods enhanced, the working-men voters would not consent to "discriminating" duties which would give a preference to British manufactures over those from America and Germany. For even if it can be imagined that Great Britain would tax the copper, and wool, and mutton from countries outside the Federation, for the supposed advantage of the colonists, it would be the colonial landowners, the squatters, and the capitalists who have such mining and agricultural products to export that would gain all the benefit. As a matter of academical discussion, however, it might be interesting to consider how such treaties, if put in practice, would affect the exchanges.

It will be seen how difficult it is to touch at all upon the subject of bills of exchange, without referring to the goods they represent. The desire to shut out the foreigner from supplying the home customer is common to all manufacturers and shopkeepers everywhere. The sight of foreign wares on shop counters is palpable, and touches keenly the home producer with whom they compete; while the effect on an export trade of restricting imports is too remote, and does not present itself so vividly to the imagination. This is not to be wondered at in those who are occupied in making or selling British goods for use at home, and who measure the prosperity of the country by their profits from such business. But those who manufacture or sell for export, should realise that there must be a return current, if trade is to be maintained and encouraged.

The principles here put forward may, to those who are familiar with them, appear truisms, which it is a waste of time to enunciate. This country, it may be said, is too firmly established in free trade to need any arguments on the subject. The author ventures to assert that this view of the subject is erroneous. Directly there is a depression of trade, the discontent —which has only been dormant during prosperous times — becomes widespread and aggressive. In the manufacturing districts especially, the majority—master and workman alike—look only at trade from their individual standpoint, instead of from a national point of view. Such persons would probably support the abstract desirability of restriction, although they might not venture to formulate a plan. The present example of France should be a warning, for in that country this view is being logically applied. It is to maintain existing investments that a burden is being inflicted on France, which, in its crushing effect, will

be almost as bad as a war or a pestilence. In this country the real impediment to retrogressive legislation does not lie in any universal opinion that restriction is bad, but because first it is obviously undesirable to make food and raw products dearer; secondly, that if they were left still free of duty the balance of imports available for taxation is hardly worth consideration; and thirdly, that if manufactured goods were taxed at the Custom-house there would be a great disagreement in regard to which were to be taxed, and how, for the finished product of one industry is the raw material of another. So that, if even there were an agreement as to the principle, there would be fortunately no chance of agreement in the application of it. It is true that if the tariff be exclusively or specially directed against a few particular commodities, they may be restricted or even entirely shut out. But such a course only diverts the current of purchase to some other articles, for the country as a whole must somehow receive payment for its exports.

The old fallacy that an excess of imports over exports is a disadvantage to any country as making "the balance of trade" against it, may be modified or removed if it be noticed that an excess of exports is only to be seen in poor countries. Great Britain in 1890 imported merchandise to the value of £420,000,000 and exported £382,000,000. France, also a rich country, imported in 1889, £172,000,000 and exported £148,000,000. The United States, a rich country, but with great indebtedness to Europe, had her imports and exports nearly equal £152,000,000 to £155,000,000. Russia, which is a poor country, importing only £37,000,000, had to export £68,000,000 to adjust her indebtedness abroad. But occasionally there is the apparent anomaly of a poor country being able to import largely. Thus the Argentine Republic, in the six years ending 1889, imported £138,000,000 and exported only £105,000,000, but this arose from the very large investments of European capital, mainly on account of loans and public works. If left to her own resources the excess would have been the other way, as is now the case, when investments have ceased. In the years 1871-2, after the Franco-German war, there was a similar excessive flow of British capital to Central and South America with a view—not altogether realised—of obtaining interest or revenue in return. Not only, therefore, is it necessary to regard the trade of many countries in order to arrive at the condition of any one, but the trade of many years must be averaged if trustworthy results are to be obtained.

The peculiar effect of heavy tariffs is shown in the woollen trade between the United States and Great Britain. Every wool-producing country can only, because of climate and breed of sheep, produce certain kinds of wool. In Scotland, districts only thirty miles apart are dissimilar, and the wool in Shetland is unlike that in Yorkshire. The wool in the United States is again different, and for certain goods is more suitable than wool obtainable anywhere else. But Australia, New Zealand, and Buenos Ayres produce other special kinds; while the merino of Australia gives another variety. These countries grow more wool than all others put together. In Great Britain enormous quantities of each kind are available; the manufacturer is free to choose from all the varieties, each for a particular cloth, or can combine them in any proportion. In the United States, on the other hand, a manufacturer finds that the price of native wool is enhanced by the protective tariff on competing kinds, and if he desires variety, a study of the tariff book restrains him from buying the foreign wool. Being thus impeded, the practice and skill for making good cloth are not acquired; and notwithstanding an import duty, ranging from 50 to 150 per cent., Yorkshire woollens continue to be profitably exported to the United States, while the manufacture there is in a depressed condition. It is true that when the tariff has been directed against the rough cloth, for which American wool is suitable, it has succeeded in diminishing the importation of foreign cloths of a similar kind; and the British manufacturers who formerly supplied them have been led to direct their attention to medium and finer grades, where the use of highly skilled labour is repaid. The shutting out of the cheaper kinds of Yorkshire woollens has, by removing competition in America, enhanced the price of workmen's clothing there, but in regard to the finer kinds which must come from Europe, higher prices have only moved a little upward the stratum of society which can afford to be well dressed; more medium woollens have superseded the finer kinds; and the purchase of clothes in England by American travellers is encouraged, as already referred to. The clothing taken in the baggage of the travellers makes the real total of woollens exported greater than the apparent total shown in the Board of Trade returns. The export of certain kinds of woollens

from the United States to Europe, which would certainly take place if there were free exchange, is prevented, to the loss of both countries.

This system of disturbing the natural flow of trade and making artificial prices loads even the natural products of the country where such a system prevails. Meat and grain and vegetables, which are cheaply produced in the United States and sold at low prices in Europe, are dear to the American retail purchaser, because directly these products leave the cars or vessels which bring them to the large cities, the expenses of rent and salesmen's wages so increase the price that good meat and bread are as dear in New York as in London, and Florida oranges are dearer.

The transference of manufactures from one country to another under the stress of hostile tariffs, has sometimes curious results, not immediately apparent. The United States, in their desire to be a self-contained nation dependent only on themselves, welcome any foreigner who will bring skill and capital to employ local material and labour. Undoubtedly the tariff, if made stringent enough, tends towards this result, although sometimes it is difficult to transplant effectually industries which have had the advantage of traditional and hereditary skill, and the benefit of numerous preparatory and subsidiary trades which have grown up around them. But there is also a return current. The genius of inventors and manufacturers in the United States cannot always be satisfied with the home market, and some among these classes desire to compete with European manufacturers in the neutral markets of the world. Great Britain and her dependencies alone offer a wide field. Not only in Liverpool and London, but in Calcutta, Hong Kong, Cape Town, and every British colony would American goods find a market. American ships and cargoes would be received as freely at all these ports as British vessels and cargoes, neither harbour dues nor Custom duties being heavier on the one flag than on the other. If foreign exchange were allowed free scope, there would be a mutual trade, to the advantage of the world; but the tariff in the United States holds back her export vessels as surely as if they were tethered to the shore by unbreakable steel. There are only three methods by which American manufacturers can sell their goods abroad, but, as yet, only two of these methods are adopted. One is, by selling them at less than a usual profit or without profit. American watches and sewing-machines can be bought in England at lower prices than in America, because some of the cost is imposed on the goods sold at home, where the price is protected. The same system has been applied on the Continent. Germany sells steel rails to Italy and Spain at less prices than to the German railways, the latter being charged an extra rate per ton to provide a profit on what has been exported.

The second method of finding a foreign market is to transfer the manufacture thither; so that, while the British manufacturers of silk plush, sewing-cotton, and printed books, set up workshops in America to supply high-priced goods, the American manufacturers of steam-boilers, sewing-machines, mining machinery, and steel screws cross the Atlantic, and employ British material and labour in London, Glasgow, and Leeds, for goods destined for the whole world outside the United States, and send to these British cities for execution the foreign orders they receive at home; orders which, under normal or free conditions, would naturally be executed in America. Bounties on export form a third resource. The drawback granted to the French sugar refiners is in effect a bounty, with the result that French sugar can be bought in London or Leeds for half the price charged for it in Paris.

It is in vain to struggle against the inevitable. In Russia, thousands of tons of wheat have rotted at remote railway stations for want of rolling stock. Prohibitive tariffs have prevented the importation of wagons, and the home manufacturers cannot supply the need. In Australia may be seen, on a small scale, the same futile attempt. A reluctance to buy from Europe what the working-class voters think they can make at home, induces them—not only in Victoria, but in New South Wales—to promote the establishment of factories on an impossible basis. The railway traffic of these Colonies has been hindered, while attempts have been made to manufacture locomotives and railway material in the Colonies. These attempts have failed, just as have those for manufacturing iron, steel, and woollen goods under abnormal conditions. And if success could even be imagined, any reduction of such imports must cause a proportionate falling off in their exports of wool, copper, and wheat, the prices of all these commodities suffering a corresponding reduction in price by the competition of producers under a diminished demand.

Those who are discontented with the balance

of trade have constantly before them an awful chimera, an imaginary future when protective tariffs abroad will have become so universal and prohibitory as to shut British goods out from all foreign markets. Then, it is feared, will come a time when Great Britain will have to pay in gold for all she buys abroad; and, indeed, the continued shipments of bullion from England are looked upon with suspicion. London is the centre of the bullion trade, and much of the gold and silver imported from mining countries has been brought here to be re-exported. In 1890, Great Britain imported £34,000,000, part of which was sent her as interest on investments, and the remainder as payment for British merchandise. About three-fourths of the £34,000,000 was re-exported, the difference serving to maintain the coinage, and for use in manufactures. And as the amount of gold in this country does not tend to diminish, those who look with anxiety on what they deem an excess of imported merchandise may be reassured. The sufficiency or otherwise of the reserve stock of gold coin in this country which exercises the public mind at present, does not pertain to the present discussion. These gloomy predictions are based on the fallacy that gold and silver are in themselves real wealth, instead of merely being the instruments of expression for property of a reproductive nature. When Spain and Portugal discouraged manufactures, and endeavoured to live upon the huge importations of gold and silver from their colonial possessions, their fall had commenced. The very countries which most impose restrictions on British goods—France, Spain, and the United States—derive a considerable portion of their wealth from their exportations to Great Britain, and take all their payment in manufactured goods; and if more effectual restrictions were imposed, bills on London drawn in these countries against exports would only be saleable at a discount; and unless some substitute could be found, as already described, the export trade would be so impeded, and prices so fall, as to compel a reactionary policy. The evil works its own cure. France and Spain must send somewhere abroad their wine and silk, America her agricultural produce, and, as there is not enough gold in all the world to pay for them, hey must accept payment in kind. The circumstance that such interchange or barter is disguised by the methods of foreign exchange does not alter the real fact.

Great Britain will decay, or her population decrease, when, through exhaustion of her minerals or decadence of her people, she can no longer manufacture, and not before; for so long as she is able and ready to buy, there will always be willing sellers, who must perforce accept the buyers' terms.

DISCUSSION.

The CHAIRMAN said it might appear, at first sight, as if the platform of the Society of Arts were not so suitable a place for a paper on this subject as some others, such as the Gresham College or the Institute of Bankers, at which a course of lectures on foreign exchanges had recently been given; but it must be remembered that their full title was the Society for the Encouragement of Arts, Manufactures, and Commerce; and it was found that, in the past, those nations which were pre-eminent in art were also successful in commerce; whilst commerce depended on manufactures, and they, in their turn, were largely dependent, not only on the useful, but also on the elegant arts. The consideration of the subject, with which these three mutually interdependent factors were so closely connected, was therefore by no means out of place. Looking forward to the World's Columbian Exposition at Chicago, to be opened in about a year's time, which had already begun to cast its shadow before, he took it that its great object was not merely to produce the greatest show on earth, but to develop the interchange of commodities, and a desire for the acquisition of the products of various nations. That Society was peculiarly charged with the representation of British interests at the Exhibition; and it would be the duty and pleasure of the Council, acting as a Royal Commission, to see that Britain obtained its full share of commerce likely to be developed by means of that Exhibition. It was always perilous to venture on a definition, but he should be inclined to say that foreign exchange meant the art of transferring, not gold, but the command of gold, from one country to another. Gold itself entered but in a very small degree into the ultimate settlement of transactions, and even the extent to which the settlement was performed by gold was extremely obscure and difficult to state precisely. With regard to wholesale transactions in the import and export of precious metals, the official returns were very misleading, and a reference to them would not lead to accurate results. Even in the case of France and England, the official figures in each country were by no means in agreement. With regard to retail transactions, the export of gold in the pockets of tourists, was very obscure. He had lately made some inquiries on this subject, and had received information from the United States Government, and had also made inquires on this side as to the probable amount exported from England in the hands of emigrants and re imported into England by the upper class of American tourists, and he

found that in the case of the largest credit issuing-house, not more than 10,000 sovereigns were required in the course of the tourist season. With regard to the amount taken away by emigrants, he had not been able to obtain any accurate information, or even to form any satisfactory estimate. The vast majority of operations between various nations was conducted by bills of exchange, which were held by some to have been invented by the Jews, who came to this country shortly after the Norman conquest, and who, when they were expelled, had recourse to this device for securing the transfer of their capital. They, undoubtedly, drew bills in respect of the wool shipped from England in payment of Peter's pence, and also legitimate commercial bills of exchange against similar exports. In those days a bill of exchange was a very solemn document. One of the earliest known examples was dated 28th April, 1404, from Bruges; it began "In the name of God, amen," and required the person to whom it was addressed to deliver to so-and-so, so many Barcelona scudi, the equivalent of which the drawer acknowledged to have received, and ended with a prayer that God would watch over the drawee. The minute details of the course of exchange formed an apparently intricate and, to most people, rather forbidding subject. If English coinage was all in sovereigns, and that of all other nations in pence, it would be easy to see whether there was a premium or discount on the exchange, if in the one case 245 and in the other 235 pence were given for the sovereign; but actual transactions were much more complex. In the case of France, sovereigns were dealt with in terms of francs; in Russia we did not convert the sovereign into the coinage of the country, but, as in India, calculated the number of pence given for the silver coin of the country. In Spain the practice was even more absolete. The paper dealt rather with the general course of transactions, of which a very good synopsis had been given. Mr. Matheson had shown himself to be not without some bias on the question of bimetallism and monometallism, but as having strong views on the subject of protection. fair trade, and free trade. It would take too long to go into those questions, but on the matter of the foreign exchanges there was room for a good deal of discussion.

Mr. C. M. KENNEDY, C.B., said the account given in the paper of the complex nature of mercantile transactions and the balance of imports and exports, and the real character of Custom-house valuations, seemed to him not only accurate, but very well put. With regard to the tariff question, what the United States had done had been to take off the duties from sugar and some other commodities, and then to say that they would be re-imposed, unless the countries which sent those goods to the American market made what the United States Legislature termed reciprocal arrangements, the object being to obtain preferential terms for American manufactures. That policy had succeeded in the case of Brazil, where a Treaty to this effect is now in force; in the case of the Spanish West Indies he was not yet certain whether a similar policy would prevail in the case of the British West Indies. A reciprocity arrangement had been concluded on behalf of the Colonies, but goods from the United Kingdom remained on precisely the same footing as United States goods. He thought Mr. Matheson was in error in thinking that Canada was likely to come into an arrangement o this kind with the United States, for he knew of no indication of it at present. It could hardly be said that the British colonies would not consent to what might be termed a British Zollverein; no definite plan of that sort had, as yet, been put forward, but proposals had been made on the part of Canada; and the colonial allegation was that the obstacle is the stipulation in some commercial treaties, which obliged our Colonies to admit the goods of certain foreign countries at precisely the same duty as they did the manufactures of the United Kingdom. As regards France, it was too soon yet to say what the effect of the new tariff would be. An interesting discussion would probably arise on these questions on Mr. McCormick's paper next week, and on one by Colonel Howard Vincent, in May. It must be remembered that those countries which adopted a high tariff system considered that the advantages it conferred on the agricultural, industrial, and shipping interests, by developing important branches of trade, counterbalanced the disadvantages which they fully recognised in the higher prices of particular commodities.

Mr. GEORGE CLARE said he understood the object of the paper was to induce British manufacturers to take a more rational interest in the subject of foreign exchange; both in theory and practice. Up to almost the time of the Franco-German war, the supremacy of British manufactures was nearly absolute and our manufacturers were able to say to the foreign buyer, there are my goods; you know the quality; the price is so and so; and if you want them you must pay for them by a bill on London; and the foreign buyer had to submit. The English manufacturer was then independent—almost too much so—the only competition he had to meet being that of his own countrymen. But all that was now changed. Great progress had been made in manufactures on the Continent, especially in Germany and Belgium; and the result was, that British manufacturers were now subject to very active foreign competition, and the foreign buyer was now turning round, and, as appeared by the Consular Reports, was beginning to say: There are two price lists, one British and one German. The British one is made out in the English language, in insular currency, which I do not understand, and in English weights and measures, which are unintelligible. On the other hand, the German price list is in my own language, currency, and weights and measures. If the goods are of equal quality, why

should I not give the preference to the one which is so much more convenient. If English makers were to hold their ground, they must adapt themselves to circumstances; and he hoped this paper would have the effect of causing them to give more attention to what must eventually be a necessary condition of their retaining their business.

Mr. MATHESON, in reply, said Mr. Clare had made a criticism on the manufacturers of this country which was often made by those who saw more than the banking and commercial side of the matter. But the answer of the English makers would be that they were manufacturers and not merchants; they left, perhaps unwisely, the commerce to the gentlemen who lived in London and Liverpool, who acted as intermediaries, and provided them with that British sterling against shipment which they so much valued. They thought there should be a subdivision of labour, and that the looking abroad for customers and changing English prices into foreign currency, though very necessary, was not their business. They might be wrong in that, but as long as they kept their factories going they could hardly be expected to alter it. It was not all profit to the German manufacturer that in China, Brazil, and other places he had gone past the Englishmen and given those facilities—sometimes in the way of credit, as well as in the ease with which his invoices could be read; and in some cases the German manufacturer was only now acquiring, at great cost to himself, the bitter experience which the British exporter, or his father and grandfather had acquired long ago. There was a good deal to be said on the side Mr. Clare had mentioned, but there was also something to be said on the other side. He was very sorry to hear Mr. Kennedy say that the United States policy had succeeded with regard to Brazil, and thought that sufficient time had not yet elapsed to enable an opinion to be formed. He held it was a fact that a treaty had been signed, but the success had not yet been proved of a system which was radically unsound. His reference to the West Indies was quite general; he did not refer specially to Trinidad, but Jamaica and Canada were the two countries from which he thought some rivalry might be feared. Where there was so much ignorance on this important subject amongst traders, he hoped that even the slight contribution he had been able to make would prove useful.

The CHAIRMAN then proposed a vote of thanks to Mr. Matheson for his paper, which was carried unanimously, and the meeting adjourned.

Miscellaneous.

CHICAGO EXHIBITION.

The following report has been presented to the Director-General by the Hon. Walker Fearn, Chief of the Department of Foreign Affairs:—

Thirty-eight nations and colonies have official commissions actively at work in the interest of the Exposition. These are—Argentine Republic, Austria, Belgium, Brazil, Columbia, Costa Rica, Denmark, Ecuador, France, Germany, Great Britain, Guatemala, Hawaiian Islands, Honduras, Italy, Japan, Korea, Mexico, Nicaragua, Norway, Paraguay, Persia, Peru, Russia, Salvador, Transvaal, Turkey, British Guiana, British Honduras, Canada, Cape Colony, Ceylon, Cuba, Dutch West Indies, Jamaica, New South Wales, Porto Rico, Trinidad.

The Argentine republic has appropriated $10,000 (£2,000), and will erect a special building. Austria has appropriated $149,100 (£29,820), and a commission of the most eminent men of that country is at work. Belgium has made no Government appropriation, but many of the great manufacturing establishments have applied for space. Bolivia has appropriated $30,700 (£6,140), and will make an interesting exhibit. Brazil, through National and State appropriations, has an aggregate sum of $600,000 (£120,000) for Exposition purposes, and will erect a special building. China has not arranged for any Governmental exhibits, but individual efforts are being made for a good representation. Chili, when the Balmaceda Government was in power, set aside $100,000 (£20,000) for Exposition purposes. The matter is now under the consideration of the new Government. Colombia made an appropriation of $100,000 (£20,000) and will have a complete exhibit, and will erect a special building. Costa Rica appropriated $150,000 (£30,000), and will make a complete exhibit in a separate building. Denmark has given no official notice of an appropriation; a Commissioner has visited this country and secured space for a complete exhibit. Danish West Indies will make a complete exhibit. Ecuador has appropriated $125,000 (£25,000) for a complete exhibit in a special building. Egypt has been granted a concession for a street in Cairo and a complete exhibit in special buildings. France has appropriated $650,000 (£130,000), with a complete exhibit of arts and manufactures. Algeria has a concession for a complete exhibit in special buildings. French Guiana will have a complete exhibit of polished woods; Germany has made a preliminary appropriation of $214,200 (£42,840) for the greatest exhibit ever made by this nation at any World's Fair. Three special buildings will be erected. Great Britain has made a preliminary appropriation of $125,000 (£25,000) for a complete exhibit, and will erect four or five special buildings. Barbadoes has granted an appropriation of $6,000 (£1,200), and will make a complete exhibit. British Guiana has appropriated $25,000 (£5,000), and British Honduras $7,500 (£1,500), for complete exhibits. Canada has allowed a preliminary appropriation of $100,000 (£20,000). There will be a complete exhibit of all British North America. Cape Colony has appropriated $25,000 (£5,000), and there will be a thorough representation of all British South Africa.

Ceylon's appropriation is $70,000 (£14,000) for a

thorough and unique exhibit in a special building, India will have a full exhibit, and probably a special building. Jamaica's appropriation is $20,000 (£4,000). New South Wales, and all the Australian Colonies, have a Commission at work, with Government funds, who have applied for 300,000 square feet. Trinidad has appropriated $15,000 (£3,000). Guatemala's appropriation is $120,000 (£24,000). The Hawaiian Islands will have a complete exhibit in special buildings. Hayti will make a complete exhibit. Dutch Guiana's appropriation is $10,000 (£2,000). The Dutch West Indies have appropriated $5,000 (£1,000).

Honduras has appropriated $20,000 (£4,000).

Italy has made no appropriation, but a Commission is at work, and space has been applied for, by the best artists and manufacturers.

Japan's appropriation is $631,000 (£126,200), for the most complete exhibit ever made by this nation, in special permanent buildings.

Korea will have a complete exhibit.

Mexico's preliminary appropriation is $50,000 (£10,000). The Government Bureau and Commission are collecting exhibits.

Morocco has obtained a concession for a complete exhibit in special buildings.

Nicaragua's appropriation is $30,000 (£6,000).

Norway's appropriation is $53,600 (£10,720), for the greatest exhibit ever made by this county at a World's Fair, with a special building.

Paraguay's appropriation is $100,000 (£20,000).

Persia will have a thorough and complete exhibition from Central Asia.

Peru's appropriation is $125,000 (£25,000) for the most thorough exhibit ever made by this country; there will be a special building.

Russia's Government will make the finest exhibit ever made by the Russian Empire at any Exhibition.

Salvador's appropriation is $12,000 (£2,400.)

Spain will have a complete exhibit in special building. Cuba's appropriation is $25,000 (£5,000).

Sweden will make a complete exhibit, as will also Transvaal.

Turkey's concession is for a complete exhibit in special buildings. Uruguay will have a complete exhibit. Venezuela will make a complete exhibit n special building. Greece will have a complete Governmental exhibit of ancient art.

Madeira's exhibit will be complete, as will that of the Orange Free State, San Domingo, Siam, and the Straits Settlements.

Obituary.

Sir Francis Knollys, Bart., F.R.S. — Sir Francis Charles Knollys, whose death occurred on the 19th ult., was born in 1802, and succeeded his father in 1831 as third baronet. He was educated at Trinity College, Cambridge, and graduated B.A. 1825, M.A. 1828, and was called to the Bar in Lincoln's-inn in 1834. In 1871, he read a paper before the Institution of Civil Engineers, on the "Archimedean Screw-Propeller, or Helix, of Maximum Work," for which he was awarded a Telford Premium by the Institution. Sir Francis Knollys read a paper before the Society of Arts, in November, 1873, on a "Method of Refining or Converting Cast Iron into Iron or Steel," and in 1874 he was elected a member of the Society.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday evenings, at Eight o'clock:—

April 6.—Robert S. McCormick, Resident Commissioner for Great Britain from the World's Columbian Exposition, "The Future Trade Relations of Great Britain and the United States." Sir Douglas Galton, K.C.B.. F.R.S., will preside.

Indian Section.

Thursday afternoons, at 4.30 p.m.:—

April 7.—Dr. J. Augustus Voelcker, "The Agricultural Needs of India." Sir John Strachey, G.C.S.I., will preside.

Foreign and Colonial Section.

Tuesday evenings, at Eight o'clock:—

April 5.—The Rev. John McLean, D.D., "The Red and White Races in Manitoba and the North-West." Sir Charles Tupper, Bart., G.C.M.G., C.B., will preside. The paper will be illustrated by lantern slides, and a collection of Blackfoot and Sioux Indian articles.

Cantor Lectures.

Monday evenings, at Eight o'clock:—

Bennett H. Brough, Assoc.R.S.M., F.G.S., "Mine Surveying." Three Lectures.

Lecture II.—April 4.—*Surveying.*—The compass—Ancient forms of compass—Various forms of miner's dials and theodolites—Use of aluminium for mine-surveying instruments—Supply of light for reading the verniers underground.

MEETINGS FOR THE ENSUING WEEK.

Monday, April 4...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Bennet H. Brough, "Mine Surveying." (Lecture II.)

Farmers' Club, Salisbury-square Hotel, Fleet-street, E.C., 4 p.m. Prof. Wallace, "Agriculture of Modern Egypt."

Scottish Geographical Society (London Branch), 20, Hanover-square, W., 8½ p.m. Inaugural Address by Professor James Bryce, on "The Migrations of the Races of Men, considered Historically."

Engineers, Westminster Town-hall, 7½ p.m. 1. Discussion on Mr. Stephen Sellon's paper, "Electrical Traction and its Financial Aspect."

2. Mr. Reginald Bolton, "The Application of Electricity to Hoisting Machinery."

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Dr. C. R. A. Wright, "Specific Gravities for Practical Purposes." 2. Mr. Adolphe Baur, "Artificial Musk." 3. Mr. F. H. Leeds, "Note on Rosin Oil."

British Architects, 9, Conduit-street, W., 8 p.m. 1. Signor Luca Beltrami, "The Construction of the Central Pillars of Milan Cathedral." 2. Mr. J. Starkie Gardner, "Wrought Ironwork: the Renaissance Period."

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 1a, Adelphi-terrace, W.C., 8 p.m. Professor Bernard, "The Argument from Design."

East India Association, Westminster Town-hall, S.W., 3 p.m. Mr. Herbert J. Reynolds, "The Amendment of the Indian Councils Act."

TUESDAY, APRIL 5...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Foreign and Colonial Section.) Rev. John McLean, "The Red and White Races in Manitoba and the North-West."

Royal Institution, Albemarle-street, W., 3 p.m. Prof. Victor Horsley, "The Brain." (Lecture XII.)

Central Chamber of Agriculture (at the HOUSE OF THE SOCIETY OF ARTS), 11 a.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. H. Alfred Roechling, "The Sewage-Farms of Berlin."

Pathological, 20, Hanover-square, W., 8½ p.m.

Biblical Archæology, 9, Conduit-street, W., 8 p.m.

Zoological, 3, Hanover-square, W., 8½ p.m. 1. Mr. Edgar A. Smith, "The Land-Shells of St. Helena." 2. Mr. F. E. Beddard, "Notes on the Indian Darter *(Plotus melanogaster)*." 3. Mr. Seebohm, "A recently-described Species of Pheasant from Central Asia."

WEDNESDAY, APRIL 6...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Robert McCormick, "The Future Trade Relations of Great Britain and the United States."

Naval Architects (at the HOUSE OF THE SOCIETY OF ARTS), 12 a.m. Annual Meeting. 1. Address by the President. 2. Mr. B. Martell, "On divisional Water-tight Bulkheads as applied to Steamers and Sailing Vessels." 3. Mr. J. I. Thornycroft, "On Steadying Vessels at Sea.'

Geological, Burlington-house, W., 8 p.m. 1. Mr. Walcot Gibson, "Geology of the Gold-bearing Rocks of the Southern Transvaal." 2. Mr. R. G. Mackley Browne, "The Precipitation and Deposition of Sea-borne Sediment."

Entomological, 11, Chandos-street, W., 7 p.m.

Archælogical Association, 32, Sackville-street, W., 8 p.m.

Obstetrical, 20, Hanover-square, W. 8 p.m.

THURSDAY, APRIL 24.. SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Dr. J. Augustus Voelcker, "The Agricultural Needs of India."

Naval Architects (at the HOUSE OF THE SOCIETY OF ARTS), 12 noon. 1. Mr. W. H. White, "Notes on some recent Experiences with H.M. Ships." 2. Commander E. B. Boyle, "A Ram Vessel and the Importance of Rams in War." 3. Mr. F. C. Goodall, "Whale-back Steamers." 7 p.m. 1. Mr. S. W. F. Morrish, "An Approximate Rule for the Vertical Position of the Centre of Buoyancy." 2. Mr. A. F. Yarrow, "Balancing Marine Engines and the Vibration of Vessels."

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Mr. D. Morris, "The Phenomena concerned in the Production of Forked and Branched Palms." 2. Mr. A. W. Waters, "Gland-like Bodies, &c., in the Bryozoa."

Chemical, Burlington-house, W., 8 p.m. 1. Messrs. W. A. Shenstone and C. R. Beck, "Platinous Chloride and its Use as a Source of Chlorine." 2. Prof. Emerson Reynolds, "The Action of Silver Tetrachloride on Substituted Phenylamines."

Society for the Encouragement of Fine Arts, 9, Conduit-street, W., 8 p.m. Colonel Lambert, "Hephaestos, or the Mysteries of Art in the Precious Metals."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. B. A. Whitelegge, "Epidemic Waves." (Lecture III.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. A. Reckenzaun's paper, "Load Diagrams of Electric Tramways, and the Cost of Electric Traction."

Historical, 11, Chandos-street, W., 8½ p m.

Archæological Institution, Oxford-mansion, Oxford-street, W., 4 p m.

Geographical, 44, Broom-street, Manchester, 7½ p.m. Mr. W. E. Hoyle, "Zoology in relation to Geography."

FRIDAY, APRIL 8...Naval Architects (at the HOUSE OF THE SOCIETY OF ARTS), 12 noon. 1. Mr. A. Denny, "Some Notes on the Strength of Steamers." 2. Mr. W. Hok, "On the Transverse Stability of Ships, and a Rapid Method of Determining it." 3. Mr. J. H. Heck, "Notes on Experiments with Inflammable and Explosive Atmospheres of Petroleum Vapour." 7 p.m. 1. Mr. R. E. Froude, "On the Theoretical Effect of the Race Rotation on Screw-Propeller Efficiency." 2. Mr. J. G. Liversidge, "Performance of Three Sets of Engines belonging to the Second-class Cruisers recently added to H.M. Navy, as calculated from the Full-Power Steam Trials."

United Service Institution, Whitehall-yard, 3 p.m. 1. Captain Sir Alfred Jephson, "On the Royal Naval Exhibition of 1891." 2. Major L. Edie, "The Arts Section of the Naval Exhibition."

Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting, 9 p.m. Professor W. E. Ayrton, "Electric Meters, Motors, and Money Matters."

Civil Engineers, 25, Great George street, S.W., 7½ p.m. (Students' Meeting.) Mr. R. J. Durley, "Some Forms of Petroleum Engines."

Astronomical, Burlington-house, W., 8 p.m.

Junior Engineering Society, Westminster-palace-hotel, Victoria-street, S.W., 8 p.m. Mr. H. G. Dempster, "Suspension Bridges, with a description of the Donyang River Bridge, Assam."

Institute of Architecture, Science, and Art, Dundee. 8 p.m. Mr. W. D. M'Kay, "The Art of the Low Countries."

Clinical, 20, Hanover-square, W., 8½ p.m.

Physical, Science Schools, South Kensington, S.W., 5 p.m. 1. Mr. William Akroyd, "Note on a Law of Colour in its relation to Chemical Constitution." 2. Mr. Walter Baily, "On the Construction of a Colour Map." 3. Mr. William Gleed, "A Mnemonic Table in connection with Electrical Units."

SATURDAY, APRIL 9...Royal Institution, Albemarle-street, W., 3 p.m. Dr. J. F. Bridge, "Dramatic Music from Shakspere to Dryden." Lecture III.

Botanic, Inner Circle, Regent's-park, N.W., 3.45 p.m.

The Telegraphic Address of the Society of Arts, and of the Royal Commission for the Chicago Exhibition, is "Praxiteles, London."

Journal of the Society of Arts.

No. 2,055. Vol. XL.

FRIDAY, APRIL 8, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

CANTOR LECTURES.

The second lecture of the course on "Mine Surveying" was delivered by Mr. Bennett H. Brough, Assoc.R.S.M., F.G.S., on Monday evening, 4th inst.

The lectures will be printed in the *Journal* during the autumn recess.

Chicago Exhibition, 1893.

MEETING OF THE ROYAL COMMISSION.

A meeting of the Royal Commission was held on Wednesday, 6th inst. Present:—The Attorney-General, M.P., Chairman of the Commission, in the chair; Sir Frederick Abel, K.C.B., F.R.S., William Anderson, D.C.L., F.R.S., Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., Michael Carteighe, R. Brudenell Carter, F.R.C.S., Lord Alfred S. Churchill, B. Francis Cobb, Sir Philip Cunliffe-Owen, K.C.B., K C.M.G., C.I.E., Major-General J. F. D. Donnelly, C.B., James Dredge, Francis Elgar, LL.D., Sir Douglas Galton, K.C.B , D.C.L., F.R.S., Thomes Hawksley, F.R.S., Alexander B. W. Kennedy, F.R.S., Charles Malcolm Kennedy, C.B., John Biddulph Martin, John Fletcher Moulton, Q.C., F.R.S., Wyndham S. Portal, Professor William Chandler Roberts-Austen, C.B., F.R.S., and Sir Saul Samuel, K.C.M.G., C.B., with Sir Henry Trueman Wood, M.A., as secretary.

AGRICULTURAL COMMITTEE.

A meeting of the Agricultural and Food Products Committee was held on Monday afternoon, 4th inst., at 12, Hanover-square. Present: The Earl of Feversham, President of the Royal Agricultural Society, in the chair; R. Bannister, The Earl Cathcart, Major Craigie, Alfred Darby, Walter Gilbey, Captain Heaton, Colonel Sir Nigel Kingscote, K.C.B., Lieut.-Gen. Michael, C.S.I., Lord Moreton, John Thornton, Dr. J. Augustus Voelcker, Sir William Williams, Bart., Sir H. Trueman Wood, Secretary of the Royal Commission, and Ernest Clarke, Honorary Secretary.

Proceedings of the Society.

APPLIED ART SECTION.

Tuesday, March 29th, 1892; Alfred Gilbert, A.R.A., in the chair.

The paper read was—

THE DECORATIVE USES OF SCULPTURE.

By E. Roscoe Mullins.

There are two recognised ways of looking at the art of sculpture—the historical, and that included in the study of archæology. These two aspects of the art are more alike than at first might be assumed, and the illustrations for the survey of it from the one aspect would serve equally well for the other; for the "science of man's handiwork in the past," which archæology is, includes sculpture, and, in a limited degree, is indeed identical with it.

But there is a third way in which the art can be studied, which, though not so comprehensive as the other two, yet will be found to include most of the important works that have been executed in the past, and to embrace within its fold most of the aims of the sculptor himself, and that is, the decorative aspect of the art.

So important is this view, that I can scarcely understand an ancient sculptor, whether of Egypt, Assyria, or Greece, deeming it necessary to make any subdivision of the art at all beyond it. To him, all, or nearly all, sculpture would be undertaken for purposes of decoration, and though he might allow for a few exceptions, he would not accept it as the rule as we do now, that sculpture should be

executed independent of its destination, and without any direct object in its design.

The same would apply to the sculpture of the great Gothic age of the 11th to the 13th centuries, and also to that of the Renaissance of the 15th, 16th, and 17th centuries.

When the term sculpture was used in the past, it applied to decorative sculpture in particular, but we, however, have unfortunately accustomed ourselves to apply the term "decoration" only to the mere filling up of space with work destitute of any meaning, and without direct purpose beyond that of ornament. The misuse of the term probably dates from the 18th century, in the times of Louis XV., when society was thoroughly disorganised, and was undergoing a great upheaval. At that time art was but an additional luxury to the few.

The importance of a meaning to all the higher forms of decoration is one which cannot be too strenuously insisted upon; and I think, by reference to the examples that I intend to bring before you at the end of my paper, that you will agree with me that, in former great ages of the art, this was always the guiding principle of the sculptor. The false and limited view of decoration held by us of to-day is constantly fostered by the sight of isolated pieces of sculpture, that were formerly parts of a whole, but have been detached from their places (whether by violence or necessity it is not within my province here to discuss), and placed permanently in our museums. Thus, we lose the connection that once existed between them and their surroundings, and accustom ourselves to look at them, and enjoy them too (that I fully admit) purely as separate works, just as one might a book taken down from its shelf; and we are as apt to infer that the pieces of sculpture are as independent of their surroundings as the contents of that book may be to those of its neighbours alongside it, or to the mouldings of the shelf on which it was placed.

The great advantages that we enjoy through the establishment of these museums—and they are quite a modern institution — must not deaden us to their possible evil. As the late Professor Jevons has forcibly pointed out, "the collection of the articles is accidental, and to realise the true meaning and beauty of an object, the spectator must possess a previous knowledge of its historical bearings and a rare power of imagination, enabling him to restore it ideally to its place." "Who, for instance," he continues, "that sees some of the reproductions of the mosaics of Ravenna hanging high upon the walls of the Museum at South Kensington, can acquire therefrom the faintest idea of the mysterious power of those long lines of figures in the Church of St. Apollinaris." Since Prof. Jevons wrote this, the Science and Art Department has done much to supply this deficiency, whereever possible. I do not mean to say, but that in decorative sculpture, much of what we call pure ornament must, even if it had originally any meaning, be now detached from it in its manifold applications to modern buildings; the egg and tongue moulding (whether derived or not from the ancient Lotus, as a writer lately has sought to prove) the Ionic and other capitals, and such like varieties of form, cannot have any definite meaning to us, but serve only to afford pleasing lines to the eye, or to accentuate a space by their richly broken up surfaces; but these, for this very reason, should be looked upon as decoration of a less important order, and by no means representative of decoration as a whole. Wherever possible, an idea should be allowed to assert itself, in however simple a form, and take the place of the oft-repeated panels of ornament, adapted from some architect's stock-book of designs, which now do duty on so many buildings of all descriptions and of whatever character, be they banks, warehouses, residential flats, hotels, or churches, and which have no interest of their own apart from their easy flow of line.

But dwelling with especial emphasis, as I am doing, upon the decorative side of sculpture, yet I do not wish it to be assumed that all sculpture must necessarily be of that character alone; and, though feeling strongly the importance of looking at my art from this point of view, I still do not wish to ignore the existence of what is now called sculpture proper. "Freistehende," free-standing, as the Germans call it. But I think the line is a very fine one that can be drawn between these two kinds, and it is difficult to formulate an absolute definition, to include the one and exclude the other.

It would, for instance, be a matter of difficulty to decide—nor shall I attempt to take up your time by the too curious inquiry—whether the Chryselephantine statue of Jupiter was decoration to the temple of Olympia, or the Athena to the Parthenon; but of this we may be tolerably sure, viz., that fitness of place in these instances would have been the first question to be considered, quite as much and even more so as with works that are unquestionably deco-

rative, such as the pediment, metopes, and frieze of the outer walls. We may be sure at least of this, that they were not ordered of the artist merely to satisfy the desire of the public for some such statue, and then, as an after consideration, placed in the above-mentioned temples as the best place available.

If only to bring this truth more vividly home to us now, it would be worth spending a little time in turning our thoughts back to the ancient world. For whether the work may be classed as decorative or not, no important statue or group should ever be considered apart from the position it is destined to occupy: the modelling, scale of proportion, the treatment generally should be all adapted to its final position, and also, and this is equally important, to the light that it will then receive. That which applies with such force to the important temple statues of Greece applies equally so to the sculpture in cathedrals and churches; and any figure, even when completely free-standing, and meant to serve a definite religious purpose, as in Catholic churches, should be kept in harmony with the general design of the building, even though it cannot be said to be directly a part of its decoration. Speaking of the religious figures used freely for purposes of worship, an amusing incident lately occurred in Paris. Some sculptors there are said to have agitated against a certain manufacturer, who turns out a quantity of Virgins and Saints for this purpose, but who does not employ sculptors for the woik; the figures were described as wooden effigies with great staring dolls' eyes, dressed in gaudy robes of real material. The manufacturer maintained they were fairly good works of art, though some of them, he admitted, were atrocious! I think this illustrates very forcibly one class of work executed apart from decoration—the ridiculous side of it if you will, but, nevertheless, typical. There is another branch of the art, very different from that just described, but equally non-decorative This is work that depends upon its technique only for the merit that it may have: work generally small in character, such as statuettes of light and graceful fancy, of which the lovely Tanagra terra-cottas may be cited as good examples, which can be turned lovingly about, between finger and thumb, and the varying play of light enjoyed on their finely modelled surfaces. But this is a class of work that appeals really to the artist himself, rather than to the general public, for to understand and fully to enjoy the technique, more knowledge is required than it is possible for the general public to possess; and no excellence of workmanship alone will ever make a popular art.

But this delightful class of work need not detain us here, for beautiful as it is, it cannot seriously be considered as representative of the art of sculpture. "C'est magnifique," perhaps, "mais ce n'est pas la guerre." Moreover, this aspect of art has dangerous pitfalls all round it, and the articles produced may easily become mere *bric-a-brac*, and serve only to "count for garniture and household stuff," as Browning puts it.

I am confirmed in the higher view that I am taking of the decorative side of the art, and justified in looking at it thus seriously, by Professor Ruskin, who says, (in his "Aratra Pentelici,") that "the energy of growth in any people may be almost directly measured by their passion for imitative art, namely, for sculpture or for the drama." With this idea before him, he speaks of the decoration of a building—the Duomo of Pisa—as containing "the germ of a school of sculpture, which was to maintain, through a subsequent period of 400 years, the greatest power yet reached by the art of the world in description of form and expression of thought."

With such authority before me, I may be allowed to claim the utmost importance for decorative sculpture; and it is this view of the applied art that I wish to keep before you, and about which I should like to say a few more words, before submitting some examples from works of the past.

To deserve this measure of importance, decorative sculpture should first be in touch with the nation's demands, that the people may find illustrated on the walls of, and within their public buildings, in a language that all can read the stirring events of their time, the glorious deeds of their heroes, the history or legends associated with the growth of their cities, and thus that thoughts and sentiments may be roused within them at the sight of these buildings, in accordance with the object for which the building is erected, be it a hall of justice, a municipal building, houses of parliament, or a cathedral.

This is not a question for the sculptor alone; indeed, he can do little until the demand is made by the nation; and, no more than the architect can he produce the work if not commissioned. But the whole nation must be with him, first, in feeling the need for such true decoration, thus creating the de-

mand for it, and then by affording a healthy stimulus to the artist by wise appreciation.

It is significant that Goethe, in his appeal to German sculptors, where he is at pains to suggest subjects for their skill, assumes, as a matter of course, that they must be such as would appeal to the nation as a whole. Writing in 1817, the chief subject in his mind is necessarily war and its consequences, the victor and the vanquished, and he alludes to the great difficulty the modern sculptor has, over his ancient brethren in Greece, in the matter of costume. This no doubt is true, but it is a difficulty that can be overcome. Happily for us, there are other and more important subjects than war to interest and rouse us now, and I only take Goethe's instance to show the guiding principle underlying his choice of subject to enforce the truth of it home to us; for, simple as it is, it is yet wholly forgotten by the public at large, and sculpture can not be said to be a means of national expression at all in this country, with the one exception—through portraiture. The English people do like to have statues and busts of their great men; but this means of expression Goethe does not even allude to, and neither do I consider it to be one; it more often takes its place with other dismal funeral obsequies that are arranged on the death of an important personage, and is the easy means of unloading our minds of duties to the memory of the departed. Certainly it is oftener this, than an interpretation into stone of the virtues that may have distinguished him, or the good deeds done by him in some noble cause. The individuality of a man is, I admit, worth portraying, but even this is not achieved in the colossal isolated figures of which we are so fond; the very necessities of the case, the size of the statue required, and its position, prevent the sculptor from giving prominence to the individuality of a man, that could be given if placed in a building, or in a niche nearer the eye. But even the individuality of a man is not the most important fact to accentuate in a memorial, for this bears the same relation to the bigger forms of sculpture that biography bears to history; at the best it belongs to the smaller rather than to the larger assortment of facts. The Parthenon pediments—one illustrating, by a mythological idea, the importance of Athens as an inland rather than a seaboard city, and the other, the birth of its patron goddess; or, again, the tomb of Pope Julius II., by Michael Angelo, with its attendant figure of Moses—have a deeper significance in them than would have been apparent if Pericles and his counsellors had been depicted on the former, and the Pope and his cardinals on the latter.

But, although this may be the higher view of art, it would yet be a great step gained if we could possibly bring this national craving for the effigies of our great men, which, undoubtedly is laudable enough in itself, within the fold of decoration; and, by linking it to architecture, to give the figures meaning where they now have so little, detached and isolated as they at present stand.

No doubt the chief obstacle in the way would be, the great desire that people have to give sufficient importance to this class of work; the only form of sculpture, as I said before, that seems to have a permanent hold on the nation. As important, I suppose it would not be, if incorporated in some scheme of decoration, but it would be receiving only similar treatment to a picture-portrait, which is rarely placed on an easel in the centre of a room, but within a frame and hung on the walls. Some of this importance therefore might be sacrificed to the general fitness of things, and the æsthetic perception of what is really the most beautiful. The question of modern costume is one that, I think, should alone condemn our custom of placing huge portrait statues in our squares and open spaces. It is impossible to make a standing figure so dressed, interesting from all points of view, the back must be shapeless, even if the front is tolerable; a back view of a frock coat is a terrible object, especially when placed on the top of trousered legs. Ridicule is cast upon the unfortunate sculptor, when really the blame should rest on the people for ordering these huge effigies, and placing them where they stand. An equestrian statue is a very different matter, for the lines of a fine horse can be enjoyed at any angle, even if the rider, on account of his costume, should not be so interesting in himself, though in this particular he is not at such a disadvantage as his standing *confrère*, for the sharper lines of his position allow more play for folds, and for the costume generally to express the form beneath. We cannot expect to find as picturesque a hero as a Colleoni, but Marochetti's Cœur-de-Lion and Foley's Outram show us how isolated works of this character can be placed, and can be enjoyed quite apart from their surroundings, though Marochetti's figure certainly owes something of the happy effect produced to the fine background afforded by the Houses of Parliament; even as the statue of James II. by Grinling Gibbons does

to its position in the small square behind Whitehall. No doubt in all matters of reform, it is well in the first place to find out and acknowledge the ruling tendency of a nation's characteristics, and certainly ours in reference to sculpture is to give importance to Iconic forms over that of others. Thus, what I wish is, to take advantage of this tendency, and so erect our memorials that they may not only do honour to our heroes, but also be monuments in harmony with our fine public buildings; and let the buildings of the future themselves be planned with a view to them.

I may be allowed to point out that the outer niches of St. Paul's Cathedral are still empty, and it would not be the first time in our history that niches of our important cathedrals have been filled with kings and statesmen—civil heroes as well as church dignitaries. Take, for instance, Wells Cathedral, where are placed kings, knights and ladies, amongst the various bishops and other ecclesiastics; a sign, says Lübke, of "our early political consciousness and historical feeling." It would thus be in harmony with our own traditions if we dedicated these niches in St. Paul's to men who have left their mark on their age, and whose memory the age is desirous of preserving.

It would be pardonable in me, perhaps, if I looked a little ahead to see, in the now rapidly developing recognition of the worth of women in public affairs, another source of difficulty to the future sculptors, if their only chance for distinction lies, as it does now, in portrait statues in isolated positions in the open; for women will demand statues too; and difficult as it now is to make a male standing statue in modern costume suggestive of the figure beneath the garb, still greater will the difficulty become, when dealing with the fashionable dress of the other sex.

Let us, for all reasons then, be prepared for the erection of the coming memorials, by having homes made for them in buildings that are now being constructed, so that architect and sculptor may combine together and work out, each in their several ways, one common idea. To do this would be to return to our best traditions; it would emphasise the object of a building, and by accentuating the past deeds of great men in the scene of their labours, serve as a stimulus to coming generations.

With this simple principle in our minds, we shall be better able to understand how it is that the sculpture of the end of the last century, and the beginning of this, has so little of permanent value or interest to us, although the sculptors were, individually, often men of great ability; one or two, indeed, such as Roubiliac, of exceptional ability. One feels that the works of men like Bacon, Banks, Wilson, Gibson, and others is misplaced, or, rather, as if they were not intended for any particular place at all, but were executed for a museum, and for any odd corner where there was room. They do not touch us as they should, in spite of, as in those by Roubiliac, their great merit in execution. But not only are they not decorative in treatment, they are not representative of the leading thoughts of that age. I suppose the two leading ideas of that time were the establishment of our Colonies and the abolition of slavery. Yet neither of these great subjects inspired our sculptors then; at least, I can think of no important work that would typify them. When not engaged upon portrait statues, their skill was exercised in creating a Venus, a Diana, or a Cupid, which, at the most, could only rank as conventional classical imitations, not especially beautiful in themselves, and possessing for a future age none of that archæological interest that work, true to the thoughts and aspirations of its own time, must always have.

The chief exponent of this conventional art was John Gibson: to me there is a special sadness in looking back on his life and works. We are conscious now of the weakness of his work; but, even in my student days, most art lovers that I came across esteemed him as the finest sculptor of the day. It is not that fashion has shifted from classical standards to the freer development of the Renaissance—lovers of art will always love the best Greek sculpture—but it is the want of aim in his work, and their isolation from the thoughts of the time, that has brought this neglect. There is a warning note to sculptors in the words of his will, by which he bequeathed his casts to the nation:—"Yes, I do feel," he wrote, "that the collection of my models, seen together, would be of use to the young sculptors as to style." Now, not a soul but the very curious goes near them; and the works represent a splendid gallery of an art that is dead, because created apart and away from the needs of the time and the sympathies of the nation.

Flaxman's work was a glorious exception to this conventional art, and redeems this period from the wholesale condemnation that would otherwise be justly meted out to it. His reliefs are especially decorative, and when placed effectively, as I have seen them, they have

great power in accentuating the purpose of a building. Those that I refer to are panels from the Lord's Prayer series, and are let into the wall at the east end of a church, alone occupying the space, where they serve as true sermons in stone, without need of comment or words of any kind. Such I maintain to be instances of true religious decorative art. The inevitable result of detaching sculpture from architecture, and looking upon the art as independent of other arts, and capable of stirring sentiment alone and unattached, is this harping back on the old masters, and following in grooves dug out by them, working, that is to say, according to theories, rather than up to required needs.

Theories must always be cramping and dangerous if meant as a guide to future production. In sculpture it has proved itself to be especially so, because the art has been such a happy hunting ground for the critic and conoisseur. Theories are only interesting as gathering up and focussing what has been done, but not at all in deciding upon the form future work shall take. Of all theories, that based on the search for beauty is perhaps the most destructive of all original talent, and yet it is the one most frequently set up. Even Goethe, with his width of view and knowledge of the many sidedness of life, when commenting on Lessing's Laocoon, says, "The former (that is sculpture) had to confine itself within the limits of the beautiful," and again, "Sculpture labours for external sense, which is satisfied only by means of the beautiful." An artist, it seems to me, who is seeking for beauty, is as a man seeking for happiness, as the one aim in life; a desirable end to attain, but never attained by directly planning or searching for it. And it is the same with the attainment of beauty in sculpture; the end is only reached by having some more definite and tangible object in view, while the mere search for beauty only leads to imitation and trite conventionality. But let the immediate purpose of our work be the desire simply to tell a story and adapt it to the place that the work is to fill; then, in this happy filling up of space, the element of beauty will possibly be there without our striving especially for it; at any rate the work will be stamped with our own individuality, and that is an element always of interest.

Not only is it pernicious to the originality of the worker himself to be perpetually seeking only for the beautiful, but it deprives the work of an element, the value of which, it is true, is more appreciated by future races than at the time of execution. I refer to what I have already alluded to as the archæological side of art. How much have we not learnt of previous inhabitants of the world simply by the knowledge gleaned from their decorative sculpture! Besides well-known instances, such as the Egyptian reliefs, which give us the whole range of the nation's pursuits, take the case of the early and little-known race of the Hittites. What is known of their previous history and the knowledge of their far spreading dominion have been derived chiefly from the study of their sculptural reliefs. The presence of the mural crown and the double-headed eagle, in association with a certain ever-recurring decorative pattern, and the top-heeled boot, the high peaked turban, the short high girded sword, &c., these and other features all point, when found on slabs scattered over Asia Minor and elsewhere, to the presence of that early race. Again, much remains yet to learn concerning the Mexicans, when the curious hieroglyphics of their huge monoliths have been deciphered.

It is certain that this interest at least will be wanting to future antiquaries, if it is found that our works refer to a mythology foreign to our country, to heroes and gods not believed in by our race, and merely copied because they were nude. "What's Hecuba to him, or he to Hecuba," may well then be their cry. If we cannot invest our works with any lofty ideas, we can at least be true to the conditions of the time; and this we should much more readily be, if sculpture were the result of a demand from the public instead of what it so often is—the outcome of a chance action seen by the sculptor in a model in his studio, to which work he afterwards appends some learned Greek name.

While speaking of the danger of disconnecting sculpture from architecture, I should like to refer to two tendencies of the present day. One affects the art itself, and is, it appears to me, as pernicious to its free development, as the old-fashioned desire to produce only something beautiful, and that is the influence upon sculpture of the sister art of painting, which necessarily follows from the importance given to the yearly exhibitions, especially at the Royal Academy, in which the preponderence of painters to sculptors is as nine to one. Truthfully modelled surfaces and the literal rendering of nature naturally have more weight with a painter than with a sculptor, for, in painting, imitation of nature cannot be carried to too great an excess, and the

most thoroughly realistic work will still bear the impress of art on its canvas; but it is not so with sculpture, for a plaster cast from life will give the exact imitation without any art at all. The result of this painter-influence leads often to the neglect of design, composition, and all thought of suitability to any given place. The other evil to which sculpture is always liable, if disconnected with architecture, is to become the property of the few, instead of belonging to the nation as a whole.

In treating of the art from a decorative point of view, I have purposely kept my mind on the architectural side of sculpture, as the most important form of decoration, but I would wish it understood that I apply the term decorative sculpture to the covering of any surface that needs decoration, be it what it may, from the walls of palaces and municipal buildings, to fire-dogs, knockers, clocks, lamps, mantel-pieces, jewellery, &c. Of course these latter can never attain to the importance of architectural sculpture, for the reason above mentioned, that they must, for the most part, belong to the individual and not to the nation, but otherwise they merit as much thought and care as surfaces that are more pretentious. In this paper, I cannot do more than allude to them, but the mere mention of the above list shows the enormous field open to the sculptor, and the very wide range of his art as a decorative one. Neither do I think it necessary to draw any fine line between useful and purely ornamental articles. The æsthetic enjoyment of a fine knocker is, it is true, not in rapping with it, but the excellence of the artistic design and execution need not interfere with it as a useful article. I have often wondered, by-the-way, who buys those marvellously carved meerschaum pipes that one sees exposed in tobacconists' windows, and still more, who smokes them. This is one of those instances, I think, when we may exclaim with the poet that "Beauty unadorned is adorn'd the most." I must confess I can give no reason, save as Shylock puts it, "a lodged hate and a certain loathing" I have to the "adorned" article in question.

The difficulty that arises with regard to making jewellery really artistic and worth the sculptor's attention, is caused mainly by the fiend fashion; for it is impossible to justify fine work on an article that is decreed to be out of date a few months after it is made. The round brooch has to give way to the long, the broad bracelet to the fine and thin, quite independent of the workmanship and beauty that one or the other may possess. Yet great painters and sculptors in the past learnt their craft, and gained most of their valuable experience, in the goldsmiths' workshops; and our artists might do so again, if this paralysing influence were once removed.

I will now place before you some illustrations of the subject I have dwelt upon, begging you to remember that, as I have not put myself forward as one stating any new thing, neither must you expect to find amongst the lantern slides many that are not familiar to you. My object in showing them is that we may look upon our old friends in their right light, and class them under their right name—as decorative sculpture—thus in imagination bringing them out of the museums, and placing them back in the positions they formerly occupied on buildings, or in some way intimately associated with architecture.

Slide 1 and the following one are taken from part of a panel cut on the walls of the king's palace at Nineveh, and they require no explanation from me for introducing them as works of high-class decorative order. These alabaster reliefs decorated the inside of the apartments, and in this fact lies the explanation of the treatment of the relief; for the desired effect is attained with the least disturbance to the general evenness of the wall; there are no strong contrasts of light and shade (for no parts project much over others) as would have been permissible if the works had been intended for out of doors, and the spectator could have stood some way back to enjoy them.

It cannot be too strongly insisted upon that all treatment of relief is but a means to render nature nature-like under given conditions; the resemblance to nature being always the ultimate test of the work. So this flat relief was not intended to look flat, but the depth was chosen by the sculptor, as the condition enforced upon him by the circumstances, his chief aim being to render, as truly as he could, these battle and hunting scenes so dear to the Assyrians.

One of the interesting features of Assyrian sculpture is the wonderful facility with which the sculptors portrayed animals: lions, buffaloes, wild horses, mules, gazelles, and stags: though lions are the true heroes of Assyrian art. These animals are drawn with a vigour and naturalness that have never been surpassed, and the bold, even realistic manner in which they are conceived, compares favourably with

the best work of any time. To us the odd thing is that, when dealing with man, their sculpture is so vastly inferior; a constrained conventionality is always apparent, in strong contrast to these carefully-studied animals. This peculiarity has been explained by reference to the political despotism under which the people lived, which made it imperative to the sculptor to forego the study of the individual for fear of interfering with the importance of the king. Thus, curbed in the representation of man, the artistic taste of the people—due, it should be stated, to Babylonian influence—found perfect expression in another direction.

Slide 3. This figure, and the three below from the Parthenon, formed part of the eastern pediment of that building. The figure of Theseus, or, as it is now thought to be, the Mountain God, symbolising Olympus, was placed at the extreme end, and is thus the least important of the whole series in the pediment.

It is a wonderful triumph for decorative art that this figure, destined for comparatively an insignificant position, should hold, as it does, undisputed pre-eminence amongst the nude figures that have come down to us, even as the accompanying "Fates" hold sway amongst draped figures. The difference of scale is, of course, purely accidental.

With the Greeks, one sees that the human figure, unlike Assyrian art, was paramount; but tradition nevertheless was responsible for the evident uniformity of type that is aimed at. Individuality, as we understand the word, found no place in Grecian art; the faces of their deities were handed on through centuries, improved and made more human with each succeeding age, but they can be traced back to the scraped wooden images of the 7th and 6th centuries B.C. These gods were local, and were as present to the Greeks, as the Madonna and saints were to the people living in the 13th century of our era.

The subject of the whole pediment, of which these figures formed part, was the "Birth of Athena from the head of Zeus," a favourite subject of Athenian art.

Slide 4. This illustration is from perhaps the finest metope of the same building, and will be equally familiar to you all. Here, again, a dominant idea pervades the whole series, that of an allegorical representation of the earliest conflict between civilisation and brute barbarism, symbolised by the contest between the Lapithæe and the Centaurs. This panel forms an admirable answer to the statement sometimes made, that the Greeks did not depict strong action: one of a crop of errors that has grown out of an imitation of the antique, without its life and traditions.

Slide 5. This and the following I have selected from the famous Panathenaic frieze, to illustrate the happy way in which a realistic subject may be treated from a decorative point of view, and with due regard to the peculiar position of the frieze and the reflected light, upon which it was solely dependent for its effect. The subject is the "Delivery of the Peplos," a robe made by certain Athenian maidens, and at stated times placed on the old statue of Athena Polias in the Erectheum. In this procession all classes of the Athenian people took part, headed by their magistrates and other leaders.

Slide 6. It is interesting to note the difference made between the conception of gods and men. Here we have Hermes, Poseidon, Demeter, and Hephaistos, their greater size (allowed for by their sitting posture) and the absence of marked costume, alone apparently distinguishing them from the riders. The story is thus made manifest, but the whole brought together by treatment; and we are enabled to see in the metopes an allegorical representation of a myth, and in this frieze a realistic rendering of a historic fact, both treated as to be part of the decoration of the same building.

We have copied the relief, or the same kind of relief, on two of our buildings—the Athenæum Club, and the gate at Hyde-park-corner, leading into the park—quite ignoring the conditions that compelled the Greeks to choose this flat treatment. Placed high and exposed to the full light of day, as they are with us, there was absolutely no necessity for this kind of relief, and the result is a mere piece of tracery.

Slide 7. I am introducing this and the following panels to show the peculiar archæological interest that sometimes attaches to decorative sculpture. They are Indian works, but their style of execution, so thoroughly different from ordinary Indian work, show, in a marked degree, Grecian influence, the inspiring source of which dates back to the Greek invasion of India, that we know took place under Alexander the Great. The art of India is of much more recent date than was once supposed, and the first knowledge we have of Indian sculpture is after this Alexandrian invasion—about 325 B.C. This one is taken from a monument at Gaudara, in the Punjab, executed about the first century of our era, representing the death

of Buddha. The scene is depicted between two pilasters with Corinthian capitals, so especially Greek is the character; it is for this reason I am introducing it to you. When we think of the abnormal rather than the normal characteristics of Indian sculpture as a rule, and its delineation of the human figure as a body with seven arms, three heads, &c., the difference between it and these panels will be clearly marked. The small panel above is worthy of notice for the lively little Cupid at the right hand corner, which is characteristic, we should have thought, by its *abandon*, rather of the Renaissance than Greek decoration.

Slide 8. This illustration also shows the Græco-Roman style of ornament; the garlands and wreaths, resembling those on the entablatures of the Temple of Vesta, in Tivoli, which was erected B.C. 70.

Slide 9. The next representation shows some walls with battlements, and a doorway with jambs, such as were used in Etruscan doors (B.C. 400 or 500). This story is thoroughly Indian, depicting some legend of Buddha.

Slide 10. From a historical point of view, it would be ridiculous to bring this work before you, following so immediately on the last, thus jumping from the 1st century to the 13th. But I am merely introducing a few isolated examples of fine periods of art, to show how decorative sculpture can be applied to noble uses, and that it was as decoration that the chief sculpture of the past had been employed. This panel is from Rheims Cathedral, and illustrates, as well as any I know, the charm of the Gothic order. There is something especially beautiful in the slender and delicate proportions of the figure. Looking at this illustration, we can understand the writer when he says that, in the 13th century art, more of the good than the evil of the world was depicted, more of its beauty than its ugliness. We see now, too, the tendency in Gothic art to the vertical, instead of the horizontal lines, characteristic of Greek work.

Slidn 11. This figure is from the Chapter-house of Westminster, and represents the Annunciation. It has the same slender proportions as the preceding ones. Gothic sculpture is more dependent upon its surrounding architecture than is the Greek, and its effect is marred to a greater degree when seen away from it, as is the case here, where the figure has been photographed in a museum.

Slide 12. This lovely illustration is from a glazed terra-cotta by Luca della Robbia. I have not been able definitely to locate it, but it is probably from some church in Florence. The treatment is charmingly tender and natural, and the simplicity of the composition enhances its beauty. It is interesting to see in this frequent adoption of the subject of the Madonna and Child, the chivalry of the mediæval world asserting itself; "the chivalric, mystic love of the Middle Ages."

I wish especially to refer to this work, as typical of Luca della Robbia, for I suppose no sculptor has more effectively rendered this beautiful Madonna worship of that age. As Lübke puts it, "he appears unwearied and inexhaustible in the delineation of a calm nature, brightened by loveliness of expression."

It is very suggestive to compare the Madonna of the 15th century with the Greek Venus, both typifying, as they do, the national conception of divine love; one is youthful, in the full perfection of form, with the calm contentment of expression of one who is perfect and beautiful in herself, and for herself alone; the other suggests maturity, coupled with a fineness, rather than a fulness of form, as seen also in Donatello's Madonnas, but the self-satisfied look of complacency of the Greek goddess is replaced by the sweet sense of motherhood, with its entire self-abnegation and self-effacement; for the woman's thought is centred in her child.

Slide 13. This illustration is from one of the twelve spandrels, also by the same sculptor, that are placed to each arch of the Foundling Hospital in Florence, and that form such beautiful decoration to the building. Each little figure is enveloped in swaddling clothes, every one differing from the other in position and expression.

14. These decorative panels are well known, and need no comment of mine to lend appreciation to them. Jean Goujon is one of the first sculptors, whose name would occur to us when thinking of decorative sculpture. We see here how he adapted the figure for decorative purposes to fill up his spaces; and the masterly treatment and skilful arrangement of light and shade, afforded by the contrast of the nude and drapery, give us a sense of pleasure whenever we look at them. The originals, designed for the Fontaine des Innocents, are now in the Louvre, but casts of them may be seen at the South Kensington Museum.

Slide 15. This illustration carries our thoughts on to modern times; for Michael Angelo was essentially a modern sculptor, who attempted something more than to embody the purely emotional character of the Middle Ages. The

struggle of the time—life, with its inward experiences and sorrows and outward unrest—are well exemplified in the intensity of expression and violence of the position of all his figures. He was not one who himself lived outside the storm and stress, but took an active part, as we know, in the political life of the times.

There is scarcely one of his works that might not be considered decorative, with the exception of the "David," that owed its existence, as we know, to an awkwardly shaped block of marble.

This figure called "Evening" formed part of the tomb of Lorenzo de Medici. It is a splendid decorative work, though it is difficult to understand it by the title given; it is rather, like the figure of Lorenzo himself, an emanation of the great sculptor's brain, independent of particular subject, but which, with its companion figure of "Morning," appeals to us by its grandeur and dignity, as embodying the spirit of restless activity and deep contemplation, so essentially characteristic of the sculptor. We see the wide scope that there is for decoration dependent only on the genius of the artist, and the consequent uselessness of rules for its guidance, when we note the works of sculptors such as Michael Angelo and Luca della Robbia. The art of the latter is based upon realism, as seen in the panel from the Foundling Hospital in Florence that I showed before, where the babies are all wrapped in swaddling clothes, as could be seen in any house at that day, while here we have an artist's powerful ideal conception untrammelled by any thought of costume.

Slide 16. From sculpture of our own time, I may refer to that of Alfred Stevens, whose work is amongst the finest we have, and is again almost entirely decorative. This plate represents one of the side groups of his masterpiece, the Wellington monument in St. Paul's. To those who have thoroughly realised that sculpture should, for the most part, be connected with architecture, his works must appeal with great force. The pity is that, placed where this fine group is, against a window, the effect of it is quite lost; indeed, to enjoy it and the whole monument, we must go to the South Kensington Museum, the home of the decorative arts, where successful attempts are now made to show the art in its own architectural surroundings, as far as possible. Seen from the other side, this group before us, "Truth taking the tongue out of Lying," is not so pleasing, for the sight of a wrenched tongue is unpleasant, and the close imitation n stone of a poetic thought rather revolting.

On the other side of the monument, the group "Valour and Cowardice" is a more pleasing subject, and simpler in thought, whilst equally fine in execution.

Not only was it in the higher fields of decorative sculpture that Alfred Stevens so well succeeded, but in the minor forms, such as for mantels, fireplaces, grates, &c. He was a perfect master in the management of ornament; nothing in sculpture was too great or too little for him, but all he did was directed to definite ends.

Slide 17. There are two or three more illustrations I should like to show you before I finish, and these are of French work. The first is M. Dubois' group of "Charity," that occupies one of the angles of the monument to General Lamoricière. It is important for our purpose, because it shows the possibility of going to real life for our subjects for decorative art. This is not merely an abstract idea of Charity, that might have been used in Græco-Roman times, or even at the Renaissance, but we see that the figure, by her face and dress, is taken from a woman of this time and the nation, to which the work belongs; and thus would speak as directly to the most unlearned now as an Aphrodite or Minerva did to the ancient Greeks. It will be seen that the drapery, as well as the type, is of to-day, as the stuff used is not the thin, clinging material worn by the Greeks in their hot climate, but a thick, woollen texture, suitable to our more northern latitude.

Slide 18. This figure is from the opposite of the same monument, and represents Know-Knowledge or Wisdom. I show it because it indicates again a departure from ancient ways, as it is a successful attempt to depict age. There are as few important works of the ancients representing age as there are those representing children. They restricted their art to the ripeness of mankind or the fullness of youth. With us the whole gamut of age is free for portrayal, even as our views of life, its purposes and aims, are wider; and we feel there is as much dignity to be derived from the one as abstract beauty from the other.

Slide 19. The last illustration I shall show you is by M. Dalou, a sculptor well known in this country, for the many excellent works he executed when here, and the impetus he gave to the art generally. This is from a large bronze panel, placed in the Chamber of Deputies in Paris, and represents the Declaration at Versailles in 1789 by the Third Estate (afterwards the National Assembly) that henceforth

it, and not the king, would represent the nation:—"Go, Monsieur," says Mirabeau to the deputy of the king, "tell those who sent you that we are here by the will of the people, and that nothing but the force of bayonets shall send us hence." Truly a stirring scene and affording a difficult problem to solve by the decorative artist. But what better decoration to a Chamber of Deputies could there be than such a subject!

To sum up the few ideas I have ventured to express: I maintain first of all that sculpture must in the main be decorative, allied chiefly to architecture, and speaking to us from its walls.

When thus linked with architecture I would have it free within these limits, to develop the individuality of the artist, and the characteristics of the time; I should wish it to be as true to latter day life as possible, and thus be in touch with the age. If the artist has imagination, and can see through the surface of life into the hidden mystery of things, let him by all means represent it; if not, let him portray life as he sees it, and we will hope that the necessities of the conditions under which he works, that is, his architectural surroundings, will tone down any too strongly developed tendency to realism. Why, even our foe, the frock-coated gentleman, might not pose amiss, when twisted into a miserere or a gargoyle!

Such are the few thoughts that seem to me to be important to us sculptors at the present day, and their importance to us means importance to the nation at large; for, if art is to be of any use at all, it must be in touch with the nation. As Mr. Frederic Harrison has lately said, when speaking of the great Gothic period of art, and the memorials it has left to us, "These vast temples are the creation of generations of men, and the embodiment of entire epochs; and he who would know the Middle Ages should study in detail every carved figure, every painted window, each canopy, each relief, each portal in Amiens or Chartres, Rheims, Bourges, Lincoln, or Salisbury, and he will find revealed to him more than he can read in a thousand books."

DISCUSSION.

Mr. HUGH STANNUS said, knowing Mr. Mullins's admirable little Primer on sculpture, he had expected to hear a very interesting and instructive paper, and he had not been disappointed. What Mr. Mullins had been pleading for throughout seemed to be the necessity that sculpture should have that connection with the monumental forms of architecture which it had in the beginning, and from which it was only divorced by passing fashion. There were two other points which struck him as being important in the paper, one was where Mr. Mullins pleaded that all sculpture should tell a story, that it should not be merely the running up and down the scale of forms, but that there should be Storiation as an element, not merely æsthetic decoration. He believed all would agree in the view—that whatever in decorative work appealed not only to the sense of beauty but to the intelligence of man, and the associations of the past stored in his memory, would be thereby very much more worthy of attention than mere egg-and-tongue or Roman scroll repetition. Then, secondly, there was a point of still greater importance, the contemporaneousness of sculpture. Mr. Ruskin had said, in words which were so fine that he hesitated to spoil them by quotation, that every artist who had powers confided to him by a beneficent Providence, was responsible for the use of the talent to his own day and generation, to represent the facts of his own day in the costume of his own day—not to seek the facts in the beginning of old forgotten mythologies or in the toga or chlamys of classical times—but that he should seek the events that were worth remembering of his own day, the deeds of heroism that were done every week in London, in England, or under British rule, and should clothe the figures in the costume of the time. This was a strong point made by Mr. Mullins, and he thought many would sympathise with him in it. He had referred to the difficulty of dealing with modern costume, and no doubt it was a difficulty. No one contended that the back view of a dress-coat was interesting, but inasmuch as the interesting part of every friend was his face and not his back view, so the sculptor would be justified in treating the subject as was shown in the noble statues against the old cathedrals, in which the figures showed their front view, while the back view was hidden by the building against which they stood. Then he had pleaded for utilisation of the niches of St. Paul's, and there are many other niches which are crying out for occupants. Unfortunately, when committees colleet subscriptions for the memorial of some great man, they are not content that the statue should be put up to form one among a number of others; but they always want a special site given to it in some open space. When the time came that all the open spaces are full and can accommodate no more, probably they would think of these open spaces in buildings, and he felt quite sure it would be a very proper use for them. The paper throughout was very full of interest and instruction, and he begged to thank Mr. Mullins, personally, for the pleasure he had given.

Mr. LEWIS DAY said he also had listened to the paper with great interest, and in the main agreed heartily with the author, but not when he spoke of the harm done by theories, and by seeking after the

beautiful; there he must protest: he entirely dissented from that view. Theories might easily be pushed too far, more especially if they were adopted at second-hand; but without theories or something very like them—call them convictions if you liked—he did not see how an artist could complete himself. He was old-fashioned enough to believe in the beautiful —as he thought, after all, the author himself did, for when it came to illustrating his paper, the examples shown were all beautiful; they went to show that the sculptor, Assyrian, Greek, or Italian; Jean Goujon Alfred Stevens, modern Frenchman, or whoever he might be, not only sought after the beautiful, but found it. Mr. Mullins had, it was true, guarded himself, in one instance, by speaking of "only the beautiful," but no one in his senses contended that an artist should seek nothing more than beauty in his work. If he were a man as well as a sculptor he would have something to say; and, inasmuch as he was an artist, he would put that into beautiful shape. An artist must seek beauty—a sculptor must seek beauty of form; from sculpture which was not beautiful the speaker prayed that we might be delivered.

Mr. REGINALD BLOMFIELD said there were one or two points he felt a little disposed to quarrel with. Mr. Mullins insisted that the sculptor should deal with what he called the leading ideas of time, but he thought that would be rather difficult to carry out, because no one was very clear as to what the leading ideas of the time were; some thought it was making money, and others thought other things, but it would be difficult to lay down any general principle. It seemed to him much wiser to leave it to the man himself. The main thing he had to do was to express what was in him. If a man had anything to say, it did not follow he could say it, but if he tried to say it, and said it with any degree of success, his work was sure to be interesting, and if he did it well, in beautiful form or colour, it would take a high place as a work of art. Again, this point of contemporaneousness, as it had been called, seemed a little awkward too. He really did not see why a sculptor should be limited to our exceedingly hideous dress if he chose to work in some other way. That seemed to hang on to the idea raised by Mr. Mullins as to historical sculpture. Mr. Mullins referred to the Hittites; he had an exceedingly hazy idea who the Hittites were, but when they flourished there certainly was no such thing as written history, no such thing as a penny paper. When the Assyrians produced their magnificent sculptures, no doubt it was very proper for them to represent the lions and lionesses slain by the king, but it was not the least necessary to do that now-a-days when the Prince of Wales went out hunting, because there were plenty of people to record it in the legitimate way in writing. He thought it was rather a failure as a rule both in sculpture and painting when an attempt was made to record current events. However, the subject of the paper was sculpture in relation to architecture, and it was undoubtedly a burning question of the day, in relation both to sculpture and architecture, how the two could work together, and what was the common ground on which they could meet. What struck him in London was the enormous quantity of sculpture about and its exceeding badness. In Shaftesbury-avenue there were a great quantity of houses, and he did not think there was a single piece of good sculpture in any of those new buildings, although there was a great quantity of it. There was one building which struck his eye very prominently, plastered all over with figures modelled in terra-cotta, turning themselves inside out, standing on their heads, eating their tails, and doing all sorts of things; but there was no meaning in it. It might be all very pretty, but, it seemed to him, that any intelligent person who took a chisel and hacked the face of the material, would get just as valuable an effect with regard to the architecture of the building as was accomplished with all those arabesques, or whatever they might be. He had seen the same thing in another important building, whose face was simply bespattered with this sort of rubbish, though, in the same building, there was some very beautiful work by a sculptor, as opposed merely to the ornamental carving. The work of that sculptor was very beautiful, and seemed to him to add much to the value of the building. He spoke as an architect, and did not see why architects should not resolutely set their faces against this stuff, and all merely conventional ornament; and, when they had the chance of having money spent on sculpture to concentrate their effort on one point, see that the workmen had something to say, and that the work was done by a competent man. He was afraid they did not know enough about each other. Architects did not know enough about sculpture and modelling—and consesequently, did not understand sufficiently the point of view from which the sculptor went to work. On the other hand, sculptors did not know enough about architecture in the best sense. There were of course brilliant exceptions. Alfred Stephens certainly showed immense genius in the Wellington monument, which was a great architectural work, and he did not think anyone else could have designed it; and their distinguished Chairman also had done great work in this way. If sculptors would occasionally give architects a hint, it would be much to their advantage; and sculptors, on the other hand, might perhaps learn a trifle or two from the architects.

Mr. W. S. FRITH thought everyone in the room would agree in the main with what had been put forward in the paper, and it was much to be hoped that the view expressed by Mr. Blomfield would prevail amongst architects. If it did, that would be certainly a very great step in the direction they were all desiring, the proper application of sculpture, and the proper use and display of it. On the side of sculpture, he feared that many of the evils complained of were largely due to the number of sections in which it was split up,

some of which were hardly supposed to belong to it at all. A little time ago anything really connected with architecture was scarcely looked upon as sculpture, and sculptors confined their energies to producing busts and memorial statues, most of them of a very bad order. If sculpture were looked upon a little more as being the art of using form as a means of expression, they would come to the point of which Mr. Blomfield spoke, in which architecture and sculpture really touched one another. He feared no prescription could be laid down as to the costume in which sculpture of this day or that day should be worked. Sculpture belonged to all time. The statues of the Greeks were as fresh now as they were in their days, but they were not in rigid adherence to the costume of the people.

Mr. HOWARD INCE said one or two points had especially struck him in the paper: one, where Mr. Mullins mentioned the fact that ancient, or mediæval, or Renaissance sculptors and painters were accustomed to study, and had all their early training in the goldsmiths' shops. That, he thought, accounted for the decorative quality of their work. They were thoroughly trained in decoration, and that was something which was not born to one; it required long and severe training; and, because those men had that training, they succeeded as they did. It was a great thing to have such a paper as this read; and he hoped it was only the beginning of a new era, in which decorative work would take a high place; and be recognised, if not as the chief, at any rate as a very high branch of the sculpture and art generally of the country.

Mr. MULLINS, in reply, said the differences of opinion which had been expressed were not many, but he could not soften down anything he had said. First, with regard to Mr. Day's remark about beauty. He hoped it would not be assumed that because he said beauty ought not be the chief force in the sculptor's mind, that therefore he was not to seek for beauty. There should be no one abstract idea of beauty. Anyone who had read Lessing's "Laocoon" would understand his allusion. He did not assume that each man had his own way of looking at beauty, but that his own standard of beauty should apply to everybody was what he objected to. It was necessary to have convictions, but one man's conviction would not be the conviction of another, and he should like that each man should represent his idea of beauty quite independently of the idea his neighbours might have of it, certainly not the one idea that he should go to a book or standard for, but that he should seek for it in his own character. Mr. Blomfield had referred to the difficulty of portraying leading ideas, and of course it was difficult, but the historian succeeded, and why not the sculptor. The sculptor should bring in the historian to help him, and he might arrive at the general bearing of the period. He did not mean merely the last twenty or ten years, but the sculptor could study the times, and attempt, if he had the opportunity, to portray what had happened in his own country. It was difficult to get an abstract view of particular events, but that was the great thing to aim at. It was said that it would be difficult to carry out these leading ideas, and that it would be better for the man to do what was in him; but he thought it was possible to do the two. He agreed in what had been said about architectural ornament. It was rather the corollary of the paper. All useless filling up of space, which had done so much damage to decoration, was objectionable, and he could not see why there should not be more meaning put into it. He could not help echoing the thought and words of Mr. Stannus as applicable to some of the work of the Chairman representing death, the poppy, and the doves. That was the sort of thing they ought to seek for in sculpture.

The CHAIRMAN then proposed a cordial vote of thanks to Mr. Mullins for his paper.

The vote of thanks was carried unanimously.

FOREIGN & COLONIAL SECTION.

Tuesday, April 5, 1892; Sir CHARLES TUPPER, Bart., G.C.M.G., C.B., in the chair. The paper read was "The Red and White Races in Manitoba and the North-West," by the Rev. JOHN MCLEAN, D.D

The paper and report of the discussion will be printed in the next number of the *Journal*.

SEVENTEENTH ORDINARY MEETING.

Wednesday, April 6th, 1892; Sir DOUGLAS GALTON, K.C.B., D.C.L., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Chorlton, Thomas, 32, Brazenose-street, Manchester.
Hill, Lieut.-Colonel John, R.E., Poona, India.
Holzapfel, Albert C., 57, Fenchurch-street, E.C.
Lowenfeld, Henry, 31, Lowndes-square, S.W.
Ryder, Charles, Gledhow-hill, Leeds.

The following members were balloted for and duly elected members of the Society:—

Kirby, Frederick Hall, Union Club, Trafalgar square, W.C.
Meacham, Charles S., 62, Earl-street, Maidstone, Kent.

The paper read was—

THE FUTURE TRADE RELATIONS OF GREAT BRITAIN AND THE UNITED STATES.

By Robert S. McCormick.
Resident Commissioner for Great Britain from the Columbian Exposition.

Part I.—Historical.

In preparing the address which I am about to deliver, in response to the invitation with which you have honoured me, it has been my endeavour not to forget that I am a member of this Society, as well as the representative of the World's Columbian Exposition. I have read somewhere—I think in an article in *Lippincott's Magazine*—that "we (meaning Americans) are very critical of the foreigner, and we are very conceited about ourselves. In this we are not peculiar. Love of country walks hand-in-hand with prejudice. Where such does not exist the passion is apt to be wavering and wan. Nevertheless, it is well now and then to reverse the lens of criticism, shorten the focus, and turn it upon ourselves. No one can for a moment doubt, of course, that we are worth more than anybody else, but it is a healthy process for every kind of truth to be put occasionally upon the defensive." Not only is this true of Americans, but it is true of every nation on earth, and the process above recommended is equally as good for others as for Americans. It is also important that we do justice to others and not form our opinions of them upon limited knowledge, or select isolated actions as a foundation for our conception of their character.

Beginning with "No good can come out of Nazareth," and coming on down through the "Heathen of the Jews," "the barbarian of the Greeks," "Greek faith," "perfidous Albion," "rascally Dutch," "British greed," "a nation of shopkeepers," "Turkish horrors," "Russian barbarities," "Bulgarian atrocities," "German infidelity," "French morals," to Mark Tapley's "American Eagle," and "Despotism, anarchy, and Corruption in the United States of America," and the "Brand of Cain in the Great Republic," the last two named being the titles of rather recent articles in English magazines of good repute; prejudice, the child of ignorance, has thrown these upon a screen as the prominent if not the leading characteristics, negative or positive, of the place and nations to which they have respectively been applied. Pride, self-conceit, self-interest, oftentimes a false conception of self-interest, too often lead to a false judgment of men and things, and this is the "pride that leadeth to destruction." Do not think that I am going to read you a homily on the virtue of humility, or preach you a sermon on its converse, the sin of pride. I only wish in the beginning to ask you to hear what I have to say, with your judgment free so far as humanly possible, from the influence of tradition, which oft-times beclouds the facts of history, as well as for the time being at least, free from your own conception right or wrong, of the interests which it is your right and duty to uphold and protect in such manner and by such means as may seem best to you, according to others the same right and recognising for them the same duty.

The trade relations between the United States and Great Britain—the subject upon which, at the request of your secretary, I have undertaken to read a paper—cannot be properly understood unless we go back at least 200 years, and consider the events which gave birth to and fostered England's commercial supremacy throughout the world, and the great mechanical inventions which developed this supremacy to its splendid magnitude. If there were time, and this the proper occasion, it would be interesting to begin with that early prototype of England, Pheonicia, "the smallest and yet the richest nation of antiquity, whose ships and sailors were the finest in the ancient world," and follow westward the rising sun of commerce as its bright rays illumined and enriched in turn Carthage, Greece, and Rome, to its eclipse in the dismemberment of the Roman Empire; and then with its returning light in the Middle Ages witness the signing of the first Treaty of Commerce 796 A.D., between Charlemagne and Offa, king of Mercia, by which document the former granted his protection to English traders from that district: showing that you were already sowing the seed of future policy and future commercial supremacy; on through the upbuilding of Venice (upon a site as impossible for a city as that of Chicago was pronounced to be by a United States Government official), with salt and fish as her only articles of export, but made the great *entrepôt* of trade between the continent of Europe and the East, securing the exclusive right of selling the mineral salt of Hungary and Croatia—an effort at monopoly, then as now, being the order of the day—and becoming, like England later on, the great carrier of the world, employing a commercial fleet of 3,000 merchant vessels, of from 10 to 100 tons burden, and in addition 40 war ships, each carrying 100 men, a prototype, in minia-

ture indeed, of the England of to-day, of which you are so justly proud. Genoa and Milan also had their day, and then the Italian cities whose commercial wealth had brought them political independence, succumbed to internal dissensions, the discovery of the sea-route to India contributing to their fall. Were there time I would like to dwell upon the history of the Hanseatic League, with its "factories" or branches at Novgorod, Bergen, Bruges, and London. The last named was abolished after frequent attacks upon it by London mobs in 1597. "Our own merchants," says an English authority, "had become too strong to brook a foreign rival in their midst." "Its primary object was to afford mutual protection to the cities composing it against the Continental piracy that had infested the German and Baltic seas ever since the coming of the Northmen."

The work which it did for the improvement of mediæval society, the growth of industry, and the development of commerce, entitle it to more than a passing notice in the history of civilisation. Having played its part, it disappeared as the foundation-stone is buried beneath the classic pile which attracts and rivets our admiring gaze. In the same way rose and fell the Confederation of the Rhine and the Suabian Confederation. If we glance at a map of Europe in the Middle Ages, says an authority, "we shall find that by far the greatest centres of manufacture were in the north-western corner of the Continent—the portion now occupied by Belgium, part of Holland, and a small part of the North of France. Linen and woollen fabrics were chiefly made there. The eastern counties of England, especially Norfolk and its great centre Norwich, and the western counties of Wilts and Somerset, also made a good deal of woollen cloth. The main branch of manufacture in the south of Europe was that of silk, which was made in the north-east corner of Spain, in the district round about Barcelona; in France, round about the great centre of Lyons; but, more than anywhere else, in Italy, round Genoa, Milan, Venice, Florence, and Naples. The raw wool, for making cloths of all kinds, was sent to Flanders from two main sources—England and Spain; but English wool was superior to Spanish for fine cloths; and, moreover, in most cloths, Spanish wool required to be mingled with English before it could be worked up. England and Spain, then, provided the raw material, and Flanders did the manufacturing part of the woollen cloth trade. Wool, indeed, in the Middle Ages, was the basis of England's wealth, and paid for many of her wars."

In the 10th and 11th centuries, the Counts of Flanders were wise enough to promote actively the welfare of their subjects, and the growth of industry; and it was from this time that the country became famous throughout Europe for the weaving and fulling of cloth. Arras, Cassel, Tournai, Valenciennes, St. Omer, Rousselaere, Contrai, Yprès, Lille, Ghent, and Bruges all became famous and prosperous cities, the four last named leading the rest, and having each of them as many as 40,000 looms constantly at work, largely supplied with wool from England. The city of Ghent had, in 1400, 80,000 men capable of bearing arms, the weavers alone furnishing 20,000. Bruges, with its canal to the sea, was practically a port, until the canal was blocked up by Maximilian of Germany, in 1482, when Antwerp came to the fore, being a port of great importance, and coming in for a large share of the commerce with India, around the Cape, and later on with the New World, the discovery of which, with all that it signifies, we will celebrate at Chicago, in 1893. With its rich neighbours, Antwerp fell a prey to the persecutions of the Spaniards, being twice sacked by them, and London stepped into the proud position of the great emporium of the western world, and has held it now for about three centuries. And this brings us across the channel, and within the confines of the "tight little island," whose place to-day in the world of commerce, with its sun nearly at the meridian, should make her take rank with the "Seven Wonders," and in comparison dwarf to pigmies the giants of earlier days. "Although England is now such a commercial nation, she by no means occupied such a position in the Middle Ages. Her manufactures were far more outshone by those of Flanders and the Italian cities; her commerce was almost insignificant compared with that carried on by the mighty merchants of the Hansa, or by the enterprising traders of Genoa and Venice; nor did England begin to gain the greatest maritime and commercial position which she now holds till the reign of Elizabeth (1559-1603), shortly after the Reformation and the discovery of the New World, and of the new route to the West Indies. Trade and commerce had been probably more flourishing in England under the Romans, and it is interesting to note corn [or, as we would say in the United States, grain] was an im-

portant article of export, for in 359 [according to the historian Zosimus] 800 vessels were sent from Britain with corn to succour the Roman colonies on the Rhine, which had been plundered. But the history of commerce remains almost a blank until the days of Alfred, who encouraged trade by cultivating relations with foreign princes, sending embassies as far as India; and also, in 887, founded the English Navy. Athelstane, following in the footsteps of Alfred, encouraged foreign trade by issuing a decree that 'every merchant who fared thrice over the sea with a ship and cargo of his own should be worthy of thane right,' *i.e.*, should rank as a nobleman; and when we come to the reign of Ethelred II. (979-1016), we find mention of a law regulating the tolls on ships putting in at the harbour of Billingsgate, which was, even then, a fish-market; of trading vessels coming from Flanders, Normandy, and of German merchants, called the Emperor's men, who were allowed to trade in London. Finally, as the country became more settled, wool was exported in ever increasing quantities."

From this page in your history, over which we are now glancing, we see that England at this time stood in the same relation to Flanders as the United States held to England at the beginning of the present century, and for some years thereafter that relation still existing to a great extent. You were exporting raw material to Flanders, and taking back in in exchange therefore the product of Flemish looms. Though Henry I., in 1110, endeavoured to encourage domestic textile manufacturers, by establishing a colony of Flemish weavers in Ross and Pembrokeshire, it was some centuries before you could make into fine cloths the wool which your flocks yielded. During the "golden days of good Queen Bess, our competitors," says Gibbins, the author of that excellent short work, "History of Commerce in Europe," from which I have freely quoted as an English authority, "the Netherlands were severely crippled by the Spanish persecutions. But England did not benefit merely by the cessation of their competition; she received at the same time hundreds of Flemish immigrants, whose skill and capital greatly aided our home manufactures. Germany, also another competitor, was soon after utterly ruined and exhausted for a long period by the terrible Thirty Years' War [1619-1638], and with Germany and the Netherlands laid low, English manufacturers had little to fear. And at this very juncture the King of France, Louis XIV., did us an enormous service and his country an enormous loss, by driving out of his country the pick of his manufacturers and artisans—the Huguenots, or French Protestants, 50,000 of which came to England with a capital among them of £3,000,000. All the nations of the earth were kept warm with the wool from England. The victories of Crecy and Agincourt were very brilliant, but they certainly never could have been gained unless England had had the means of putting a strong army into the field, and the means of doing this was provided by wool."

In 1331, Edward III. invited John Kemp, of Flanders, and other weavers, dyers, and fullers to come over and settle in this country under his favour and protection, and then was the beginning of your manufacture and export of cloths, though it was a long time before the export of cloth became at all important. So, too, foreign merchants taught you to undertake foreign trade; foreign merchant fleets largely monopolising the carrying trade until early in the 16th century, the "Merchant Adventurers' Company" secured their charter in 1505.

It would be needless for me to recount the struggle in India, between the Portuguese, the French, the Dutch, and the English. I will only remind you that the Portuguese led the way, the Cape route having been discovered by Vasco de Gama four years after Columbus discovered America, though, as Sir George Birdwood tells us in his interesting Handbook to the British Indian Section at Paris, in 1878, Necho had accomplished this voyage with a Phœnician fleet twenty-one centuries before. It was nearly one hundred years afterwards, in 1582, that the first Englishman, Captain Stephens, sailed round the Cape to what is now your Indian Empire. It is interesting to mention here, to show the relative growth of your shipbuilding and commerce in three hundred years, that "in 1593 a Portuguese ship of 1,600 tons burden was captured, being the largest ship yet seen in England."

In the New World, the discovery of which we are now about to celebrate in Chicago, Spain had a complete monopoly until almost the end of the 15th century, the other European powers not seriously turning their attention in that direction.

From this it will be seen that other nations were the pioneers in discovery and commerce, although it was left for the Anglo-Saxon to develop and secure the wealth which soil, mine,

and forest would only yield to the talismanic combination of brain and brawn. Results have shown what race are the possessors of this combination, in the highest degree. Spain explored her new colonies in the west with only one object, the acquisition of gold and silver—with a minimum amount of labour. We must leave unopened the history of the period intervening between the decline of Spanish power, and the establishment of the English in the North American Continent, and the foundation of the Colonies which afterwards became the thirteen original States, only mentioning the fact that "here as in India England was almost the last to enter upon a colonial career." Toward the middle of the 17th century, England had taken rank as a manufacturing nation, and was exporting in considerable quantities manufactured articles, cloth mainly. During the Commonwealth also the sugar industry in the West Indies began to flourish and great fortunes were made out of it. But the carrying trade between the West Indies and America and England was still largely in the hands of the Dutch, and the English Government made an effort "to remedy this state of things in a manner which demanded special attention," says Gibbins, "by the passage of a law known as the Navigation Acts of 1651". These Acts declared that no merchandise, either of Asia, Africa, or America, except such as should be imported direct from its place of growth or manufacture in Europe should be imported into England, Ireland, or Scotland, or the English Colonies, except in English-built ships. The ships must, moreover, belong to English subjects, be managed by English commanders, and have at least three-fourths of the crew Englishmen; and these laws continued in force until the present century, 1825.

These Navigation Acts, as says the English authority from which I am freely quoting, were a bold declaration of what afterwards became England's avowed commercial policy; protection against foreign competition. In this connection, and following out the line which I laid down in my opening pages, I wish now to place before you briefly for your unprejudiced consideration, the aspect in which other nations have viewed England's commercial policy down through the 340 years which have elapsed since the Navigation Acts were passed, these Acts remaining in force, as said above, as late as 1825. It is necessary for me to do this, as many of your fellow-countrymen, if not fellow-members of this Society, have been harsh, not to say severe and unjust in their criticisms of customs laws passed at Washington—whether wisely or unwisely it is not for me to say—in the interest of American industries, as viewed by the majority in Congress voting for them. Some of your fellow countrymen, if not of your, I should say, our fellow-members, forget in these criticisms that at Westminster your law makers have ever stood ready to protect, nay, more, to advance by heavy subsidies, the interests of the commerce and industries of Great Britain, by legislative enactment. Listen then, with patience, to a little more history before I undertake to picture to you the future trade relations between Great Britain and the United States.

Sir Donald Mackenzie Wallace has told you in his "Russia" how England's commercial policy is viewed in that country, in the following words:—"Great Britain is at present in the position of a successful manufacturer who has outstripped his rivals and has awakened amongst them a considerable amount of jealousy and envy. To justify these feelings a peculiar economic theory had been invented. England, it is said, has become by her *politique d'exploitation*, the great blood-sucker of less advanced nations. Having no cause to fear competition, she advocates the insidious principles of free trade, and deluges foreign countries with her manufactures to such an extent that native industries are inevitably overwhelmed. In the pride of their hearts the manufacturers and merchants of Manchester and London may exclaim—using the quaint old words of the poet Waller:—

> "Gold, though the heaviest metal hither swims;
> Ours is the harvest where the Indians mow,
> We plough the deep and reap where others sow."

Thus all nations pay tribute to England, but this cannot last for ever. The fallacies of free trade have been detected and exposed, and the nations have found in the beneficent power of protection a means of escape from 'British thraldom.' So much for Russia."

The same or similar views are widely held in the United States, and endorsed by many of our public men irrespective of their opinions as to the wisdom of our tariff laws.

In a work published a few years ago, one of our leading statesmen said:—"To be entirely free, trade must encounter no obstruction in the way of tax, either upon export or import. In that sense no nation has ever enjoyed free trade. As contradistinguished from the theory of pro-

tection, England has realised freedom of trade by taxing only that class of imports which meet no competition in home production, thus excluding all pretence of favour or advantage to any of her domestic industries. England came to this policy, after having clogged and embarrassed trade for a long period by the most unreasonable restrictions, ruthlessly enforced, without regard to the interests, or even rights, of others. She had more than 400 Acts of Parliament regulating the tax on imports, under the designation of 'tonnage and poundage' adjusted, as the phrase indicates, to heavy and light commodities. Beyond these, she had a cumbersome system of laws, regulating, and, in many cases, prohibiting the exportation of articles, which might teach to other nations the skill by which she herself prospered."

"When, by long experiment and persistent effort, England had carried her fabrics to perfection; when, by the large accumulation of wealth and the force of reserve capital, she could command facilities which poorer nations could not rival; when, by the talent of her inventors, developed under the stimulus of large reward, she had surpassed all other countries in the magnitude and effectiveness of her machinery, she proclaimed free trade, and persuasively urged it upon all lands with which she had commercial intercourse. Maintaining the most arbitrary and complicated system of protection, so long as her statesmen considered that policy advantageous, she resorted to free trade only when she felt able to invade the domestic markets of other countries, and undersell the fabrics produced by struggling artisans, who were sustained by weaker capital and by less advanced skill. So long as there was danger that her own marts might be invaded, and the products of her looms and forges undersold at home, she rigidly excluded the competing fabric, and held her own market for her own wares. England was, however, neither consistent or candid in her advocacy and establishment of free trade. She did not apply it to all departments of her enterprise, but only to those in which she felt confident that she could defy competition. Long after the triumph in free trade in manufactures, as proclaimed in 1846, England continued to violate every principle of her own creed in the protection she extended to her navigation interests. She had nothing to fear from the United States in the domain of manufactures, and she, therefore, asked us to give her the unrestricted benefit of our markets in exchange for a similar privilege which she offered to us in her markets. But on the sea we were steadily gaining upon her, and in 1850-55 were nearly equal to her in aggregate tonnage. We could build wooden vessels at less cost than England, and our ships excelled hers in speed. When steam began to compete with sail, she saw her advantage. She could build engines at less cost than we, and when, soon afterwards, her shipbuilders began to construct the entire steamer of iron, her advantages became evident to the whole world. England was not content, however, with the superiority which these circumstances gave to her. She did not wait for her own theory of free trade to work out its legitimate results, but forthwith stimulated the growth of her steam marine by the most enormous bounties ever paid by any nation to any enterprise. To a single line of steamers, running alternate weeks from Liverpool to Boston and New York, she paid $900,000 annually, and continued to pay at this extravagant rate for at least 20 years. In all channels of trade where steam could be employed she paid lavish subsidies, and literally destroyed fair competition, and created for herself a practical monopoly in the building of iron steamers, and a superior share in the ocean traffic of the world. But every step she took in the protection of her steam marine, by the payment of bounty, was in flat contradiction of the creed which she was at the same time advocating in those departments of trade where she could conquer her competitors without bounty. With her superiority in navigation attained, and made secure through the instrumentality of subsidies, England could afford to withdraw them. Her ships no longer needed them. Thereupon, with a promptness which would be amusing if it did not have so serious a side for America, she proceeded to inveigh through all her organs of public opinion against the discarded and condemned policy of granting subsidies to ocean steamers. Her course in effect is an exact repetition of that in regard to protection of manufactures, but as it is exhibited before a new generation, the inconsistency is not so readily apprehended nor so keenly appreciated as it should be on this side of the Atlantic. Even now there is good reason for believing that many lines of English steamers, in their effort to seize the trade to the exclusion of rivals, are paid such extravagant rates for the carrying of letters, as practically to amount to a bounty, thus confirming to the present day (1884) the fact that no nation has ever been so persistently and so

jealously protective in her policy as England, so long as the stimulus of protection is needed to give her the command of trade. What is true of England is true in greater or less degree of all other European nations. They have each in turn regulated the adoption of free trade by the ratio of their progress towards the point where they could overcome competition. In all those departments of trade, where competition could overcome them, they have been quick to interpose protective measures for the benefit of their own people."

That the above views are not held by foreigners alone is shown by an article which appeared in your own *Pall Mall Gazette*, a representative of high-class journalism in Great Britain, on June 9th of last year. The same article gives reasons which are historical for the decline in certain lines of British exports:—"The fact that Bombay yarn is supplanting the Manchester article in China was pointed out by the Director of Imperial Maritime Customs four or five years ago. It was found that the Bombay yarn, woven into cloth, had more durable qualities—so it may perhaps be said that Manchester millowners have only themselves to thank for the diminished demand for their goods in this part of the world. They did not give the Chinaman the kind of yarn he wanted. The history of cotton-milling in India is curious in many ways. When the East India Company first traded in the eastern seas, Indian cotton fabrics were without a rival in European markets. The beautiful muslins of Dacca, which were famous when Babylonian and Assyrian kings ruled Western Asia, were among the wares first brought to England by the old East India Company. In 1787, according to Sir George Birdwood, the value of the imports of these muslins into England was estimated at 30 lakhs of rupees, say £300,000. But the invention of the mule jenny in England was presently followed by a cry for the protection of the British manufacturer. A heavy duty was imposed on all Indian cotton goods, and the manufacture of Dacca muslins was killed. But India was to have its revenge. In 1857, the year of the Mutiny, the first steam-loom mill was opened in Bombay. In 1878, there were 58 cotton mills at work in India. In 1890, there were 114 mills, with nearly 3,000,000 spindles; and Indian goods, as we have seen, compete with English manufactures in the markets of China, Africa, and Western Asia. Nor is it easy to see where the development of this industry will stop. Labour is cheap, the staple is grown on the spot, and the native capitalist is just as keen as any Englishman to push his wares. He cannot, of course, compete as yet with his English rivals in the manufacture of the higher kinds of cotton goods, and the 'shortness' of the Indian fibre is still a great difficulty; but the limit of production, both in quality and quantity, is very far from being attained, and English cotton goods must in the future yield still more to the Indian article." Your own Carlyle said that "free trade was the most intense nonsense that ever provoked human patience. The people of Australia were quite right to protect their industries and teach their young men trades, in complete disregard of Parliamentary and platform palaver. No nation ever got manufactures in any other way."

From the passage of the Navigation Acts, down to the close of the last century, you will find on your statute-books every phase of protective legislation which the minds of man could devise; home manufactures were forbidden in the American colonies; their woollen industry was suppressed in 1719; all iron manufactures were forbidden; even colonial hatters were not allowed to send hats from one colony to another. Perhaps it was at this time that he was driven into such a state of mind that "mad as a hatter" became a proverb. Lord Chatham said, in a speech in Parliament, that "the British colonist of North America had no right to manufacture a nail for a horseshoe." But the end of the 18th century brought with it not only the independence of the United States, and a political revolution in France, but also an industrial revolution in England, little, if at all, less far-reaching in its results than the other two events, which will for ever hold such a prominent place in the history of the world; though no great national monuments have been raised to the men whose genius worked this peaceful revolution, and gave to the world the steam-engine, the spindles, and the loom, which placed the most comfortable clothing in reach of the poorest, and, at the same time, laid a large section of the foundation of England's wealth, and political, as well as commercial, greatness. It was these inventions which enabled England to clothe the nations of Europe at large profit to herself, while the latter were engaged in destructive wars.

Some idea of the industrial revolution brought about by these inventions, and of the power of the enormous engine which they placed in England's hands for crushing out all

competition in the struggle for commercial supremacy, may be arrived at from a statement made by Edward Baines, in his "History of the Cotton Manufactures," published in 1835, that the "150,000 workmen in the spinning mills produced as much yarn as 40,000,000—the whole present population of Great Britain—could with the one-thread wheels. A spinner produced as much in a day as he produced in a year in the last century; one man and one boy print as many goods as a hundred men and a hundred boys could have printed formerly." Notwithstanding the enormous advantage which the wonderful invention above alluded to gave England, the manufacturers sought, and obtained, protection against foreign competition, which protection lasted until other advantages more than compensated for its abolition to their advantage. And so, if we follow the history of your customs' tariff down to the final repeal of the Corn Laws, 1846-49, we will find that even the passage of this Act of repeal, which was heralded abroad as a great triumph of principle by Cobden and his followers, was not entirely due to the faith of the majority who voted for it in the economic theory which was preached as a new gospel for suffering humanity. Confirming the above statement the never failing Gibbins says:—"It is curious to note how the Factory Acts were passed in the first instance; these Acts all showed the steady advance of the principle of State interference with labour; a doctrine not distasteful to the old Ricardian school of economists, even when that interference was made in the interests of the physical and moral well being not only of the industrial classes, but of the community at large. Hence the economists aided the manufacturers of the day in opposing the Acts to the utmost of their power, and the laws passed were due to the action of the Tories and the landowners, but the millowners had their revenge afterward when they helped to repeal the Corn Laws in spite of the protest of the landlords who did not mind the workmen having shorter hours at other people's expense, but objected to their having cheaper bread at their own."

So many and so severe have been the criticisms upon the tariff legislation of the United States—termed hostile to England by some of its critics—both in your newspapers and in some instances in the correspondence of English manufacturers who have been invited to be exhibitors at Chicago in 1893, that it seemed necessary to me, at the risk of wearying you to hold up before you the reverse side of the picture, England's free trade policy as viewed by us in the United States, with some of the facts in history upon which that view is founded. Once more I say without expressing any opinion myself upon the right or wrong or expediency of either policy.

Whenever and wherever in England the coming Exposition has been discussed, whether in the drawing-room or the counting-house; in the correspondence of your Secretary with those who are in position to best represent Great Britain and Ireland, the McKinley tariff has been brought forward as an impassable obstacle, and as a piece of political legislation absolutely without precedent, and hostility to England has been proclaimed by many as the motive behind it, but the absurdity of this view is now seen by the intelligent observer of events who has a knowledge of your own commercial history. Self-interest is the motive for such legislation; and when intelligently and properly directed, a worthy motive, which enters into every action of individuals and nations, never absent in the case of the latter. During all of the period, the history of which I have hastily, and, as briefly as possible, reviewed, down to and including the passage of the Corn Laws, this was the controlling motive of your Parliament at Westminster, and it is national self-interest, as understood by its members, which govern the Congress of the United States at Washington. As to the wisdom or right displayed in any act at either place I have expressed no opinion, I would have failed in my duty to you, and to the interests which I represent, had I left unnoticed on this occasion the criticisms, private and public, which have been freely expressed of our recent tariff legislation, and the way I have treated the subject was the only one open to me. Probably I would not have given this part of my paper so much space, or devoted so much time to laying the above facts before you, had your Secretary not asked me to read a paper on the McKinley tariff, which he recognised himself, on a word from me, as hardly appropriate for me in my official position.

PART II.—FUTURE TRADE RELATIONS.

We can now pass on to the more practical part of my subject—especially practical at this time, as it involves the question which your manufacturers and merchants have to decide without further delay—"How large and how representative shall the exhibits of British and Irish industry be at the forthcoming Columbian Exposition?" The British Colonies, while slow at first, are now putting forth every effort to

secure such a representation of their products, natural and manufactured as has never been made before. I therefore leave them out in formulating the above query.

The future trade relations between Great Britain and the United States is the subject with which I have directly to deal. Considering the present trade relations, notwithstanding our new Customs' tariff, it is a matter of constant surprise to me that your manufacturers, without regard to their being directly, and in that sense personally, interested in the trade with the United States on account of exporting their own products thither, have not vied with each other, not only in themselves becoming exhibitors, but in co-operating in every way with your Council, appointed the Royal Commission, to take care of the interests of Great Britain and Ireland at the forthcoming Exposition. It is to the interest of every one of your manufacturers, even those who export no part of their product to the United States, that no question be left in the mind of the visitor at Chicago in 1893—whether he come from one of your own colonies or from South America; from Canada on the North to Cape Horn on the South; from India, from tradition in the East, to Australia in the West; that no question be left in the mind of the visitor at Chicago in 1893, as above said, as to the place which you hold and have held so long in the commercial world, which place will be indicated to thousands of those visitors by the comparison which they will make between the British section and the German, or the French, or the American section, and by American I mean the United States. From all over the world will come the shrewdest merchants of every nation, not for pleasure only, but also, yes mainly, to see whether or not they can purchase in the United States or Germany perchance, the articles which they do not produce themselves, to better advantage than from countries which have hitherto benefited by their patronage, England prominently.

Before entering upon the discussion of my subject, I must first repeat the statement which I made from this platform on the evening of December the 11th last; that the United States is by far your best customer, and here give you the list of your twelve best customers placed before you on that occasion. So far is the United States in the lead, that in racing parlance, appropriate not only to this country, but also to this occasion for reasons which will be clear to you, there is not a good second in the field; for the United States buys from you fifty per cent. more than Germany, your second best customer. Here is the list, which some of you will doubtless remember:—

COMPARATIVE STATEMENT OF THE EXPORTS OF GREAT BRITAIN AND IRELAND FOR THE YEARS 1890 AND 1891, TO THE COUNTRIES WHICH RANK AS HER TWELVE BEST CUSTOMERS.

Countries to which Exported.	1890.	1891.	Increase.	Decrease.
	£	£	£	£
United States	32,068,128	27,544,720	..	4,523,408

Total	£137,473,157	£126,270,141	£1,023,856	£12,226,872

I append the Table for examination at your leisure. Coupled with other similar statements with which I will furnish you, it may lead some of your manufacturers now hesitating about being exhibitors at Chicago in 1893, to lose no more time in making a worthy display in order that they may have a "place"—again resorting to racing parlance—in the contest which will be concentrated, for the time being, at the World's Columbian Exposition. In measuring the benefits derived from exports, you — and especially the British

manufacturer who has no direct interest in the exports to the United States—must bring yourselves to appreciate the fact that in whatever proportion the United States is a customer for any given article, they help in like proportion to support the industries which find no market in the United States, but are dependent upon the cotton manufacturer, for example, who does; the engineers and machinery builders; the owners of your coal mines and the miners who work them; your railway companies, which transport the raw material and the finished product to and from the mill; your steamship companies, which have a monopoly, aided by our tariff, in the transportation of raw material from and purchased product to the United States; and even your landowners.

To show over what a wide range of industries your exports to the United States are spread—ramifying in their benefits through other industries as above indicated—and how distributed between the manufacturing centres of Great Britain and Ireland, I here insert a list of 105 principal articles with which you supply us, and the names of the places from which they are shipped. (See pp. 533-4.)

These go in varying quantities from Belfast, Birmingham, Bradford, Bristol, Cardiff, Cork, Dublin, Dundee, Dunfermline, Falmouth, Glasgow, Huddersfield, Hull, Leeds, Leith, Liverpool, London, Manchester, Newcastle, Nottingham, Plymouth, Sheffield, Southampton, and Tunstall.

This list develops the fact that the manufacturers who have the largest share in the trade with the country which is your best customer, are the ones who have complained the most bitterly about our recent tariff legislation. On the real effect of this legislation I will have something to say later on, as it, of course, bears upon the question we are dealing with. Owing to my having been called on to read this paper now instead of a fortnight later, the returns for 1891 are not accessible, and, therefore, the list is for the last quarter of 1891. I see from this list that drugs and chemicals are the largest in amount. Woollen and worsted goods, with the addition of stuff goods, which are a mixture of woollen, take second place with a total of approximately £700,000, with an increase over 1890 of about £125,000; next comes tin plates, and after this linens, with cotton following close behind; after that iron and steel manufactures, and then glass, china, and earthenware, of which I am glad to know that a firm well known to you all, and bearing a name with which the rolls of this Society are honoured and known in America as well as England, is going to make a splendid exhibit at Chicago, in 1893. I must read to you here the increase and decrease in the twelve articles largest in amount on the above list of exports, and then pass on to the point they naturally bring me to—the effect of our present tariff upon the present trade relations of the United Kingdom and the United States. (See Table, p. 535.)

Looking over the above list, and seeing that at or near the top are the manufacturers who have grumbled the most about our new tariff, I am reminded of what an Irish or an English friend—perhaps your Secretary—I hope he will not shirk it if I say it was he—at least in so far as it pertains to Englishmen—told me, as a proverb all over the United Kingdom, "That an Irishman was never at peace except when he was in a fight; an Englishman never happy except when he was grumbling; and a Scotchman never at home except when he was abroad." I mention the Irishman and the Scotchman, with both of which I am allied by blood, as I do not wish to slight my own kinsmen. It must be concluded, then, that your cotton and woollen manufacturers are happy, and they have reason to be, as have all of your manufacturers, at the results so far of the McKinley Tariff. Let us see what these results have been, and how far and in what direction the variations in your trade are due to the tariff. To do this we must first compare the exports of the United Kingdom to the United States for last year with 1890, on October 6th, of which year the new tariff went into effect—being in effect practically for the last quarter of that year.

Then, or secondly, we must examine into other causes which were actively at work to bring about a shrinkage in your trade, not only with the United States, but with every part of the world, before the tariff went into effect, and entirely independent of it, and culminating after.

Next, or in the third place, we must examine into the conditions of trade generally preceding the great Baring failure, and ask in how far these conditions would have operated to prevent any increase in 1890 over 1889, if they did not actually work a decrease, without the stimulus of profit growing out of the advance in prices resulting from the tariff.

In the fourth place, we must compare the

VALUES OF PRINCIPAL ARTICLES OF EXPORT FROM THE UNITED KINGDOM TO THE UNITED STATES FOR THE QUARTER ENDED DECEMBER 31ST, 1891.

decrease in your exports to the United States with the corresponding decrease to other nations of such rank in commercial importance in their relations with you as to be worthy of special mention.

In the fifth place we must ask what natural causes are at work, aside from the tariff, which may be called artificial, to check for a time, if temporary, your exports to the United States, or if permanent, to ultimately bring about a steady decrease in them, or in some of them, to be replaced perhaps by something else. And then you must ask yourselves how far disagreement between labour and capital has operated, and will operate to further complicate the question, and then if you will allow me to add to the puzzle, one query for your textile manufacturers of Manchester and Bradford especially, how much of the loss in their trade is due to change in styles, fickle as the wind, which they themselves are moving too much in a groove to anticipate. Upon the two last I will have nothing to say.

I find support for the line I have chosen in the above questions, and the causes for declining trade, which many of your manufacturers at least haver efused to consider, in a daily paper of recognised standing. "During the last few years," says the *St. James's Gazette* of the 1st instant, "the country has passed through a serious crisis. The contraction of trade, due in a large measure to over production and over speculation, the collapse of two great financial houses, the hostile tariffs" — note the characterisation "hostile"—in America and elsewhere, and the labour troubles have had "far less effect than could have been anticipated," the reason given being of a character with which we have nothing to do.

Now for our questions *seriatim*.

The exports from the United Kingdom to the United States in 1890, as shown by the tabular statement above given, amounted in value to £32,068,128 out of a total of exports of £176,160,202, the United States taking 18 1-5th per cent. of the total, while in 1891 your exports to the United States amounted to the value of £27,544,720 out of a total of £161,305,487, the United States taking 17 per cent. of the total; a loss of one and one-fifth (1 1-5th) per cent. But an artificial stimulant had been administered in 1890 in the shape of the tariff proclaimed as coming, and inducing heavy buying in anticipation thereof. In the first quarter of 1890, as compared with 1889, there had been a falling off

in the exports to the United States to the amount of £566,302, followed by a reaction which, considering other concurrent incidents, could not have been expected without the stimulant above alluded to. Under its powerful influence the second and third quarters of 1890 showed an increase over 1889 of £2,600,801. The whole of this increase is considered by those in the most favourable position to judge of the causes which produced it, to be due to purchases made in anticipation of the advance in prices growing out of the new tariff. The whole amount of this increase, to properly compare the two years therefore, should be deducted from the total of 1890 and added to that of 1891, the result of which would be that your exports in the former year (1890) would show a total of £29,467,327, and of the latter (1891) a total of £30,145,621, providing that other concurrent events above alluded to had not intervened to check your trade with us, and had our merchants purchased as freely in the ordinary course of trade without the stimulus of speculative profit.

But the trade of 1891 also was helped by the artificial stimulant of the increased duty on tin plates taking effect on July 1st of that year, your exports of that article showing an increase for the year 1891 over the year 1890 of £480,000, notwithstanding the heavy decrease in the last half of the former year, as indicated by the figures for the last quarter, given above. Leaving tin plates out of our calculation, your exports to the United States for the last quarter of 1891 show an increase of approximately £470,000, some of the items of which increase I have given above. It will be time enough to deal with the actual and permanent result of the tariff when we are far enough away from the passage of the Tariff Act to judge of it. What the owners of your tin mines have most to fear is our finding tin in the United States in such quantities, and of such quality, as to enable us to dispense entirely with the duty. Quoting from an article by Mr. Andrew Carnegie, in the *Nineteenth Century*, for June of last year, "It may now be noted that prices in Europe and the United States, for everything, draw nearer and nearer together. In recent times, steel rails, for instance, have sometimes been quite as cheap in New York as in London, and very often as as cheap as foreign rails could have been imported to New York free of duty."

There is a clause in the McKinley Tariff Bill, of which I have heard no complaint, but which has a more important bearing upon your manufacturing interests than its protective features, it reads:—"That where imported materials on which duties have been paid are used in the manufacture of articles manufactured or produced in the United States, there shall be allowed on the exportation of such articles a drawback, equal in amount to the duties paid on the materials used, less one per centum of such duties."

As for the second question, the causes other than the tariff which operated to bring about and intensify the shrinkage in your foreign trade generally, these are too recent, and their effect too deep and widespread in this community to require more than passing notice from me. These causes other than the tariff —"over-production, over-speculation, the collapse of two great financial houses," with possible results so serious as to justify the Bank of England stepping in and borrowing large sums abroad, to arrest a disaster from which you could not have recovered for years, with the most profitable trade at home and abroad. In what relation did the United States stand to you at this juncture? First of all, just prior to this crisis, she increased enormously her purchases from your manufacturers, enabling them to reduce their discounts with their bankers when money was worth a premium. Following these increased purchases, they bought back securities to an amount far larger than the loan sought for and made by the Bank of England from the Bank of France, thus rendering a service even to the manufacturers, who must depend largely upon the banks, more than off-setting in advantage the whole decrease in your exports to the United States for the last quarter of 1890, had this loss of trade been an actual and permanent loss instead of no loss at all, but only a transfer of the transaction to an earlier period of the year.

I have already anticipated my third heading, and will now only note it to point out to you the beginning of the shrinkage in your trade. The collapse in Argentine as first indicated in a decline in your exports to that Republic, from the high-water mark of 1889—£10,681,879 to £8,416,112 in 1890, and then to £4,240,602 in 1891—to say nothing about the losses there from "over-trading and speculation." Fair crops in 1890, and large crops in 1891 in the United States, and an unprecedented demand for our breadstuffs during the last quarter of 1891, making business of all kinds good with us, and enhancing our purchasing power, was the balance

wheel which saved the world from a financial disaster, such as history hardly records. What the conditions were in the financial capitals of other countries is well known to all of you. They had all the securities they could stagger under.

We now come to our fifth question, What natural causes are at work, aside from the tariff, which may be called artificial, to check your exports to the United States, and in time, if permanent, bring about a steady decrease in them or some of them, to be replaced perhaps by something else ? and I will add here, What are the natural impediments in the way of these natural causes, which may tend to defer for years to come their full fruition without some aid; as the mountain deflects from its straight course, the mighty river, which in time cuts its way through solid rock, unaided by dynamite, or blasting, or other modern inventions, artificial, as is the tariff, but still when applied with proper limitations as to time and place, circumstance and quantity, only brings about, though hastening, results in accordance with natural laws. As to the first part of this question, there are several causes at work, aside from the tariff, not only to cut off your exports, especially of cotton goods to the United States, which are only one and fifteen one hundredths of one per cent. of your total export of cotton goods, but also to bring the United States to the fore as a competitor in this line of manufacture in your other foreign markets, prominently in South America, China, and Japan. It is no more in accordance with natural laws for you to bring the cotton from the United States, and send the manufactured article to countries in closer proximity than you yourself to the cotton fields, than it was for you in the 16th century to send your wool to Flanders to be manufactured and distributed from there to the consumer. The place for the cotton mill is in or adjoining the cotton field, and there the next generation at the latest will find it in its most prosperous condition. Until about the year 1890, after the period of reconstruction following the "late unpleasantness" as we now call the late war, the South was purely agricultural, with no ambition to be anything else. It was only a question whether their cotton would be sent to New England or Old England, and Baines, in his History of the Cotton Manufactures, tells us that the difference between the freight on cotton from New Orleans to Boston and New Orleans to Liverpool, was a quarter of a penny per lb. But as the discovery of coal and iron in the north of England (in Lancashire) resulted in your cotton mills and other manufactures locating there, so the discovery of iron and coal in Alabama opens the way for the construction and operation of mills to as great advantage in or adjacent to the cotton fields. The new south is to the United States what the west was fifty years ago—the place for men with brains, experience, and capital—such as some of your cotton manufacturers at Manchester and Bradford. Twenty-five years ago, any railroad manager of prominence, or anyone versed in railroad affairs, would have told you there was no money in lines running north and south, that only lines connecting the east with the west could pay. But now the west, rich herself, is reaching out southward as is the east, and capital is flowing into the southern States for the development of her industries. So large and so important have become the agricultural and industrial interests of our Pacific coast, and the traffic between it and the Atlantic coast, that with the capital for such works, we have not only been brought to the recognition of the importance of a waterway for ocean steamships between the two, but a company has been organised for the construction of a ship canal across the Isthmus of Nicaragua. But the results of the construction of this canal will reach beyond the boundaries of the North American continent; shifting some of the existing avenues of commerce thousands of miles. "The discovery of the passage by the Cape of Good Hope destroyed the overland trade with the East, and overthrew the commercial supremacy of the Mediterranean cities. The Suez Canal in like manner so superseded the passage by the Cape of Good Hope, that the discovery by the Portuguese has become nearly as sterile as that of the Carthagians told of by Herodotus. It is the medium of commercial intercourse between Europe and Western and Southern Asia." How will the opening of the Nicaragua Canal affect the present channels of trade and the present trade relations, especially the trade relations between Great Britain and the United States? How will it alter the relative distances between New York, on the one hand, and Liverpool, on the other, from the markets of the Pacific coast of both North and South America, and the ports of China and Japan, and India and Australia? "New York and Liverpool by 'The Horn' are equally distant from San Francisco, viz., 15,600 miles, and the same is true of all other ports on the Pacific coast," says the Hon. Warner Miller, Presi-

dent of the Nicaraguan Canal Company, in an article in the *Forum* for February. "By the canal, New York will be distant from San Francisco 4,900 miles, whilst Liverpool will be distant from San Francisco 7,600, or a difference in favour of New York of 2,700 miles; and this difference in favour of New York over Liverpool holds good as to all the ports on the Pacific coast of both North and South America. To-day Europe controls more than three-fourths of all the trade on the Pacific coast of both North and South America. With the canal constructed, giving the merchants of the Atlantic coast 2,700 miles of advantage over Europe, they will be able to secure the bulk of that valuable commerce. At the present time there are more than 70,000,000 people on the islands in and continents bordering on the Pacific Ocean, who will be brought nearer to New York by distances varying from 3,000 to 10,000 miles, and, taking no account of the vast population of China and India," all markets now under the control of the British manufacturer. "Shanghai is 300 miles nearer New York by the Nicaragua Canal than Liverpool by the Suez, and New York 2,000 miles nearer Yokohama than Liverpool by the Suez, thus giving New York an advantage over Liverpool in competing for the trade of Japan. Melbourne in Australia, and Auckland in New Zealand, are brought 4,000 miles nearer New York by the canal than by 'The Horn.'"

Bombay and Calcutta, the ports of your great Empire in India, are 7,000 or 8,000 miles from Liverpool by the Suez Canal, and to-day you are drawing large quantities of wheat from India over a line which is 8,000 miles shorter than the distance round the "Horn" from Liverpool to San Francisco. With the completion of the Nicaragua Canal this difference is wiped out. From ports in the Gulf of Mexico —New Orleans, Mobile and Galviston—the distance is only 1,200 miles from the western mouth of the canal, which is 800 miles less than the distance from New York. This will open a market for the raw cotton of the South in Japan where 40,000,000 of people use cotton as their chief article of clothing. With the distance from the Gulf of Mexico to Japan reduced over half, we could supply the Japanese market in competition with India; and furthermore supply India herself with the longer fibred product of our own cotton fields, for mixture with her own, the "shortness" of the fibre of which is a great difficulty in the way of the Indian manufacturer competing even on his own ground with his English rivals.

When I made my first allusion to the establishment of cotton mills in the centre of or adjacent to the cotton fields in the South, and from it passed on to the effect on this trade and the trade of the United States generally with the west coast of both Americas, of the opening of the Nicaragua Canal, and what is to us the still farther west, China, Japan, and India, it was not with the intention of taking this staple, and presenting it as an illustration or example of our future trade relations. But I see no better method than this, and I shall therefore follow it. And it is peculiarly fitting that we should take the movement of cotton, a raw material, as indicative in its present and future phases of the present and future trade relations of Great Britain and the United States as I see them, and follow it through the finished product to the back of the wearer of the coat made from it, for it is typical of our exports to the United Kingdom, as it is typical of your exports to the rest of the world. More than this, it heads the list of your manufactures in value, its value being double that of your woollen manufactures, and as much as your woollen and steel and iron manufactures, including machinery and steam-engines combined, and about 22½ per cent. of your total manufactures. The value of your cotton manufactures in 1840 was £24,678,460, while in 1889 the latest figures I happen to have at hand was £62,089,442; and for this output the United States furnished you with about eighty per cent. of your raw material, the product of which you send all over the world.

Your imports from the United States are in fact raw materials without exception—breadstuff and meat products being the raw materials of, or at least sustaining brain and brawn; directly in the latter case, indirectly in the former as the fuel, the combustion of which generates the heat which runs the dynamo of the brain. Here is a list of the principal articles we sent you in 1890, in the order of their respective values:—

	£
Raw Cotton	36,571,848
Breadstuffs	19,890,486
Bacon and Hams	7,474,737
Oxen and Bulls	7,351,981
Fresh Beef	3,629,919
Tobacco	2,530,510
Cheese	2,081,546
Lard	2,049,747
Leather	2,019,359
Petroleum	1,719,654
Oil Cake	1,355,853
Total	£86,675,640

Not only are raw materials by far the largest part of our exports to Great Britain, but also of our total exports, forming 82 per cent. of that total for our fiscal year, ending June 30th, 1891; 50·62 per cent. of which total I may add you took from us, sending us 23·05 per cent. of your total exports during the same period.

The future trade relations between Great Britain and the United States will depend upon the latter's ability to convert her raw materials, which she now exports, into finished product, and sell the latter in foreign markets which you have hitherto controlled. What we expect the Nicaragua Canal to do in this direction in certain markets—the western coast of both Americas, and the farther west to us, China and Japan—I have told you above. The British manufacturer has heretofore had the advantage of cheaper coal than his competitor in the United States, but this advantage seems to have disappeared.

The average price of coal in Great Britain during the year 1889, I have seen it stated, was 6s. 6½d., or about $1·57 in American money, per gross ton of 2,240 pounds. In his recent report, the Commissioner of Labour of the United States gives 98½ cents per net ton, or $1·10 per gross ton, as the total cost of producing lump coal at ninety-nine mines in the United States; and it is stated that for two years past the best Virginia coal has been sold at tidewater at a less price than English coal is sold at Newcastle. So it would seem that England has already reached the phase when her manufacturers have not the advantage of cheap coal as compared with their competitors in the United States; and the difficulty must increase, as has recently been prognosticated by more than one writer on this economic subject. Notwithstanding the facts I have laid before you, many of you will say, in hunting parlance—appropriate to the occasion as is racing parlance—that I am "riding before the hounds," and that this generation of British manufacturers need not concern itself with anything so remote as the competition in a field foreign to both, of a country 82 per cent. of whose exports are materials raw, or having their value but slightly increased by change of form. This I will grant you, with the limitation of the near future; for already we have entered the export field; and notwithstanding the depression felt all over the world following the Baring catastrophe, for such it was, and to you especially, and the shrinkage in your own trade, the exports of manufactured articles from the United States increased 7·3 per cent. In the article of locomotives there is an increase of three for one in value, rising from $1,037,404 (equivalent to £207,481) in 1890, to $3,274,825 in 1891 (equivalent to £654,965). These locomotives have been distributed as follows:—To Cuba, $958,084 (£191,617); to Brazil, $1,837,796 (£367,557); and to your Australasian colonies, $892,295 (£178,459). There was also a gain of $1,257,151 (£251,437) on a total, in 1890, of $4,019,714 (£803,945) in road and rail cars; of £10,000 in sewing machines, nearly £17,000 in glass ware, £9,000 in locks, hinges, and builders' hardware, £14,000 in saws and tools, £15,400 in stationary engines and boilers, and £166,500 in machinery not specified. Are your engineers and machinery manufacturers going to make a display at Chicago that will check this increase, or will they (your machinery manufacturers) leave the mutually foreign field, which can be so advantageously worked at Chicago, for the American manufacturer to diligently till without contest on that important occasion, while they rest contentedly on their past achievements?

Our exports of raw cotton amount in value to about £58,000,000, while our exports of manufactured cotton only amount to about £2,721,000. These figures, as time goes on, must come together, if not reverse themselves through the operation of the agencies I have named above, and you must divide with us, at least, the trade in cotton manufactures foreign to both. With the completion of the Nicaragua Canal, the Australian wool, which now comes first to London, and is then re-exported to the United States, will come direct to our Atlantic ports, cheapening it to the American manufacturer. To-day woollen manufactures do not figure in our exports, and are not likely to be for some time; but we are large buyers of woollen goods from you, having taken about $700,000 worth of the product of your woollen mills during the last quarter of 1891, with an increase, as shown above, over the corresponding period of 1890. During the last-named year, we bought woollen goods from you to the amount of about £5,300,000. I also note in the annual statement of the trade of the United Kingdom, under the heading of "United States" exports thereto of foreign and colonial manufactures for each of the five years beginning 1886-1890, that you sent us foreign and colonial woollen manufactures valued as follows:—1886, £52,277; 1887, £123,186; 1888, £203,632; 1889, £353,642;

1890, £1,033,939. How far this enormous increase has been of a character to displace your own product I do not know, but it is a question for you to ask yourselves whether your foreign and colonial competitors are, through the aid of English merchants, cutting into your woollen trade. At present there seems no likelihood of our becoming competitors with you in woollen manufactures in markets mutually foreign, though the total of our output is three times the value of yours, the former being £66,000,000, and the latter about £20,418,482, for the year 1890.

Our iron and steel industry has overtaken and passed yours in magnitude. In 1890, our production of pig iron was 9,202,703 tons, against 7,875,703 tons in the United Kingdom; and our production of Bessemer steel, 4,031,535 tons, against 2,014,843 tons from your furnaces. Of manufacturing iron, including rails, 2,820,377 tons were produced in the United States, against 1,923,221 tons in Great Britain.

Time does not suffice for me to enter further into particulars, or to more than allude to your other industries, especially the one which has been at once the mainstay of all the others, and dependent upon their support—your shipping. I read, I think in the *Daily Telegraph*, some time last summer—at least, during the Naval Exhibition: — "Throughout all the generations we have been a people delighting to go down to the sea in ships, and prone to protect our countless fleet of merchant ships which we have sent to carry our commodities to the uttermost ends of the earth, by ships of war armed to the teeth, manned by sailors prepared to go anywhere, and ready to do anything, and commanded by officers in whose dictionary the word fear was not to be found."

I hope, as I know you do, that your navy and ours—which we are building—may never come together in battle except as allies; but with your merchant shipping we will soon be in a position to take the field as competitors in the trade of which, as above said, you have had a monopoly ever since the iron steamer displaced the clipper ship, with which we had well-nigh grasped the palm. To-day, the products of your looms and workshops which you send to us, and the bread-stuffs and raw materials with which we supply you, are carried to and fro in British bottoms, as well as the enormous number of my countrymen who visit England every year, to add not only to the revenues of your steamship lines, but also in an enormous degree to the profit of the London hotels, lodging-house and shop-keepers, and manufacturers. The tonnage of vessels entering and clearing from British ports for the United States during the year 1890, was 9,329,720 tons, of which 8,219,872 tons were British bottoms, and 259,965 were American, and this wide difference we propose to make beautifully less. "The Germans, too, who have but lately entered this field," says an English newspaper, "once all our own, are not only challenging, but beating us hand over hand. Two of their lines (the North German Lloyd and the Hamburg American) actually carried more passengers to New York than all our Liverpool vessels put together. Furthermore, they beat the swiftest of our lines in carrying the mails by no less than nine hours and fifty-seven minutes." And they are doing this at a profit.

In your future trade with the United States, whether it be as a customer, or a competitor, much will depend upon the readiness and celerity which your manufacturers manifest in the adoption of improved machinery, and in adapting themselves to the changing methods of doing business, and their output to the changing tastes and requirements of those upon whose patronage they depend—that is changes in fashion. To the lack of these—absolute requisites no matter at what cost, to success in this day and generation—is to be attributed in large part the dulness in trade of which your manufacturers are now complaining, attributing all to the McKinley Tariff. In support of this view, I will quote from a very interesting article which appeared in the *Leeds Mercury* of January 5th. Referring to "the great firms of Manchester merchant princes," says the *Mercury* going back, of yesterday, "If we look back forty years, we shall see that a great destructive work has been in operation among them, and the hand of death has obliterated many of the best known names. One of the forces which have been working against them is the tremendous change in the style of business consequent upon the development of railways and perfection of machinery, the rapid turning over of stocks, &c.; and those only have survived the new order of things that have had the foresight and energy to adapt themselves to the existing changes. As a matter of fact, the names of the large firms who have foreseen and met these changes can be counted upon the fingers of one hand. A similar weeding out process has been going on in the manufacturing trade. Take

the case of Bradford. Never perhaps has that enterprising town passed through a more sifting time than during the past few years, when a complete change of fashion, from the bright haired wools—which the Bradford manufacturer could manipulate at will—to the softer and rougher Cheviots, has been so marked. Those who have adapted their looms to the popular demand have survived, while many who have clung to the hope of a return of fashion to the lustre goods have been compelled to retire; if, indeed, they have not lost their all. In the manufacture of plain Bradford goods also, such as cashmeres, the stern law of the survival of the fittest has been very apparent, for the race has been against time, and the man of capital who could put down the newest and fastest machinery has done the trade to the exclusion, and ultimate extinction, of his poorer rival. This feature is very noticeable in the Huddersfield trade, where during the last twelve months some twenty small manufacturers have 'gone to the wall,' crowded out by firms with larger capital, who have put down machinery of the most modern construction, with running powers from 25 per cent. to 50 per cent. in excess of the old machines of twenty years ago."

It is the law of the survival of the fittest in the competition which your own merchants and manufacturers make among themselves. If your own manufacturers read your own newspapers, and gave serious thought to what they contain, including the changes recorded in them as taking place in other parts of the world, they would find great profit from so doing. The merchants and manufacturers in the United States are more alive to what is going on in the rest of the world, even to having samples sent him, from every manufacturing centre, of anything new which is produced, that he may buy it or copy it (if this is done) as the circumstances of the case make most profitable. So that your manufacturer who would remain away from the Chicago Exposition lest his exhibit be copied—as suggested by a member of the Liverpool Chamber of Commerce, as a reason for not co-operating with your Council—would only lose the benefit of showing his wares, while the American manufacturer would be exhibiting the reproduction of the very article which his less enterprising competitor had thought to keep from his envious and rapacious hand, if he were disposed to copy patterns, as has been freely stated; at the same time telling the visitor at his stall in the American Section, to whom Great Britain and the United States are both open as a source of supply, " If you wish anything different, no matter how divergent from our present output, describe it, and we will submit patterns until you say you are satisfied, and produce for you just what you want."

Nothing that I have said before about our becoming in time competitors with you in supplying the rest of the world with manufactured articles - especially cotton—bears in the immediate future upon our present relations of interchanging raw materials for finished product. For while our resources are such as to point to our becoming in time such competitors, we have too much else to do in the way of what might be called "opening up the country" to enter for the present vigorously upon that career which will be ours in due time. We are like the vanguard of a great army advancing into, and taking possession of, an unknown and uncultivated country, rich as the Promised Land in everything that can contribute to the wants of man, but requiring first that forests be cleared, houses built, crops planted, and allowance made for the harvest to follow, seed time according to the laws of nature, and hence requiring to be largely provisioned from a base of supplies such as you have been to us from the time the first colony landed upon the shores of Virginia, and barely kept soul and body together by begging corn from the rude savage found in possession of the land. For many years to come we will have to send you our corn now produced beyond our own requirements, the productions of which we have well nigh brought to its maximum, while in other things we are but upon the margin of our resources and capabilities. As your great enterprises—your manufactures and your shipping trade had small beginning, and grew year by year, correcting mistakes of inexperience, improving methods, cheapening the art of production, so must ours go through the several stages of imperfection until time, as it matures the boy into the man, brings them to their full stature. I must refer in the little time that is left to one other factor of no less importance in the trade relations of the future between Great Britain and the United States, and that is to our purchasing power, which is increasing by leaps and bounds, and the cultivation of the tastes of our people, increasing their wants in proportion to the ability to gratify them. I can see no better way to carry an idea of this point to your minds than by giving you a few statistics as to our internal com-

merce. The traffic upon our great lakes compared with your traffic on the sea, will give you a fair idea of the magnitude of this internal commerce. The tonnage of vessels entering and clearing at the port of Chicago, in 1890, was 8,774,096, while the tonnage of ships entering and clearing from the port of Liverpool was 9,329,720 tons. The tonnage of vessels that passed through the Detroit River was 21,288,472 tons, and that through the Sault St. Marie Canal 9,041,213, as compared with a tonnage of 6,723,187 tons through the Suez Canal. The tonnage at the port of Chicago doubled itself in the last census decade, and it is not unlikely that 1900 will show an increase in like ratio over 1890, for 53,411 miles of railway terminal at that port, and in a year move 43,000,000 tons of freight. In the central, northern, and north-western States,, the total freight moved was 196,000,000 tons; and this is without mentioning the traffic on 20,000 miles of navigable rivers in the United States. "In these great channels, the domestic exchanges represent an annual value, perhaps, twenty-five times as great as the total of exports and imports," Mr. Blaine, our Secretary of State, tells us in his work "Twenty Years in Congress." The River and Harbour Bill of the present Congress appropriates $21,000,000 for river and harbour improvements, $4,000,000 which is to be expended upon the Mississippi River between its mouth and St. Paul, and authorises the Secretary of War to make contracts for $12,000,000 more to be spent on the same work, to be expended in sums of $4,000,000 a year. Besides those expenditures, provision is made in another Bill for improvements in the harbour of Galveston, Texas. It is to the water-ways that we owe the cheap transportation which has contributed so much to our marvellous development. It is interesting to compare the present cost of transportation to that of seventy-five years ago. In 1817, it cost $140 to transport a ton of freight from Philadelphia to Pittsburgh, while in 1886, at the average rate received by the Pennsylvania Railroad for the carriage of freight, three-quarters of a cent per ton per mile, it cost $2·87. At the former time, the working man in Philadelphia had to pay $14 for moving a barrel of flour from Pittsburgh, against 28¢ now, and the Pittsburgh consumer paid $7 freight upon every 100 pounds of dry goods brought from Philadelphia, which 100 pounds is now hauled for 14¢. From this you can get some idea of the work to which I referred above as "opening up the country."

Behind this work we have an army of 65,000,000 people, honest, industrious, facile of brain and expert of hand, bold to plan and ingenious to execute, and it is not difficult to forecast the future of the United States in the ordinary course of events. But there is still room for men of the character who laid the foundation of our greatness, and who have contributed to its upbuilding. If changing conditions point to the United States as the place offering the best return not only for your capital which you have already largely invested there, but also for your ingenuity and labour, you will find a welcome for yourself as well as a place to invest your money with profit.

I have endeavoured, gentlemen, to lay before you as briefly as possible a *resumé* of your own commercial policy and the view taken of it by other nations, in order that, seeing the question from our standpoint, you might judge us fairly in the policy we are pursuing. I hope I have met with some success in this particular.

In the second part of my address I have endeavoured, in reviewing the present condition of trade between Great Britain and Ireland and the United States, to place before you in a strong light, the other causes which, independent of the McKinley Tariff, were at work before the passage of this Act to cause a shrinkage in trade which was rather checked than accelerated by the tariff. After this I have endeavoured to point out the probable future course of trade between the two countries with the causes, which, as I see them, will operate in the direction I indicate, and then I have shown, or endeavoured to show, that notwithstanding these causes, at this present time operating in a very limited degree, for reasons which I have also indicated, the exports of Great Britain to the United States must continue to be large, increasing for a time at least from year to year, and as it reaches its maximum you must expect to find us running you close in the markets of the world, foreign to both, for we will then be powerful competitors in other fields. In order that the thin end of wedge, which I have pointed out to you is entering the field foreign to both, may not be driven in a marked degree further into the mass known as markets, when the merchants from these markets assemble at Chicago in 1893, does it not behove your manufacturers to be up and doing in the preparation of the great

exhibit which you have the material to assemble in solid phalanx in the British Section. This Columbian Exposition is absolutely unique in that never before has a country whose chief exports are raw materials which it exchanges for finished products, invited those who compete with her merchants to bring their wares for display and sale. You buy no manufactured articles from us and yon do not come as possible purchasers. Heretofore exhibitions, beginning with your own in 1851, have been held under widely different circumstances, the nations holding not only an exhibition in the modern sense, but also a "fair" in the ancient sense, whither merchants flocked to buy the goods displayed. But in our invitation to you there is even more than this. We have invited you as our kinsmen, a people in whose veins flows the same blood, and through whose institutions ramify the same laws and customs; a people who, worshipping God in their own way, which is our way, allow others the privilege of worshipping Him according to the dictates of their own conscience, as do we, or even to deny his existence, and not lose caste, if sincere and honest in such belief. Ignoring the creeds, we both stand for reaching out a helping hand to struggling humanity—the poor and the unfortunate, wherever found—and not only extending our trade over the known world, but with it the mantle of religion and justice. Linking these two great objects together, we can meet on the field at Chicago, in 1893 as rivals, not only in trade, but also in elevating and purifying its methods, and in extending the benefit of Christian civilisation to the uttermost parts of the earth. There is enough for both to do, and for both to reap in profit and honour.

May a laudable competition such as this be the only contest which time will bring in its flight between the two great English-speaking nations; and in this hope we may exclaim, in the words of the gentleman and scholar, poet, and diplomatist, your late Ambassador to Paris:—

"Then blow, blow the clarion and let the war roll,
Strike steel upon steel, and strike soul upon soul,
If in striking you kindle keen flashes and bright
From the manhood in man stricken thus into light."

And to give expression to, and emphasise the relationship which every thinking man must feel should exist between these two members of one family, in the part which it is for them to play in the future history of the world, perhaps we in the United States may look forward to the pleasure of welcoming your President, his Royal Highness the Prince of Wales, or some other member of your Royal Family, to represent your gracious Queen, who is respected with us, and all over the world, as she is beloved by her own people.

DISCUSSION.

The CHAIRMAN said they were much indebted to Mr. McCormick for pointing out so clearly the advantages which would be gained from exhibits at Chicago. He had had the advantage of visiting the United States several times, and must say that at the Philadelphia Exhibition the English were received with great cordiality, though even then the protectionist policy, which had now culminated in the McKinley tariff, was beginning. He felt quite certain that until the protective tariff had produced such an excellence in American manufactures as put them on a level with ourselves, it was an advantage to us, as it prevented American competition in foreign markets. No doubt the day would come when their industries would be developed, as Mr. McCormick said ours had been by protection, and then England would have to make great efforts to hold her own. It was of the highest importance to Great Britain that her manufacturers should be well represented at Chicago, which would be the finest Exhibition ever held, and would attract people from all parts of the world, and he hoped Englishmen would recognise this and exert themselves accordingly. He believed the Government had recognised the importance of our having a good representation there, and there was every hope of a large increase in the grant made to the Royal Commission, so that exhibitors would not be called upon to pay for the space they occupied.

Mr. DREDGE complimented Mr. McCormick on the admirable way in which he had acquitted himself of a somewhat difficult and delicate task. He had given an interesting chapter from the commercial history of England, and had let Englishmen see themselves as other nations saw them, which was a wholesome lesson if properly applied. Free trade views were so ingrained in us that we were apt to be intolerant of those countries which preferred to hug their chains, and live in the darkness of protection; but so long as England thought it was her interest to maintain protection, she pushed both the theory and practice to the extreme limit, and maintained it, moreover, on the highest moral grounds. When, however, free trade was found more profitable, it was discovered that there was a still higher commercial philosophy, and protection was denounced as something very wicked. We had no right to take up that intolerant attitude; but on the

other hand, we ought to be thankful that in spite of the McKinley tariff, which prevented millions of American citizens from enjoying the benefits which British manufacturers were ready to shower upon them, the United States were still such good customers, and we ought to do our best to maintain and extend that trade. Next year our foreign trade with South America, with the Colonies, with China and Japan, would be open to attack by all the manufacturing countries that exhibited at Chicago, and it was no use for us to pose as the greatest manufacturing country in the world, if we did not make our position recognised by other countries, and we should undoubtedly be judged by the display we made on that occasion. Some months ago he called attention in that room to the wonderful organisation which, under the name of the Latin American Federation, was being worked with much success at Washington, its object being to destroy, as far as possible, British trade with the republics of South America, and divert it to the United States. Probably some success might be achieved in the course of time, but we need not fear any very serious competition for some years to come in that quarter. There was, however, another peril much nearer home, and more imminent. Germany had as much reason as ourselves to be dissatisfied with the McKinley tariff, but they were not hanging back on that account from the Exposition; on the contrary, there was great enthusiasm over it, thousands were applyfor space, and the Government was making a grant of £100,000. This was not done on merely sentimental grounds; the intention was to make the German Section something to be remembered, a venture which should bear a rich harvest at our expense. No doubt the ultimate object was to share in the South American trade, but the immediate intention was to overshadow the British Section, and to obtain as much as possible of the £30,000,000 of trade which we did with the United States. And this result would undoubtedly happen unless our manufacturers showed more energy.

Sir H. TRUEMAN WOOD said he did not propose to follow Mr. McCormick into the large questions he had raised, but was glad to have the opportunity of saying a word on that part of the paper which dealt with the Chicago Exhibition, with which the Society was so closely associated. The Council had certain advantages over other Royal Commissions, and certain special drawbacks. Amongst its advantages was that of having amongst them Mr. McCormick as special delegate from the United States, a Chicago man, and thoroughly in touch with the executive of the Exhibition, who was always ready to give any information and advice. Amongst the drawbacks, he might refer to the fact that the matter had to a certain extent been drawn into the arena of politics, though this had not been altogether a disadvantage. Originally, the Council undertook to do the work of the Section with a sum of £25,000; and he held they would have done so with fair success, but the question got into Parliament; and there was a unanimous opinion in all quarters that the country was not being properly represented; that it ought not to be compared with Paraguay or Japan, but that the Commission representing Great Britain should have sufficient means to carry out its work properly. He believed, therefore, that the Government intended to throw a greater burden on the shoulders of the Royal Commission, and they would brace themselves to bear up under it. At all former Exhibitions, the Commission was left to do its best, and was then judged by the results; but, on this occasion, questions were asked in Parliament as to what was being done; and a statement had been made that the number of exhibitors would compare very unfavourably with those from other countries. Of course, the number of those willing to pay for space, and of those willing to ask for it, if they could get it for nothing, and could throw it up at any time, were very different. But he had reason to believe that, even if no further applications were made, the British Section at Chicago would very fairly represent most of the industries of the country. Some of the departments would be sadly lacking, no doubt. There would be a poor show of machinery, and very little in the way of agricultural implements; but that was foreseen from the beginning; and, in some other branches, we should be represented as well as could be wished. A trade was better represented by two or three first-class houses than by 20 or 30 small manufacturers. For example, at the Paris Exhibition, Belgium had about 120,000 square feet and 1,400 exhibitors; whilst Britain had about 200,000 square feet, and 670 exhibitors, which simply meant that they showed on a much larger scale than their Belgian friends. The great number of Belgian exhibitors was made up by collective or joint exhibitors. They were told that in the present case there were 2,500 coming from Germany, but if they were all to be packed into the space allotted to Germany, they would not make very much show in comparison with their number. It did not follow, because there were few British exhibitors, that it would be an insignificant show. There would be an excellent show, and if exhibitors were relieved of the charge for space, they would be able to apply the money in embellishing and setting off their exhibits. The two great hindrances were the McKinley tariff, on which he did not propose to say anything further, and the fear that productions would be copied; but when manufacturers sent first-rate work he did not think they need fear copying. There were certain branches in which we were ahead of America, as there were some in which she had the advantage; and in these matters, copy as much as they would, they would not produce the same thing, and the American customer would, as a rule, buy the genuine article and not the imitation. It was no use scolding the British manufacturer because he did not see fit to exhibit at Chicago; the proper way to go to work

was to show him, as had been done in the paper, that it was to his advantage, and then he would do it fast enough. A certain amount of patriotic feeling might be relied on, and one exhibitor, whom he saw present, was making one of the finest exhibits in a certain class, to a great extent from purely patriotic motives, but the interest of his firm was also involved. He had urged on the representative of one of the largest engineering firms in the world that such a firm should not look on the matter merely as an advertisement, but that it was their duty to represent British engineering. He said they were ready to do that, and did not mind spending two or three thousand pounds upon exhibiting, but they were not prepared to lose ten or fifteen, and that was, he held, the general feeling. A word in conclusion on collective exhibits. The French, Germans, and Belgians were willing to combine together to represent the industry in which they were engaged, knowing that the result would be to bring orders to the country, not necessarily to the particular firm exhibiting. It was worth consideration by manufacturers whether they would not do well to sink their trade rivalries, and combine together to represent English industry in any particular department. The attempt was being made in some instances, by the Institute of British Carriage Manufactnrers for example, mainly at the instance of Mr. Hooper, and he hoped other trades would follow the example.

Mr. ROBERT DUNCAN said the Chicago Exhibition had adopted a very ambitious title—The World's Fair—and, of course, claimed to represent the trade and industry of the world. Many British manufacturers felt that if they went to such an Exhibition, it should only be when a policy had been adopted worthy of such an ambition, a policy which looked not merely to the interests of the nation holding the Exhibition, but endeavoured to obtain fair-play for everyone. That could only be done by working harmoniously together, not by each nation trying to get the better of their neighbours. If the British people were thoroughly convinced that the United States were trying to get the better of them in the markets of South America, China and Japan, they would naturally resent it. A splendid move had been made in the direction of a policy of harmony, by calling a Conference of representatives of Chambers of Commerce from all parts of the Empire, to meet in London this year, and he hoped the same policy might be pursued in America.

Mr. STEPHEN BOURNE thought they were indebted to Mr. McCormick, not only for his candour in pointing out how we were seen by others, but also for throwing considerable light on the motives which had actuated the Americans in introducing the McKinley Tariff, and adopting what seemed to us a most retrograde policy, such as we were foolish enough to indulge in 200 years ago. It was not entirely foolish, however, and there was one argument to be adduced in favour of protection. When a country possessed natural advantages which were certain to make it successful in any particular branch of manufacture, it was perfectly justified in fostering that industry until it was able to run alone. We did that with regard to patents, giving protection for a time to a man, to enable him to do that which he believed he would be able to to do ultimately without any protection at all. On the other hand, we had had such proof of the advantages of free trade that it was useless to expect Englishmen to go back to protection. We could not afford to do so; we lived by our export trade with other nations, and if we handicapped our exporters, and so made it more difficult and expensive for them to manufacture the goods in which they dealt, we might say good-bye to a large portion of our export trade. In one respect the McKinley tariff was an advantage to us, because America possessed such enormous natural advantages, that when once she adopted free trade she would run many of our manufacturers very hard indeed. Reference had been made to the decline in American shipping since iron had taken the place of wood, and so long as she enhanced the price of iron by the heavy duty imposed, so long would England maintain her superiority in that field of enterprise which yielded a large amount of her wealth. A comparison had been made between the tonnage going through the Detroit canal and Suez canal, and between that entering Chicago and Liverpool respectively; but such comparisons were illusory unless the tonnage were multiplied by the mileage it had been carried. He regretted that so much attention had been given to what was really a side issue—the Chicago Exhibition—though it was very useful to have had Sir Henry Wood's clear exposition of the matter. He was glad to hear that British manufacturers would be well represented, but it must be remembered that we started Exhibitions, and were, perhaps, beginning to get a little tired of them. He did not think Englishmen need be in much fear of being ruined by the Nicaraguan Canal, even when it had been successfully accomplished. New York would be no nearer Africa than it was now; and it was in that direction that our manufacturers must look for an extension of their trade. With such a large Colonial Empire, it was not altogether a bad thing to be driven to rely on our own resources instead of on foreigners, and we should then be independent of the protective policy of anyone.

Mr. OLIVER WILLIAMS asked if it was not understood that the Exhibition at Chicago would be equivalent to a bonded warehouse, so that the tariff would not affect goods merely sent for exhibition.

The CHAIRMAN said that was so.

Mr. HALSEY did not understand why the factory should go to the cotton field, as was suggested in the paper; why should it not go to the coal and iron, as it had done in England, and to the place where there was cheap labour.

The CHAIRMAN then proposed a vote of thanks to Mr. McCormick, which was carried unanimously.

Mr. McCORMICK, in acknowledging the compliment, said the cotton mills in England went to the coal and iron fields; and as enormous beds of coal and iron had recently been found in the South, it led him to think that the cotton mills would be established there also.

Correspondence.

SPONTANEOUS COMBUSTION OF COAL.

Mr. W. Cave Thomas advances the theory that pressure of the superincumbent mass is the chief factor in leading to the spontaneous ignition of coal. This idea is by no means new, and can easily be shown to be utterly fallacious. Supposing a cargo of coal to be 33 feet deep, and to be solid the weight carried by the lowest portion would be a little under 20 lbs. on the square inch; and if Mr. Thomas will take a lump of coal of a kind known to be liable to spontaneous ignition, and will bring ten times that pressure to bear upon it, he will find that any rise in temperature is so slight that he will have difficulty in recording it. If he will then powder the same coal and place it in a large square biscuit tin, and will keep it in the oven at a temperature of a little over 100° C. for some hours, he will find that the coal catches fire although no pressure is upon it. In masses of coal the ignition always take place at the bottom, because it is at this part that the maximum temperature is attained, as it is furthest away from the cooling action of the air, and is surrounded with the largest amount of non-conducting material.

VIVIAN B. LEWES.

MEETINGS OF THE SOCIETY.

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock:—

APRIL 12. — C. PURDON CLARKE, C.I.E., "English Brocades and Figured Silks." The LORD MASHAM will preside.

CANTOR LECTURES.

Monday evenings, at Eight o'clock:—

BENNETT H. BROUGH, Assoc.R.S.M., F.G.S., "Mine Surveying." Three Lectures.

LECTURE III.—APRIL 11. — *Levelling.* — The level and staff for underground use—Applications of levelling in mining operations—The Carrara marble railway—Aërial wire ropeways—Hydraulic mining ditches—The St. Gothard, Mont Cenis, and Croton aqueduct tunnels—The Ernst-August adit-level—Mapping bore-holes.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 11...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lecture.) Mr. Bennet H. Brough, "Mine Surveying." (Lecture III.)

Scottish Society of Arts, 117, George-street, Edinburgh, 8 p.m. 1. Professor Stanfield, "Ore Concentration (New Dry Method);" illustrated by working model of machine, and lantern slides. 2. Dr. W. G. Black, "A Floating Rain Gauge and Evaporator for Ponds." 3. Mr. William Gray, "Heat."

Geographical, University of London, Burlington-gardens, W., 8½ p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

Victoria Institute, 1a, Adelphi-terrace, W.C., 8 p.m. Professor Geikie, "The Glacial Period."

TUESDAY, APRIL 12...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr. C. Purdon Clarke, "English Brocades and Figured Silks."

Royal Institution, Albemarle-street, W., 3 p.m.

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. H. Alfred Roechling's paper, "The Sewage-Farms of Berlin."

Photographic, 5A, Pall-mall East, S.W., 8 p.m.

Colonial Institute, Whitehall Rooms, Hotel Metropole, Whitehall-place, S.W., 8 p.m. Mr. E. A. Maund, "Mashonaland, and its Development."

Asiatic, 22, Albemarle-street, W., 4 p.m.

WEDNESDAY, APRIL 13...Pharmaceutical, 17, Bloomsbury-square, W.C., 8 p.m.

Royal Literary Fund, 7, Adelphi-terrace, W.C., 3 p.m.

Photographic Club, Anderton's Hotel, Fleet-street, E.C., 8 p.m. Mr. J. Traill Taylor, "The Choice of Lenses."

Civil and Mechanical Engineers, 12, Delahay-street, S.W., 7 p.m. Mr. G. Macdonnel Lemmi, "Remarks on the Development of Ordnance."

THURSDAY, APRIL 14...Institute of Architecture, Science, and Art, Dundee, 8 p.m. Mr. W. D. M'Kay, "The Art of the Low Countries."

Mathematical, 22, Albemarle-street, W., 8 p.m.

CORRECTION.—In the Obituary notice of the late Sir Francis Charles Knowles, Bart., F.R.S., in the last number of the *Journal* (p. 509), the name was unfortunately misprinted as "Knollys."

The Telegraphic Address of the Society of Arts, and of the Royal Commission for the Chicago Exhibition, is "Praxiteles, London."

Journal of the Society of Arts.

No. 2,056. Vol. XL.

FRIDAY, APRIL 15, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

CANTOR LECTURES.

On Monday evening, 11th inst., Mr. BENNETT H. BROUGH, Assoc.R.S.M., F.G.S., delivered the third and last lecture of the course on "Mine Surveying."

On the motion of the CHAIRMAN (Professor W. C. Roberts-Austen, C.B., F.R.S.), the thanks of the meeting were voted to Mr. Brough for his interesting course of lectures.

The lectures will be printed in the *Journal* during the autumn recess.

Chicago Exhibition, 1893.

The Royal Commission have received information that Her Majesty's Government have it in contemplation to increase the grant of £25,000 made for the purposes of the British Section, in order that the charges for space may be remitted. As soon as they receive information of the final decision of the Government on this point, they will communicate immediately to the exhibitors, and will arrange for the payments already received to be returned.

PUBLIC MEETING AT MANCHESTER.

A meeting of manufacturers, merchants, and others interested in the Exhibition was held on Friday afternoon, 8th inst., at the Manchester Town Hall.

The MAYOR (Mr. Alderman Leech) who presided said that considering the importance of the Exhibition, he readily consented to the wish expressed by the Royal Commission that he should call a public meeting to consider the matter. The Exhibition would be on perhaps a larger scale than any yet held, and the inhabitants of Chicago had themselves formed a guarantee fund of £2,000,000 sterling in order to ensure its success. The English Government had voted £25,000 to assist the representation of this country at the Exhibition, but it was believed that this sum would be increased to £60,000. No doubt there was some soreness in this country with regard to the M'Kinley Tariff; but other countries had to submit to the same regulations, and France and Germany were making great efforts to be thoroughly represented.

Sir DOUGLAS GALTON, K.C.B., said he and his fellow Commissioners had come down here because they felt the enormous importance of having England properly represented at the Chicago Exhibition. He might be met by remarks as to the McKinley tariff, but it was his very strong opinion that our manufactnrers benefited by the protection which existed in America. If the Americans had not had protection for their manufactures and industries, they would now be competing with us more than any other nation, in every market in the world, and probably, with their wonderful skill and talent, would be beating us. It was not so much for the sale of our goods in the United States that we ought to exhibit at this Exhibition. The Exhibition would not only represent the United States, but would be an exhibition on the part of all nations in the world. The South American Republics, with which we had a large trade, would be fully represented. There would be China and Japan, and also other nations to whom we now send goods. There would, in addition, be a strong representation of the industries of Germany and France. The Government were extremely desirous that England should be thoroughly represented, and for that reason they were now considering the question of increasing the amount to be devoted to this purpose from £25,000 to £60,000. The increase in the grant would enable them to offer space to the exhibitors free of charge. The Royal Commission earnestly hoped that the various great industrial centres of England would take up this question, and organise exhibits of their various industries.

Mr. R. M'CORMICK, the Commissioner from Chicago, said it gave him great pleasure to be in Manchester. In America, Manchester was regarded as the Chicago of Great Britain. There was, however, a marked difference between the two places. Manchester was the centre of a great manufacturing district, and Chicago was the centre of a great agricultural district. The population of each place was about 1,000,000, and, like Manchester, Chicago was about to make a canal which would save the transshipment of goods. He did not propose to discuss the M'Kinley Tariff, but he would like to point out that, notwithstanding that tariff, the United States were still by far our best customers. Chicago, moreover, was the centre of a large district where there had been a great deal of opposition to the tariff. By sending goods to the Exhibition, English manufacturers would be able to demonstrate to the merchants

and agriculturists of the Great West how much cheaper they could sell their goods without the tariff. Exhibitors would be allowed to mark on their goods the cost to the buyer at Chicago without the tariff, and the cost with the tariff. This would be a practical demonstration of the benefit there would be in doing away with the tariff. The Chicago Exhibition would be absolutely unique. Hitherto exhibitions had been held in countries which were not only large manufacturers but large exporters of manufactured goods. The United States, on the other hand, did not export manufactured goods, or at any rate not in large quantities. It exported raw materials, and principally to this country, taking back from us manufactured goods. Efforts were about to be made in the United States to secure a share of the cotton trade with South America, which had hitherto been controlled by Great Britain.

Sir PHILIP CUNLIFFE-OWEN, K.C.B., K.C.M.G., said Manchester was always first in every good work, and he was sure the Manchester manufacturers would take a prominent part in this exhibition. It would be no ordinary exhibition. It would not be an exhibition for purposes of amusement, like that at Paris. It would be an exhibition for business men and intended for business purposes. He hoped England would make a good exhibit, and show what the old country could do. It would be a great mistake if we did not offer the right hand of fellowship to the United States on this occasion. It would, moreover, be very important to show the American people the prices at which our goods could be manufactured, and what it cost them to have a tariff.

Sir H. TRUEMAN WOOD said the arrangements were so far completed that, even if no further progress was made with the British section, England would have no reason to be ashamed of her show there. The greater portion of the space placed at the disposal of the Royal Commission was already occupied, and he hoped Manchester would come forward.

Mr. Alderman BAILEY said he did not know a single engineer in this district who proposed to be an exhibitor, and he was not at all surprised. The Americans had already copied our machinery to a great extent, and why should we, at our own cost, give them further facilities to do so.

Mr. MCCORMICK, in answer to Mr. E. Sowerbutts, said that steps would be taken to protect, while it was in America, any article which was patented here, but not in that country. He further remarked that the English manufacturers could not please their brethren in America better than by staying away. The Americans were beginning to be exporters of iron goods, and it would quite suit them if that class of goods was not represented from this country.

The MAYOR OF OLDHAM (Mr. Alderman Emmott) said the makers of machinery in England did most of their business, he believed, with foreign countries; and, as they sometimes complained that their goods were not known, he did not see why they should object to the advertisement they would get at Chicago.

Votes of thanks to the Royal Commissioners and to Mr. McCormick were passed.

APPLICATIONS FOR SPACE IN THE BRITISH SECTION.

Intending exhibitors are reminded that applications for space must be made immediately, as the allotment of space is now proceeding. Most of the available space is now occupied, and no time should therefore be lost by manufacturers desiring to be represented.

All applications must be made upon forms to be obtained from the Secretary of the Commission at their offices, Society of Arts, John-street, Adelphi, London, W.C. They must be sent in, properly filled up, and addressed to the Secretary, as above.

Proceedings of the Society.

FOREIGN & COLONIAL SECTION.

Tuesday, April 5th, 1892; Sir CHARLES TUPPER, G.C.M.G., C.B., in the chair.

The paper read was—

THE RED AND WHITE RACES IN MANITOBA AND THE NORTH-WEST.

BY THE REV. JOHN MACLEAN, D.D.

To the West! is the inspiring cry of the young hearts of the Old World. The development of the western world is the answer to this joyous shout of young Britain. The tide of conquest is flowing toward the majestic mountains of Greater Canada, and to-day the songs of love and labour may be heard upon the prairies and upon the hills of the fairest land, whose dwellers reverently uncover their heads as they gaze upon the unfurled flag of a thousand battles.

When I travelled westward, in the spring of 1880, under the impulse of duty, the prairies resounded with the tread of tens of thousands of buffalo. Courageous would that man be who would dare to tell to a British

audience the numbers in the vast herds of buffalo which he has seen in the early years on the western plains. The possibility of grasping the immensity of numbers may be helped by the assurance that, when we visited that wondrous land for four successive years, as we journeyed for hundreds of miles, the camp fires were made of the excrement of these animals, and this lay in such abundance, that, within an area of fifty yards, sufficient was obtained for all the necessary purposes of fire for cooking.

The barn-yards and pasture fields of England do not offer such evidence of the presence of cattle as we saw for hundreds of miles all over the country. I have not the note books with me containing the exact statistics showing the expenditure of money in the purchase of bones in the Moosejaw district, during a period of five years, but convincing evidence can be given to prove that, within an area of fifty miles, several hundred thousand of these animals have died. Eastward they roamed for several hundred miles, and westward for five hundred, while, southward and northward, the range of the buffalo must be reckoned by more than a thousand miles. What will be the destiny of a land of such abounding fruitfulness, in sustaining countless numbers of animals, whose life and death have prepared the soil for the millions of men and women who shall ultimately claim these fertile acres as an undying heritage for posterity? The red men of the West, undaunted, rode over the boundless plains in quest of food. Men of daring—members of the white race—greedy of gain, and delighting in adventnre, sought out the hardy children of the wilderness, and henceforth an increased value was placed upon the hides of the buffalo. Liquor was introduced, and debauchery speedily followed. Missionaries and loyal-hearted citizens interposed, and, in answer to their petitions, the Canadian Government sent forth, in the year 1874, the North-West Mounted Police. Faithful in the discharge of their duties, these men won the hearts of the Indians, destroyed the influence of the *régime* of the whiskey-traders; but it was too late to save the buffaloes, for they fell before advancing civilisation, and in its interests, so that the countless herds have gone to return no more. The buffaloes were slain, the Indians became destitute, and civilisation advanced. Had they remained, the native culture of the red men would not have rapidly died away. The Union Jack and the red-coats of the mounted police are respected by the Indians, as they represent just treatment, the power of liberty and protection on the throne and behind it. They speak gravely in their lodges of these matters, and the Great Mother is synonymous with justice, peace, and strength. Unbroken treaties are the consequence of this unity of sentiment among the Canadian Indians, and not a single Indian war degrades the annals of our glory. The laws of England are, to them, a strong bulwark, and if the Great Mother has issued a decree, fearlessly will they defend the honour and glory of the Empire.

There exists amongst the native tribes a distinctive civilisation, differing greatly from the culture of the white race, yet nevertheless true. It is a civilisation of nature, not a culture derived from books. Cruel savages they are not, and there are not any peoples more devoted to their religious rites than are these men, as shown by their belief in prayer, the duty of sacrifice, the existence of Deity, the immortality of the soul, and the knowledge of a future state. The sun dance, sweat-lodge, and gifts to the great sun reveal the piety of these prairie heroes. Traditions of creation, the origin of man, the flood, the advent of a teacher for the race, are numerous. Polygamy, as a consequence of war, is rapidly passing away before nature's wise law, which makes provision for the equality of the sexes. A strong, accurate, euphonious, and expansive language exists, which reveals the wisdom and strength inherent in the intellectual life of these men.

In the interests of civilisation, to maintain peace between the red and white races, and to begin a course of training among the Indians, it became necessary to select tracts of land for distinctive occupation of the natives, which are called "reservations." These reservations have invariably been granted to the natives after they have selected them, a worthy act on the part of the Government. Peaceable and contented, the people have dwelt upon these beautiful tracts of land. The reservations are well watered, partly wooded, and the soil and pasture is excellent. The departure of the buffalo predicted utter destitution and death, but the authorities were not slow to supply the wants of the starving people, and a system of feeding was instituted, which has been continued in a modified manner upon some of the reserves until the present time. The reserves and people have been placed under the care of agents and officials who belong to the Indian Department. One of the principal objects of

the Indian Department has been to teach the people farming. Success has attended the labours of the agents and farming instructors. The average reader or traveller, ignorant of the principles of ethnology or sociology, makes serious mistakes in judging the results of all the expenditure of money and men, and in believing that the demands made for the outlay are unjust. Before the advent of the white men, the Indian was a hunter. He toiled hard to support his family, and was oftentimes absent for weeks, seeking to procure the necessaries of life for his family. When he returned, hungry and tired, from his hunting expedition, he threw down the produce of the chase, which was claimed by his wife. The few days spent at home in the camp were used in gathering strength for future toil. The wood and water for the household were procured by his wife; and the small patch of ground, which represented the interests of agriculture, was carefully tended by the female portion of the house. Hunting was a manly occupation, and agriculture was a trade which belonged to the women. So strongly imbedded were these divisions of labour in the minds of the people, that no one was bold enough to defy them; and there were not found men and women in the tribes who dared to subject themselves to the jeers of their fellows, by choosing the trade which belonged to the other sex. When, in the early years, I requested a Blackfoot Indian to saw some wood, I received the reply, "I will bring my wives to saw the wood." Requesting another to carry some water, he said, "Do you think I am a woman?" If white men and women recognise the division of labour among the sexes, and will not interfere with the occupations of each other, how can we expect the natives to break through the customs of the camps? Missionary labour, political and religious, has aimed at the overthrow of these distinctions, but this cannot be done within a few years. Many centuries have passed by since our ancestors rode along the banks of the rivers, securing pasturage for their cattle, wandering over vast expanses of country, unsettled, contentious and savage. The civilised man of the 19th century is not the product of a few decades, but of centuries. Surely it is unscientific to ask for an ideal white man to be evolved from the members of the red race within a few years. We cannot compare the races, but we may contrast them. There is a culture of the red race as there exists a civilisation of the white race. If there is to be a grafting of the old world customs of the natives of the new, there will be failure. The exaltation of the red man will become a reality through the destruction of the native customs, and this can be done through a gradual undermining of the life and thought of the dwellers in the camps upon the plains.

The thorough acceptance of the modes of life and thinking of the white race by the natives, must be the work of many, very many years, and unjust is that man who demands results within two or three decades, or condemns men and methods, because the people do not speedily conform to the ideas of the critic.

The Indian schools upon the reservations are slowly changing the traditions, customs, and language of the people. Not fully have the natives grasped the ideas inherent in our systems of education. So antagonistic are our methods, and so subtle our principles, that the men who are ever living for the present fail to appreciate the benefits which lie so far distant. If it can be shown that by means of education the men will become better hunters, and the women tan the skins and make mocassins better than in former years, eagerly will they grasp at this kind of knowledge. Slowly but surely will education win its way into the hearts and homes of the red men, uniting them in one common interest. Industrial schools have been established with the noble aim of uplifting the children of the natives of the west. The wise treatment of the red men by the authorities has maintained peace, and made it possible among a warlike people to introduce the arts of civilisation, build railroads, villages, and towns, and further the interests of emigration. The settler's hut and the miner's shanty remain in peace, unmolested, and the inhabitants have no dread of danger, for there is none. Our mothers and daughters welcome the natives, and purchase game or wild fruits, or help them with a pittance from their small stores of goods.

European civilisation has sounded the war-cry of destiny in the overthrow of all the native tribes. Step by step, as the white man advances, the red man retreats, or bows his head and dies. Not so much through the introduction of disease—although this is fatal—as by the more powerful factor in civilisation, the limitation of freedom, is the destruction of the native races effected. These people fade away, as the story of statistics invariably tells us. The Blue-books show a maintenance of strength in numbers, but it is

the strength which is undermined. Decrease by absorption is the law. In tribes far removed from the haunts of the white man, there is progression in numbers, but, so soon as the white race appears, there begins declension. This is an unwritten law, which we may retard in its work, but which we cannot defeat. No man loves freedom so intensely as the dwellers on the prairies. He roams at will across the plains, monarch of all his eye surveys: the countless herds of buffaloes he claims for his possessions, and he owns no man as lord and master. The advent of the white man is conquest, and the heroes of the plains are destined to occupy an inferior position. Frequently do we see the aged man slowly wending his weary way to the camp, with his hand upon his mouth, singing the song of the shadow. If we accost him, to ask the cause of his sorrow, with a wave of his hand, after a sign of recognition, he will point to the prairies, and recount the years when the buffalo roamed in tens of thousands, the warriors were numerous, and the lands were his property, but now the towns of the white men are there, the fences express the claim of the pale-face, and cattle have replaced the bison. "Gone! they are all gone!" he sighs, and he departs to his lodge to die a broken-hearted man. Not by ill-treatment are the natives decreasing, but they have been conquered, and their ultimate destiny is extinction through death, and absorption by the white race.

Greater Canada, from the eastern boundary of Manitoba to the western limit of Alberta, and from the International boundary to the North Pole, is a vast expanse of territory, larger than the combined land areas of the following countries:—England, Scotland, Ireland, Wales, France, Spain, Portugal, Italy, Norway, Sweden, the German Empire, Japan, and China, exclusive of her dependencies. These countries have a united population of 600,000,000, and if Greater Canada is larger, making allowance for cold and inequalities of soil, surely there could be maintained at least one-half, or a combined population of 300,000,000. This is only a small portion of our dominion. Winnipeg occupies a central position between the Atlantic and Pacific, and the centres of population must travel westward towards the mountains and prairies, and the golden sea.

In such a vast country the soil is of various qualities, adapted for every kind of grain and fruit. In the Dominion, there exists every kind of climate, from the soft breezes of Southern Alberta and British Columbia to the intense cold of the Arctic regions. The winters of Manitoba differ from those of Assiniboia, Alberta, and Saskatchewan. The invigorating winter of Manitoba is productive of health and manhood. Enterprising men and women in quest of health and comfort prefer the cold of Manitoba to the damp temperate breezes of more southern climes. So vast is the Canadian North-West, that the settler can choose any kind of soil (prairie land or forest, with water or hay lands suitable for grazing or farming), and varieties of climate can there be found. The air is rare, and the cold weather does not produce that raw feeling which belongs to moist climes. It is invigorating, giving that bracing sensation which is the delight of young manhood. The Chinook winds of Alberta and Assiniboia cause the ice in the rivers to break up several times during the winter, and the snow upon the prairies departs at the presence of this warm wind. I have listened to the *sough* of this western wind in the mountains, and gazed upon the mist rising, indicating the coming of the wind. So soon as it comes, the cattle in the villages and *coulees* speedily seek the prairies, as the Indians leave their shelter in the bush. It is this delightful breeze which has given Alberta and Assiniboia the fame of the Range country, where roam the countless herds of wild cattle and horses, unhoused and unfed, yet fatter and sleeker after the severity of the winter than the best stall-fed cattle of eastern lands.

The coalfields of the North-West are very wide. Along the rivers the coal crops out in seams, varying from four feet to ten and twelve feet in thickness. Bituminous and anthracite coal, of excellent quality, is found in abundance, from the St. Mary's River, in Southern Alberta, to Edmonton, in Northern Alberta, and, from the coalfields of Manitoba, to Banff, in the Rocky Mountains. The coal mines at Lethbridge and Anthracite are sufficient proof of the wealth and possibilities of this industry. Pottery-clay, of good quality, and minerals of various kinds are to be found throughout the territories, and not far distant from the line of railroad. Timber is abundant in the district of Saskatchewan and the northern and western portions of Alberta.

So soon as the immigrant enters Manitoba or the North-West, he receives from the Government a homestead of 160 acres, upon which he performs the settlers' duties for three years, when it becomes his sole property. The

soil is productive, and the yield of grain abundant. There are good and bad sections in every district, as we find such in every country. Failures there will be, if men lack common sense and energy. The same contingencies apply to farming in Canada as in other lands, gold and silver pieces are not strewn upon the surface of the prairie, but they lie imbedded in the soil, and the plough will bring them forth. New lands require new and improved methods of farming, and the men who can adapt themselves to the country will soon reach positions of comfort, and enjoy a social status which they cannot attain within the same period in the Old World. The wheat fields of Manitoba and the North-West are eminently productive, when the settlers expend the labour necessary for proper fertilisation. The railroad cars which annually are sent to Ontario filled with the specimen products of the field and garden from the districts of Calgary, Regina, Brandon, and Winnipeg, astonish the people who dwell in Eastern Canada, giving rise to the belief that these exhibits are forced. Such, however, is not the case. Very fine garden produce has been exhibited, and as an evidence of what can be done, there have been shown cabbages, grown at Qu'Appelle and Edmonton, two widely separated districts, the diameter of which was 2½ feet, and the solid head 1½ feet.

In the Range country the buffalo roamed in thousands, and when the herds were destroyed, civilised man introduced domestic cattle. The grasses of the ranching districts are very nutritious, insomuch that when travelling in the early years in Southern Alberta, we fed our horses solely on the buffalo grass, popularly termed "bunch grass." One of my friends now resident at Lethbridge, within an area of 100 yards square at the foot of the Rocky Mountains, gathered in the spring specimens of 100 varieties of flowers. Cattle and horses, sheep and hogs, can be bred with little expense, save that which is incurred in labour. In such a country we seem to be lost through lack of men and money to develop its resources. Here is a field for the development of industries. Tanneries, woollen factories, cheese and butter factories, and various other branches of industry, can be carried on successfully, and yet we are without these, except in rare instances.

The settlers in Manitoba and the North-West are sober and industrious; and so soon as the first difficulties of settlement are overcome, schools and churches are begun. Nine years have not passed by since the first school was started in the Canadian North-West, and at the present time there are over 250 schools scattered over the territories. Education is free and compulsory. There are public and grammar or high schools; the headmasters of the latter must be graduates in arts of a British or Canadian university. The effects of our educational system are seen in a sturdy manhood and an industrious people. In the log-shanty of the settler oftentimes we meet graduates of Oxford and Cambridge and young men who have been trained in the universities of Glasgow, Edinburgh, and Dublin. Sometimes we are entertained in the settler's home by lady graduates of our colleges, and gracefully they perform their domestic duties, although bereft of the blessings of civilised life. Culture and manual labour are companions on the prairie.

The growth of our cities is rapid and stable. Winnipeg and Calgary are notable instances of speedy and permanent development. Unhampered by the vested interests of old trades and professions, the most modern appliances of art and science are sought and used in the development of industry. Thus we have in Winnipeg, Brandon, Regina, Moosejaw, and Calgary the electric light and telephone. In the three last-mentioned places there never was any gas, hence the transition was easy from the oil lamp to the electric light. Portage La Prairie, Moosomin, Prince Albert, Medicine Hat, Lethbridge, and Edmonton have developed rapidly, and numerous towns and villages are springing up as the settlers advance. Twelve years progress marks the beginning and growth of villages and towns in Manitoba and the North-West.

Since the building of the Canadian Pacific Railroad, the country has been studied as it never was before; and settlers from many lands have found their way towards the prairies and mountains of that western land. The construction of this railroad was attended with an almost absence of crime, owing to the prohibition of liquor and to the executive ability displayed in its management.

Representatives of the leading religious denominations are to be found toiling nobly upon the Indian reservations and among the settlers. Harmoniously they toil for the uplifting of the people, and the strengthening of the bonds of patriotism and religion.

The future of Manitoba and the North-West will depend largely upon the classes of settlers introduced. The tourist will find in the mountains scenery unexcelled, vigour and pleasure

in the National-park at Banff, with its hot springs of Continental fame. In the harvest time, upon the prairies, he will gaze enraptured upon the wheat-fields of the west, and, under the shadow of the Rockies, the herds of cattle and horses will reveal a new industry, destined to assume gigantic proportions at no distant date. We have faith in our country and the people. Let doubting ones come to our western land, and they will return with knowledge increased, and love begotten for the fairest colony of the British Empire.

DISCUSSION.

Mr. C. M. KENNEDY, C.B., said in the first place he wished to thank his friend Sir Charles Tupper for taking the chair that evening. In him they recognised a statesman who had rendered great services to the best interest of the Empire—who, at home, took a leading part in the formation of the Dominion—a most important event in colonial history; and who, as High Commissioner in London, had on every occasion sought to unite and strengthen the interests of the mother country and the colonies. They were glad to have him present that evening, and hoped to see him amongst them on many future occasions. As regards the very interesting paper to which they had listened, they had to consider the topics brought before them from many points of view. They possessed the great interest which a narrative of personal experience and work well performed always possessed, and opened out questions which bore on some of the most interesting problems of the history of the human race. They were particularly appropriate to us at the present time, as the Society was charged with responsible duties in connection with the forthcoming Exhibition in America. It is now four centuries since what was termed, in those days, "the great news" spread over Europe that European navigators had found, far off in what was then termed the region of the setting sun, islands rich in treasures, lying, as it was thought, off the coast of India and Cathay. The land which Dr. Maclean had described was a veritable land of promise to emigrants; and if, in present circumstances, men had to leave the old country, in British North America, they would not find themselves strangers; they would find there a land of free institutions, and would remain under the flag of the old country. They would not be misled and preyed upon as emigrants often were who went to alien shores. He thought the paper would be a valuable contribution to the *Journal*, and hoped the information contained in it would thus become widely known.

The CHAIRMAN said he was quite prepared to expect an interesting statement from Dr. Maclean, knowing that he had an opportunity of spending several years among the Indians of Manitoba, and the North-West, so that he was quite certain he would bring to our instruction a great deal of insight into the habits and manners of that people, but he confessed he was hardly prepared to learn that the art of scalping was an evidence of a high form of civilisation. He quite agreed with Dr. Maclean in regarding it as a very *capital* illustration of civilisation, and there was no doubt at all that a great moral underlies the statement that he had made in that respect, and that was that in order to judge, especially a savage people, or those who were called a savage people, people with manners and customs unlike our own, it was necessary to put oneself as far as possible in their place, and to look at this action from the standpoint which they occupied, and not from that occupied by a different people. He was quite prepared to confirm the statement as to the loyalty of the Indians in Canada to the Queen. It appeared from the most interesting book of Milton and Cheadle that the then savage tribes of Rupert's Land had a marked respect for her Majesty the Queen, and evinced on all occasions the greatest possible loyalty. He had himself had an opportunity of seeing something of that in his first visit to Fort Garry, or Winnipeg as it was then called, about 22 years ago. Manitoba was then in the occupation of Riel, who had incited a rebellion and induced the French half breeds to join with him. The communication with the north-west territory was stopped by Riel, but he (the Chairman) had occasion to pay him a visit. Having to adopt the custom of sleeping in the open air with the thermometer 30° below zero, he was able to bear testimony to the fact that, having travelled no less than 400 miles going and returning in that way, this occasioned no discomfort, and he never knew what it was to be cold, except on one night when a snow storm obliged them to put up the tent. In the journey from Fort Breckonbridge to the boundaries of the north-west territory, a distance of some 200 miles, he only came across one house, namely, at York-town, which was about half-way. The line he travelled from Fort Breckonbridge to the boundary of Canada, 200 miles, was the scene of the Sioux massacre of 1862, when the Sioux Indians rose in revolt against the United States authority, and burned every house to the ground, slaughtering the inhabitants for the entire distance. The single house to which he had referred, was that of the Hudson Bay Company, in which he spent the night, and the person who was in charge of the post at the time of the massacre, and his wife, remained in perfect safety in consequence of putting a little Hudson Bay Company's flag over it. When the Indians came to it, bringing fire and slaughter in their track, they said, "That is the queen," and they allowed the man and his wife to remain in perfect safety. He mentioned that as an illustration, and took the opportunity of saying that that was largely owing to the fact that the Hudson Bay Company, who then had under their control the whole of the great Rupert's Land, had adopted a policy of fairness and justice to the Indians which inspired them with

respect and confidence in the flag of England. The same thing was illustrated in a most striking manner from 1872 to 1876, when the boundary was being surveyed from the lake of the woods to the foot of the Rocky Mountains, a distance of 600 miles between the United States and the north-west territory of Canada. This work was performed by a joint Commission, one formed by the United States of America, and the other by the British Government. The gentleman in charge of the survey, her Majesty's Commissioner, required the assistance and support of no person except the staff and the necessary people to provide for the work and sustenance of the party, while the American Commissioner alongside of him in the same country had an army at his back, and could not advance a mile without the presence of a large force of United States troops. The only danger that any of the British party ever encountered was when he purchased a hat or a pair of boots of American construction, and strayed away from the party, being thus liable to be mistaken for a citizen of the United States. As Dr. Maclean had shown, this matter was all now changed by the advancing civilisation of the Indian; all the dangers that were undergone with these then considered savage tribes—and judged by our standpoint they had a great many of the traits of savage life—were changed by the advance of civilisation. He was glad to take this opportunity of bearing testimony to the deep obligation that was due to those missionaries of the cross, the clergymen of the Roman Catholic and of the Protestant churches who, in the earliest history of that country, long before the commencement of its occupation by civilised parties at all, had devoted with unstinted labour and toil their lives and services to civilise the Indians. Readers of those charming histories that Parkman had given of Indian life both in Canada and in the north-western and northern States would bear out the fact of the devoted labourers and missionaries who had spent the whole of their lives in Christianising Indians. He was glad to hear Dr. Maclean bear testimony to the manner in which the Government of Canada had treated the Indians since they came into possession of the country. There was not a foot of ground in Canada which had been obtained from the tribes except by a fair and honest bargain, and the treaties down to the present hour were religiously carried out. The soil had been handed over by the Indians upon terms which they considered satisfactory. Dr. Maclean had spoken of the spots that were reserved for the Indians, but he thought if the sizes of these spots had been given, one would have been greatly astounded. Manitoba and the north-west territory was a splendid wheat-growing district, and it was the best part of the country which had been reserved for the Indians. Now that game had been driven away, the Government of Canada were providing the means of living for the Indians; schools were erected for the children, and the Indians were not only cultivating their land, but at the Agricultural Shows prizes were not infrequently awarded to the Indians in competition with the agriculturists of the country. Many of the Indians were now living in comfortable houses, and adopted, to a large extent, the dress of civilisation. They were making in every respect a steady and most satisfactory advance in reference to the acquisition of those manners and habits which their changed position rendered necessary. The inhabitants of British Columbia were more responsive to the efforts of civilisation than those in other parts. The reason for this was that they had been less devoted to the chase than the plain Indians. It appeared from one of the latest Royal Gazettes which he received, that a proclamation had been issued providing for the enfranchisement of the Indians. The natives had always been treated as minors—as persons for whom the State should act as trustees in the preservation of property, but such was the advance of civilisation that in Ontario it had been found practicable to place them on a much higher level. The same arrangements were now being made in British Columbia, which was entirely owing to the steady advance of civilisation. In conclusion he proposed a hearty vote of thanks to Dr. Maclean for his instructive and interesting paper.

Dr. MACLEAN, in acknowledging the vote, said the size of a reserve spot was very often 100 miles long by 40 miles wide.

INDIAN SECTION.

Thursday, April 7, 1892; Sir JOHN STRACHEY, G.C.S.I., in the chair.

The paper read was—

THE AGRICULTURAL NEEDS OF INDIA.

By DR. J. AUGUSTUS VOELCKER.

To all who have any acquaintance with India, the recurrence of discussions upon the agricultural improvement of that vast empire will not appear more frequent than the importance of the subject demands. The Society of Arts, through its Indian Section, is always ready to avail itself of an opportunity which presents of regarding this question from the most recent point of view, and hence, I take it, I have been asked to bring before the Section, in brief review, the main conclusions formed during my late inquiry into the conditions of Indian agriculture. I may be allowed to consider myself as the third of the successive "inquirers" who, in recent times, have gone out from England to India with this special object, and as the second of those who have been specially deputed by the Council of India.

The first was the late Sir James Caird, whose great services to agriculture we all sincerely acknowledge, and whose loss we all regret. To myself it is a special sorrow that we have not Sir James Caird with us; for not only was it through my selection by him that I was privileged to go to India, but he had also most kindly promised to occupy the chair on the present occasion. I congratulate myself, however, on having the vacant place filled by one who has so deeply interested himself in Indian agriculture as Sir John Strachey has, and who, when in India, did so much towards its improvement.

The second visitor was Professor Wallace, of Edinburgh, who, with the eagerness and activity for which he is distinguished, went out on his own account to inform himself upon the agricultural conditions of India.

The third was myself, charged, like Sir James Caird, with an official mission. Of the special power which the bright intellect and the authoritative weight of experience possessed by Sir James Caird brought to bear upon the subject, I need not remind you; while Prof. Wallace, as a practical agriculturist and teacher, is well known to you also. It was left for me, however, to take up the inquiry from the point of the scientific inquirer rather than of the agricultural, economical, or practical farmer. Hence it is that my treatment of the subject will be somewhat different from that of my predecessors, and different, too, from that of others who have read similar papers before this Society. If, therefore, I confine myself more to the strictly *agricultural* needs, and deal less with such great questions as those of the relations of the State to the cultivators, or of the economical conditions of the country, you will take it that I do so because I feel myself but little qualified to treat of the latter. Again, it will be my object, not to describe what I saw of the agriculture, but to keep myself to such matters as indicate the existence of agricultural *needs* for which a remedy may, I consider, be found. The recurrence, within the last few months, of a time of widespread scarcity, not to say famine, has brought into special prominence the need of turning renewed and serious attention to the agricultural requirements of India, whereby the country may be enabled to provide for the rapid increase of population shown in the recent census returns. The indignation—often only too well justified—of Anglo-Indians of experience, against the *ipse dixits* of "specialists" who go out to India for a few months in the cold season, and then return with ready but impracticable suggestions for improvement of the country's government, trade, institutions, or agriculture, or all of them together, makes me hesitate when entering on the same path. Fortified, however, with the knowledge that I spent over a year upon my inquiry, and that I passed a "hot season" there as well as a "rainy" and a "cold" one, I approach my subject in the honest attempt, while suggesting lines of improvement, to do, nevertheless, no injustice to individuals for whom I have a very high esteem, and who have borne the heat and burden of many a long day in the service of their country, and taken part in the wonderfully able administration of our Indian Empire.

By way of explanation of my presence in India, let me say that the primary reason of my visit was the repeated applications of the Government of India to the Secretary of State to send out to them an agricultural chemist, and to enable them to complete the scheme which had been drawn up by the Imperial Land Revenue and Agricultural Department, with the view of meeting the obligations imposed upon them by the Famine Commissioners of 1879. Into the desirability of this proposal I was instructed to inquire.

Leaving England towards the close of November, 1889, I was absent over 14 months, spending just 13 months in India itself. Excluding Burma and Assam, I visited each of the provinces in two different seasons, and I may fairly say that the greater part of my time was spent in going about the country, with the view of seeing as much as I could of its agriculture. Through the special facilities placed at my disposal by the Government of India, I was enabled to pursue my inquiries under the most favourable auspices, and to enjoy exceptional advantages of meeting with men of experience and of discussing agricultural matters with them. I cannot pass from this without expressing my sincere acknowledgment for the kindness everywhere shown me by those, whether officials or private individuals, to whom I was commended, and to those who provided me with such splendid opportunities of acquainting myself with the subject which I went out to study. With this introduction of the circumstances which led to my going to India, I pass on to my subject proper—the agricultural needs of India, and how they may be met.

Much has been written, and various opinions have been formed, as to the real condition of

Indian agriculture, and, at the outset, I may be expected to state in general terms whether I consider the agriculture good or bad, and whether it is capable of little or of much improvement. Briefly, then, let me say that so many diversities present themselves in the conditions under which Indian agriculture is pursued, that a general opinion can only be given with so much reservation, that it ceases to be general. In many parts, for instance, I have seen magnificent agriculture, which leaves little or no room for improvement; in others, I have seen inferior cultivation, which, it strikes one, might be bettered. But, when the task of improvement is attempted, I am free to confess that it is seen to be surrounded with difficulties such as are not to be met with in English agriculture, and which require careful and special study. At its best, the agriculture is a "picture" such as might be a model to many a British farmer; at its worst, the inferiority is the outcome mainly of the want of natural facilities, a want which presents difficulties probably unequalled in any other country. I do not deny that instances may be met with where inferior cultivation exists alongside superior, but I came to the conclusion that the determining causes are bound up with considerations of a complexity peculiar to India, and which cannot be treated in the same way as one might deal with questions that present themselves in English agriculture. The work of discovering the agricultual needs may not be so hard a one, but that of supplying them will invariably be very difficult. When the cultivated area of a country is split up into small holdings of five acres or less, when capital is correspondingly small, and the numbers living on the holdings are by contrast great, when the land is subdivided among the members of a family, and they refuse to migrate elsewhere, it becomes hard to say how to proceed in the way of improvement. I cannot do better than quote here the words of one to whom I am indebted for much of the insight I have have had into this subject. I refer to Mr. R. H. Elliot, of Kelso, with whom I travelled to India, and with whom I subsequently stayed in Mysore. In a paper read before this Society, in 1875, he said:—

"If, indeed, I could put nine-tenths of the inhabitants to the sword, take their capital, and hand it over to the survivors, then divide the best of the country into 200 acre farms, or farms of sufficient size to enable them to spare a considerable portion of the land for growing cattle fodder; and if, in addition, I could destroy the whole social system of the Hindoos, prevent the subdivision of the land, teach the people to emigrate . . . . remove their objections to killing off the old and worthless cattle . . . . and finally overcome their objections to the use of night-soil. If I could effect all that, I could easily put Indian agriculture on a satisfactory footing. But, in the absence of such a possibility, I will defy anyone to do more than produce, by slow and painful steps, some amelioration of the existing state of things."

These are, in the main, the views I too have formed; and I am convinced that the work of improvement will be a slow and a difficult one. A circumstance, which tells much in favour of this conclusion is, that wherever I have found an English landholder with native tenants, he has invariably left them to pursue their agriculture in their own way, and has not set about importing English methods or English implements upon his estate, but has been content to introduce this or that improvement just as he has seen the opportunity for its successful *adoption*. Sir James Caird expressed himself as assured of the "practical ability and knowledge of the cultivators of India," and the Famine Commissioners clearly stated their conviction that the work of improvement must be on *native* lines, and be the outcome of careful inquiry into existing methods and practices. In agreement with these authorities, I think that wherever improvement can be made, it will come about by a transfer of the practice of a better part to an inferior one, and by the increase of facilities, such as the supply of water, manure, wood, and grazing, where they are deficient, rather than by any considerable introduction of European methods or implements. That there are differences in the agricultural conditions and practices in different parts of India gives the warrant for believing that an improvement may be effected in the inferior districts; and that much has been already done by Government in supplying facilities to some parts which did not previously possess them, constitutes the ground for urging further advance in this direction. But the line that improvement will take is, I think, that of improvement from *within* rather than from *without*.

I proceed now to consider different ways in which the agricultural needs present themselves, and to attempt to give suggestions for their remedy.

The People as Cultivating Classes.—On the very threshold we are met with a difficulty which acquires a peculiar significance in India, and which is comprehended in the mention

of the word "caste." The fact that, either by religious prejudice or by hereditary practice, some divisions of the people are prevented from being as good cultivators as others, must necessarily constitute a great obstacle to improvement. The Brahmin or Rajput, who thinks it undignified to engage in manual labour, will, as a cultivator, be the inferior of many of the lower but more skilful and laborious castes. The "market-gardener" will cause one to look on with astonishment at his careful toil, and the Kachhi, who does not scruple to make use of night-soil for his land, will show results of his cultivation far ahead of that of those who think the practice a derogatory one. Not only are these "castes" of different agricultural repute, but likewise races, each keeping to his own particular vocation, be he goatherd or grazier, cattle-breeder or milkman, but never departing therefrom. Whether it be caste or prejudice, religious or otherwise, the breaking down of differences in these respects constitutes the first of India's agricultural needs. And yet, progress in this direction will probably be slower than in any other matter, although there are, even at the present time, indications of a change going on. The cultivation of indigo used to be considered an unclean thing, but is now pursued by castes who before would have nothing to do with it; the potato used to be looked on as "flesh," and hence as a thing to be abhorred by Hindoos, but now it is extensively raised; at Nagpur may be seen even Brahmins cultivating sugar-cane by the use of the town-refuse, and Brahmin lads ploughing and doing other field operations with their own hands. The breaking down of caste and of prejudice will undoubtedly be a slow work, but it will most certainly proceed, and more especially when the pressure of circumstances obliges the adoption of the more remunerative practices of cultivation. It will be effected partly by example, that is, the result of a better practice, and also very materially by the spread of education. The exigencies of circumstances which demand the giving of more attention to the cultivation of the land, and the interest in agriculture aroused in consequence of the spread of education, will be the main factors in weakening those prejudices and lessening those hereditary differences which have stood in the way of the extension of the better agricultural practices. The educational work carried on by Government has thus an important bearing upon the improvement of agriculture.

Climate.—The past agricultural year in England was particularly marked by the absence of sunshine during the ripening of the corn crops and at harvest time. This cannot be said to constitute an agricultural need of India; indeed, the reverse is rather the case; and, under the head of climate, what is generally required is a more certain and more distributed rainfall, with provision of shade and shelter. The alteration or modification of the severities of climate is a matter almost entirely beyond human power. People, cattle, and crops, as well as agricultural practices, are influenced by climate; and it is a factor which has to be reckoned with, but cannot be removed. The most that can be done is to mitigate the evils resulting from its severity; and, in two directions, this may, to a certain extent, be accomplished. If canals and other means of irrigation were to be conveyed to those drier tracts of the country which suffer from a scarcity of water; and if the bare surface of the land could be once again covered with trees and forest, undoubtedly some improvement would be effected in the climatic conditions of India. Everyone is ready to concede the first point; but the influence of trees is not so easily apparent. It cannot be positively asserted that, if there were more trees and forest, an increase of rainfall would be the result. But there is no doubt that a lowering of temperature would be produced, and moisture would be deposited where it would have passed on had the surface been bare and heated. A steady rainfall, distributed over a longer period, would take the place of heavy storms and deluges. The increase in the number of rainy days would be of great value to agriculture, for it would permit of the moisture gradually sinking into the soil, and not, as is too often the case, rushing over the dry surface of the land in a torrent, and being, for the greater part, lost. The growing of trees is accompanied by benefits to the soil itself, for it is held up and bound together by the vegetation that soon covers the surface, and the sun's rays no longer striking directly on the soil and so being reflected off from it, a cooler surface is produced, and, in the end, a moister climate may prevail. During my tour I visited several parts where plantations of trees had been formed and were being carefully reserved, and I found that the influence for good, in a climatic direction alone, was clearly acknowledged. The difficulty in India is to secure tracts sufficiently large to exercise any sensible influence on the climate, but, nevertheless, every attempt to mitigate climatic severity, whether by forming

plantations or by growing trees along roadsides, canal banks, &c., will be work in a right direction. Government offers a certain amount of encouragement to private individuals to grow trees, but, after all, anything on a comprehensive scale, be it the carrying out of irrigation schemes or the formation of plantations and "reserves" of wood, must be the direct work of the State.

Soil.—The agricultural needs connected primarily with the soil are two-fold, viz., that of making the cultivated land more productive, and that of bringing other land under cultivation. A rapidly-increasing population, making, as it does, greater and greater demands upon the soil, calls for an increased production from the soil. With this is bound up the famine problem; and it was the estimate of the late Sir James Caird, that if the produce of cultivated land could be increased by one or two bushels per acre, the difficulty could be solved. The inherent nature of soil is fixed by geological conditions, and can only be to a limited extent altered; but its productive power may be increased by such means as the supply to it of sufficient water and manure. Taking the case of wheat, the general yield of India does not exceed 10 bushels per acre, as against the 30 bushels of England; but whereas land that receives but scanty rainfall and no manure will give seven bushels per acre only, the produce of irrigated and manured land will range from 13½ to 18 bushels. It has often been asked whether the soil of India is undergoing exhaustion or not, and to this question I gave particular attention. That there is no clear evidence of exhaustion having actually taken place, I am ready to admit, although no one will be prepared to say that the produce is an increasing one. It is argued that, after a time, a certain level is reached, and that this is maintained without further deterioration. Now, in the case of India, what we see is, exportation of crops, such as oil-seeds and wheat, and also of manures; while, even what is consumed by the people and by cattle is not returned to the land the constituents of which have been drawn upon. Manure is not properly preserved, or it is burnt as fuel; the urine of cattle is wasted, bones and oil-seed refuse are exported, and night-soil is almost universally neglected. In the end, therefore, the soil is having greater demands made upon it; and what is taken off is not being replaced. Whether deterioration will be marked or not, the soil, at all events, will not be enabled to provide the requirements of an increasing population, unless there be a change in the present agricultural system. In brief, it will be necessary to supply to it water and manure where either or both are deficient.

Cultivation has already extended so far, that there is little land left which can be taken up; but there are some kinds of land existing amid the cultivated area which have been considered unculturable. These are mainly the vast salty plains known as *usar* land, the soil of which is impregnated with soda-salts, forming an efflorescence on the surface termed *reh*. Various theories have been put forward to account for the existence of these soda-salts, but their appearance on the surface of soil has been concurrent with the clearing away of forests and the introduction of canals. That canals have directly brought the *reh* I do not think to be the case, but that the water has dissolved the salts and thus supplied one of the elements necessary for bringing them up from below is doubtless true; while the denudation of the land has had the effect of increasing the capillarity of the soil, and so assisting the rise of the salts.

Various methods of reclamation have been tried, and it may be said that it has been shown possible to make *usar* land grow grass, trees, and even crops, by such means as simple enclosure, with exclusion of grazing, heavy manuring, flooding with canal silt, and embanking rain-water upon it. The result, as a financial success, under present circumstances, has not as yet been fully shown, but it is sufficiently complete as to make it certain that if the demand on the land became greater, it would pay quite well to reclaim even *usar* land.

Another class of waste land that may contribute to future cultivation is ravine land, and this, by enclosure and exclusion of grazing for a time, as also by embanking it when necessary, may be covered with trees and shrubs, and may supply stores of fodder, or even crops where sufficiently level.

A third need in regard to the soil is that of obtaining more knowledge about it, and knowledge that can be obtained only by the application of chemical science to its study. In respect of the constituents of soil, their efficiency or deficiency, their supply in the most suitable form, the connection of plant life with the soil on which it grows, and the atmosphere from which it likewise derives nourishment, there are many questions which remain unsolved in Indian agriculture. Such an inquiry as the reclamation of *usar*, for instance, manifestly calls for the employment of chemical science.

Water.—That water is, over a great part of India, one of the chief agricultural needs, has been generally recognised, and Government has not been slow to take up the important question of its artificial supply to tracts that suffer from deficiency of rainfall. Famine is the direct result of failure of rainfall, and hence attention has been most naturally turned to supplementing it, more especially in those tracts which are known as "precarious" ones. It is not the districts where rainfall is lowest that are most subject to famine, for the cultivator will not put in his crops at all here unless he has a sufficiency of water; but it is those where rainful is variable—sometimes failing altogether — that the cultivator is induced to risk the growing of a crop, which, should rain not come, may fail entirely. The ways in which water may be supplied, vary with the geographical and geological conditions, and it is necessary to exercise great care before deciding whether irrigation is to be carried on by canals, by wells, or by other means. In extending canal irrigation, the main object should be to take it where no other available supply of water exists, and to provide for as large an area as possible. Various objections, some of them well-grounded, have been urged against canals, that they have been taken where not needed, that they have raised the water-level of the country, spoiled the wells, obstructed the natural drainage, and brought ill-health to the people, as well as causing the spread of the salty efflorescence *reh*. Undoubtedly, canals have in some cases in the past, as in Orissa and Behar, been taken where they were not required; and, in others, their alignment has been faulty, while, as already noted, canal water may indirectly be connected with the appearance of *reh*. But it must be allowed that the Irrigation Department is now careful to avoid the errors of the past as far as possible. The coming of a canal to a district has certainly, in some instances, been productive of fever and ill-health; but it has also produced an immunity from the ravages of famine, and between the two evils the choice must lie. It has been proposed to try subsoil-drainage as a remedy for water-logged lands, and though the difficulties and cost would be very great, I yet think that in parts which are most affected it might be experimentally tried. In connection both with canals and river-channels, much good might be done by the storing of water in reservoirs, to be used for irrigation purposes. Such reservoirs might be made at the end of canals, or by intercepting river-streams, such as those in Southern India, before they find their way into the sea. The great difficulty in supplying water by flow, whether from canal or storage reservoir of any kind, is to check the wasteful use that is made of it. When water has to be raised by lift, as from a well, it is found that far less is used, and that the cultivation is more careful too. All attempts at charging a water-rate on the quantity used have, however, failed. The over-use of water must tend to remove much of those constituents of the soil which would go to feed the crop, and it induces the over-cropping of the land. The "coldness" attributed to canal water is mainly the result of over-watering, which brings about a cold stagnant state of the soil, as exemplified in the case of badly drained clay land, whereas the well-water applied in lesser amount, and raised by lift, is known as "warm." There are other interesting features distinguishing canal and well-waters, the latter often containing considerable quantities of nitrates and other salts, and when this is the case they are held in special favour for tobacco growing. The water of some other wells is, on the other hand, considered unsuitable, and there is clearly work for the chemist in a study of this subject and of its bearing on agriculture. In some cases, not the supply of water, but the checking of its rapid flow over the land, may be the agricultural need, and the advantage of embanking land has been experienced in many parts, mainly in the Central Provinces.

Though much work has been done by Government in projecting canal irrigation schemes, and in encouraging the making of wells, tanks, and other reservoirs by the inducement of a Government advance at a low rate of interest, very much still remains to be done, and the recent distress in several parts, notably in Madras, consequent on the failure of the monsoon, emphasises the point. At Bellary there are no canals, only a few tanks, and the wells are 45 feet down, the solid rock having to be cut into to make them. Kurnool, Madura, Coimbatore, Ajmere, and Jhansi are other places where irrigation is urgently needed. The difficulty with many of the proposed schemes is, that, unlike most of the existing canals, they cannot be considered as remunerative, but purely as measures of a protective nature. It has been ascertained, too, by inquiry, that it would not in general pay Government to undertake the construction of wells on a large scale, but that this can be better done by the system of advances to

cultivators known as *taccavi*. In the working of this system, however, distinct improvements can be effected, and my experience convinced me that the adoption of this system by the cultivators is almost entirely dependent upon the personal activity and interest of the collector or other Government official of the district. Where this interest is shown, the *taccavi* system is popular, but where difficulties are thrown in the cultivator's way, he will prefer to resort to the money-lender for any of his requirements, although in the end it may cost him far more. I read only recently in the *Times* that no less than 10 lakhs of rupees (say £65,000) had been advanced in the Kurnool, Bellary, Anantapur, and Cuddapah districts for the purpose of well-digging alone. This but shows what room previously existed for the extension of well irrigation. In the prompt repair of tanks and other reservoirs an improvement can also be effected. But beyond these points there is evidence of the necessity of a closer study than has yet been made of the requirements of each district in respect of the provision of water supply, and of the way in which that may most suitably be carried out.

Manure.—Inseparable from, and nearly as important an agricultural need as the last one, is the supply of manure to the land. Indeed, from its having had far less attention given to it than the provision of water, it should now have particular prominence, for practically nothing has been done to increase its supply. Again, water and manure are practically interdependent. Without water, either in the rainfall or supplied by irrigation, manure is useless; without manure, water will wash out and gradually impoverish the soil, so that its fertility can only be restored by manure. It is but necessary to mention the sugar-cane cultivation around Poona, or the market-gardening of Meerut, Amritsar, Hoshiarpur, and other places, to exemplify this. In India, as in England, the crop-yields go up and down, according to the amount of manure available for application; and, if India is to produce the extra bushel or two per acre which Sir James Caird estimated it must do in order to supply the wants of an increasing population, it is very certain that it cannot be done without increasing the manure supply to the land. It is manure alone which can replace the soil constituents carried off in the crops, and to a considerable extent exported to other countries. When we come to consider the available sources of manure in India, we find them extremely meagre, and still more reduced by the poverty of the cultivator, which prevents his using to the best advantage even what he has. The universal manure the cultivator has is the solid droppings of his cattle, and the value of this he fully appreciates, but complains that he has not enough of it. The scarcity of fuel obliges him to burn the greater part of what should rightly be put on his field, to restore the fertility removed from it in the crops grown. When pondering over the question of agricultural improvement, I have often witnessed with regret the long lines of women carrying in baskets on their heads into the towns the dried cow-dung cakes, or *bratties*, that are to be used for burning as fuel. I have carefully examined the statements that have gained currency, to the effect that the dung of Indian cattle is poor in quality, and that even if burnt it loses little or nothing of value, as the ashes find their way to the field again, and the nitrogen lost in the burning comes down again in the rain, which, on that account, is richer in compounds of nitrogen than is the case in temperate climes. But the latter assertion is unsupported, for the analyses upon which it was based have since been shown to have been incorrect, and that Indian cattle manure is not poor I can prove from my own analyses. My results show that for every ton of manure burnt no less than 29¼ lbs. of nitrogen out of a total of 30 lbs., or 97·5 per cent., are entirely lost. Nor is this all the loss sustained, for the organic or vegetable matter is also destroyed, and it is in this and in nitrogen that I find Indian soils are mostly deficient, while the mechanical advantages of farmyard manure and its moisture-holding properties are lost also. The saving of the cattle manure, as far as possible, for use on the land, is, to my mind, of paramount importance. It has been said that the cultivator will always burn *bratties* for fuel, but, thought his is a general rule, I have found that among cultivators pure and simple it is not an universal rule, and that though it has become a practice, it has become so, mainly because of the absence of wood or other sources of fuel. Away from the towns, manure is hardly a purchasable material, and I have been in several parts where all of it is saved for the fields; here the cultivation has been of the best. Great improvement is possible, however, in the method of preserving manure, and chiefly in the saving of the urine, which is universally allowed to go to waste. Were but leaves, stalks, straw, or other forms of litter used, the available manure

supply might be largely increased. The next way in which an improvement might be effected is by the utilisation of night-soil, house-sweepings, &c. Prejudice is, undoubtedly, a great hindrance, but the instances which Poona, Amritsar, Meerut, Farukhabad, Cawnpore, Nagpur, &c., afford of what can be achieved when it is overcome, leave no room for doubting that great possibilities of agricultural improvement exist in the utilisation of such waste materials. A few weeks ago a paper was read in this room on the subject of sanitation in India, and I cannot help expressing the hope that, in any schemes which are brought forward in future, the importance of the agricultural side of the question will not be lost sight of. Many kinds of oil-seed are pressed for the sake of their oil, but the refuse-cake is frequently exported, and not used in the country to any extent, while folding of cattle on land, and green-manuring are only practised to a limited degree. Bones are exported from India because of the prejudices that exist against their collection and use, and because of the difficulty of preparing them for application to the land, but largely also because of there being merchants able and willing to give more for them for export purposes than the people of the country value them at. For the use of artificial manures I think there is not the least hope, so far as the ordinary cultivator is concerned, and principally on account of his want of capital. The greatest importance attaches accordingly to the utilisation of those materials which every cultivator has at hand, and which will not become the subject of export.

Wood.—The next agricultural need is the supply of wood. Only too late has it come to be realised that in denuding the country of its wood and forest land, in order to make room for cultivation, an injury has been done to agriculture which it is impossible now to remedy entirely, while even in so far as a partial amelioration can be effected, its progress must be slow and difficult. Leaving aside for the present the importance of a supply of timber, I would revert to what I pointed out in the last section, viz., the impoverishment of the soil consequent on the burning of the cattle manure which should find its way back to the land. This wasteful practice is the direct result of the clearing of the former wood and forest land, and it will continue until the cultivators can be provided with wood to serve them as fuel. Thus the creation of supplies of wood is a way in which one of the principal agricultural needs of India may be met. The Forest Department, though originally concerned with the preservation of the more distant timber forests, and having no agricultural object in view, has in later times come to see that as cultivation has spread, the wooded tracts should be made to serve more nearly the interests of agriculture as well, and that the reservation of areas and the creation of fresh ones in the midst of cultivation, is a legitimate and desirable part of its work. I go so far indeed as to regard the supply of wood for replacing dung as fuel as the one practical measure from which the greatest benefits to agriculture will accrue, and I think that sufficient importance has not been given in the past to the close connection of the provision of wood with the maintenance of the fertility of the soil. Mr. R. H. Elliot, of Kelso, was one of the earliest to draw attention to the importance of this connection, and in his paper read in 1875 before this Society, he urged the necessity of having "fuel reserves" for India. A supply of wood to serve as fuel means the liberation of manure for the land, the growing of larger crops, the supply of more fodder, the maintenance of better cattle, and in turn more manure again for the land, while to the State itself an increased revenue would accrue consequent on the higher cultivation. The growing of trees would also provide a large amount of leaves which might be usefully employed as litter, and thus save the urine of the cattle from being wasted. Nor must, finally, the beneficial influences upon climate be omitted, though to these I have already alluded. It is very certain that the existing "reserved forests" would not be sufficient or even be suitably placed to provide for the agricultural requirements of the people in the matter of wood and fuel supply, and there are many districts, notably in the North-West Provinces, where trees, and (much more) forests are nearly unknown. The difficulty is, that where wood is most wanted, there land is most taken up by cultivation, and that where it grows freely, there is no cultivation to require it urgently. Nevertheless, even in the North-West Provinces it has been shown there are considerable areas of ravine land available which might be turned into "fuel reserves," and that even on the vast salty or *usar* plains, the growing of trees and grass may be accomplished. In Madras, the waste land all belongs to Government, and here, upon the banks of rivers and channels, as well as on tank beds, trees might be grown. In Ajmere-Merwara, it

has been shown that mere protection and exclusion of grazing for a time, aided by planting here and there, will soon clothe even seemingly barren hills with trees and shrubs. Plantations of trees have also been created in many parts along canal banks and railway lines. The result of inquiries made has been to show that considerable areas are still available for tree-growing purposes, but where these are not sufficient, the only plan is to acquire land for the purpose. The financial prospects of such a scheme may not appear at first sight favourable, but there is more to be considered than the actual money returns from the sale of fuel as fodder. Practically, as I have said, it is the well-being of the people, and the keeping up of the soil, and hence, of the land revenue to the State, which are concerned, and these cannot be measured by the direct financial return alone.

Grass.—The provision of grazing, and of grass for cutting as food, is another agricultural need, though, to my mind, not of equal importance with the supply of wood. The establishment of "wood reserves," however, would imply the growth of a certain amount of grass, which could be cut and used as fodder, even it it were undesirable to permit grazing to be carried on. The most distant forests include large pasturage areas of much value, to which breeders of cattle and graziers resort, and the retention of these areas for such purposes is most desirable.

Although the cultivator may send out his better cattle, under the charge of herdsmen, to these grazing areas during the hot season, they do not supply all his needs, and something nearer at hand is wanted. It is the provision of grazing in "reserved forests" that the cultivator seeks to have, and it is this which has, in times of drought, already done great service in keeping the cattle of the country alive. It has been rightly pointed out that the growing of fodder crops would not efficiently replace grazing, for, in times of drought the fodder crops would probably fail as well. If grazing areas can be made in "reserved forests," the benefits to agriculture will be great, more especially in exceptional times; nevertheless, I cannot regard it as more than a desirable end for forests to serve in ordinary times, but not as an absolute necessity. Therefore, while utilising "reserves" in this way, wherever it can be done, grazing should be carried on only when the general utility of the "reserve" as a wood or fuel-producing area can permit of it. Thus, while natural reproduction is going on, the admission of grazing is out of the question; similarly, the number of cattle admitted must be restricted, the seasons at which they are let in must be limited also, while goats are so destructive as to have no place in a forest, except it be on an area set apart for them. The necessity of having stringent rules as to forest fires, and of preventing the setting on fire of the dry grass in order to get a fresh growth, is abundantly justified. Wherever in a "reserve" it is possible to admit cattle to certain blocks at a time, a useful end will be served; but unrestricted grazing will ruin any "reserve." At early establishment of a "reserve" it will be necessary to exclude grazing altogether, and, as a rule, I should be in favour of cutting and removing grass in ordinary times, rather than of feeding it down by stock; in exceptional times of drought, however, the "reserves" should be thrown open. The village grazing - ground, or "waste," is a useless institution, so far as grazing is concerned, and it serves no purpose but to provide standing and exercise room for herds of half-starved cattle. These village wastes are lamentable examples of what unrestricted grazing will do, and they may be productive of positive harm as affording a ready means of spreading disease should it break out. The best thing that could be done would be to enclose the wastes and restrict the grazing on them; but it is a difficult matter to interfere with the villagers' inherited privileges.

It has been suggested that the growing of grass by the cultivator upon his holding should form a part of his farming system, but this could hardly be done without irrigation, and as the first object of the *raiyat* is to grow crops that provide him with food, and his cattle with fodder, he is hardly likely, I think, to set land apart for pasture purposes alone. It has been said also, that India will be the great field for the development of ensilage. This I cannot think to be the case, although here and there, as on military *rukhs* and grass farms, it may be usefully employed. When hay cannot be made, grass may be saved as silage, but the conditions of India are far more favourable to the making of hay than of silage.

Fodder-crops.—The growing of special fodder-crops may, in one way, be termed an agricultural need, for though, like grazing, not an absolute necessity for the existence of cattle, it is, nevertheless, necessary for their improvement. The superiority

of the cattle of the Punjab is largely due to the practice of growing fodder-crops, and the same is seen when comparing the cattle of the European planters in Behar with those of the native cultivators. There are also many materials, such as hedge-clippings, prickly-pear, pods of the *babul* (acacia) tree, and shoots and leaves of other trees which might be more used as fodder. In this connection, the advantage of enclosing fields with hedges, and of penning cattle on the land, might be mentioned.

Cattle.—In the rearing of stock there is not much to be learnt from the native cultivator. Here and there, fine cattle are bred, and special strains are kept up ; but, as regards the ordinary cultivator, there is hardly any attention whatever paid to the breeding or selection of cattle. The sacred or Brahmini bull, who roams at will over fields and through villages, is in many parts becoming extinct, and the breeding of stock is left greatly to chance. There is little doubt that by providing good stud-bulls the cattle of the country might be greatly improved. This is work which Government has for some time carried on at farms, such as the Hissar Cattle Farm in the Punjab, the Amrit Mahal Farm in Mysore, and more recently at Bhadgaon in Bombay. The fine cattle of the Punjab owe their present excellence largely to the bulls sent out from Hissar. It would be a great good to the country were this system extended to other parts, and bulls to be distributed to villages, there to be placed under the charge of the village headman, who in turn should be required to report to the local authority. There is plenty of good material to be found in India, if only selection were made, and there is no occasion or advantage to be gained from going beyond India. The location of stud-bulls at Government farms, and on Court of Wards' estates, would benefit the cattle of the district, and, though the result might not be a directly paying one, the step is one which might well be taken in the interests of the agricultural classes.

As a milking animal, the buffalo is more valued than the cow, and is generally well looked after by the native, so that here there is no call for improvement.

Attempts have recently been made to improve Indian dairy methods, but I am not inclined to think that English methods will take the place of native ones in any parts except large towns, and where there are European residents. The native butter, called *ghi*, is hardly likely to be replaced by butter as known to us in England, for the simple reason that the latter will not keep as *ghi* does. But what there is decided need for, is, to remedy the existing conditions of the milk supply, more especially to troops and to Government institutions. At present the surroundings are almost always of an insanitary nature, and neither control nor inspection is exercised over them. Where troops are regularly quartered, dairy farms might, with great advantage, be established.

Yet another need arises in connection with cattle, the gaining of more information with regard to the diseases of cattle, and the means of curing them, as also the prevention of the spread of epidemics. Of late, a decided step has been taken in this direction, by the establishment of a bacteriological laboratory at Poona, and a similar move is in contemplation at Lahore. The enormous losses that take place through cattle disease, and the stoppage of agricultural operations in consequence, demand that serious attention be given to the investigation of these evils and their means of cure.

Implements.—It is only in a very limited sense that I am prepared to consider better implements as an agricultural need of India. Until an iron plough can be produced which does not cost more than the native wooden one, and which can be repaired in the cultivator's village, I do not think it is likely to replace the present plough, nor am I convinced that, on the whole, the change would be an advantage under the present conditions of Indian agriculture. Similarly, there is little scope for the introduction of sowing, reaping, or threshing-machines. In appliances for raising water, the native has shown himself an adept, and there is nothing we can teach him in this. The one instance in which a great success has followed the introduction of an implement new to the Indian cultivator, is that of the iron mill for pressing the sugar-canes. After several years of patient study of native requirements, Messrs. Thomson and Mylne, of Beheea, brought out a portable sugar-mill which exactly suited the cultivator, and was far superior to any of the native implements. The consequence was the ready adoption of the new mill, and the replacement of the old ones. Similar, but more limited benefit may result from the introduction of shallow evaporating pans for sugar-boiling, instead of the deep ones often used. But in every case where an introduction is to meet with success, it will, I am sure, only be as the outcome of

careful study of native conditions and requirements.

Cultivation.—I have, at the outset, expressed my opinion that the improvement of cultivation is, in the main, not an agricultural need in India. In brief, there is little that may not be remedied from India itself. Still, there are one or two "needs" in regard to cultivation that I may just touch upon. Though the cultivator understands the advantages of rotation, and would practise fallowing if he could afford to, he does not appreciate the advantage of selection and change of seed. That this is so, arises largely from the practice of resorting to the grain-merchant, who is also the money-lender, in order to obtain an advance of seed for the crop that is to be grown. He is therefore dependent upon what the money-lender supplies. Thus it becomes impossible to preserve pure varieties of cotton or other crops, for the seed is brought in in small lots, mixed together, and then sold again. It becomes, therefore, one of the most useful purposes which Government farms may serve, to grow pure seed and to have it available for distribution to the cultivators. In this way the Cawnpore farm of the North-West Government has already done very useful work, and the extension of seed-farms to serve as centres for the distribution of good seed is to be much commended. A certain amount of advantage may be derived from the introduction of new crops and new varieties of crops, and the history of millet, maize, tobacco, tea, coffee, potato, &c., tells of the success attending the importation of new crops. But the main benefits will be experienced in the transference of methods of cultivation from one part of India to another. Even in rice-growing, but still more in sugar cultivation, there are methods practised in one part which are superior to those adopted in another, and if, as the result of careful inquiry into existing practice, this transference can be accomplished, the result will be a general bettering of the cultivation. It is very certain that both the cultivation and the out-turn of sugar in India could be very considerably increased, and that India ought in this matter to be rather an exporting than an importing country. There is comparatively little known about the circumstances which affect the yield of sugar, and the manufacture would be much improved were more cleanliness employed. The curing of tobacco is carried on in a very crude way, although the cultivation is of the most careful kind.

I have now given in brief review the principal agricultural needs of India as they impressed themselves upon me during my inquiry. In the course of my remarks, I have had occasion to refer, in passing, to other needs than those specifically named, such as the necessity of inquiry, both of a practical and of a scientific kind, as also to the need of spreading education. It is impossible in a paper like the present to deal with all these large subjects, and, as they are to form part of a forthcoming report, I have considered it better to confine myself on this occasion to matters of a more strictly practical nature. There are also, as I said in my opening remarks, great questions affecting the prosperity of agriculture, which are concerned mainly with the relations of the State to the people, and of landlords to tenants, as well as others inseparable from a consideration of the social habits of the people, their ways of living, &c. These questions all require for their proper treatment a far wider experience of the people and of the country than I have been able, with my limited opportunities, to gain; and, for this reason, I have not attempted to deal with them.

DISCUSSION.

General J. MICHAEL, C.S.I., said Dr. Voelcker had touched upon a very important point, in saying that India's most urgent need, next to water, was manure. They all knew how the ryot, for want of fuel, was obliged to burn the manure, which he would only too gladly put on the land; and there was here room for further aid by the Forest Department. During the last half century that department had succeeded and developed to such a marvellous extent, and so far beyond all expectation that, after paying all its own expenses, it now yielded a revenue of over half a million sterling. Having that large revenue, it could afford to do more than it had towards providing free fuel reserves for the villager, so as to enable him to utilise his cattle manure instead of burning it. The Chairman had been good enough to allude to him as the pioneer of practical forestry in India, and he well remembered when the forest operations commenced in Southern India, the Madras Government wisely laid down the dictum that the preservation of natural resources in the forests, which included fuel, should be the first consideration, and the acquisition of revenue the second. That principle had been to a great extent maintained, but it might be extended, and a larger area of fuel reserves provided. By so doing, it would be lending money to the soil, which would be repaid by increasing prosperity in the future.

Sir C. E. BERNARD, K.C.S.I., said it was very satisfactory to find that Dr. Voelcker, after careful in-

quiry, had come to the conclusion that Indian agriculture could only be improved on Indian lines, and that he recognised the fact that India consisted of many countries, climates, and kinds of agriculture, so that any one system of improvement could not apply to the whole country. He had also found that in some parts the agriculture was already of a very high character, and that a reformer should make it his object to apply locally—as they were suitable—the best plans already used in other parts. What India wanted most was manure and water—manure first—and, as General Michael said, the Forest Department was doing what it could to make fuel available. In some parts of the country cattle droppings could be little spared for the manure, but in Burma, where there was plenty of fuel, it all went on to the land. In some parts of India—in the great delta of the Ganges, for instance, and in the north of India—there was not much chance of growing forests, but there was another source of fuel, namely, the coal-fields, which might hereafter be made generally available, so that the cultivator might have the manure available to put on the land. In some parts, water was the great need, but, in other parts, the difficulty was to keep the water off the land. In the Godavery delta, water was a great blessing; but in some parts. such for instance as the black soil country of Kurnool and Cuddapah, there was a great difficulty in getting the people to take canal water. It was very true that more agricultural teaching education was required, and it should be not primarily to the cultivator, but to the village schoolmaster. Dr. Voelcker had quoted, with approval, Sir James Caird's dictum, that a great want in India was to get an additional bushel per acre off the land. At the Cawnpore farm, last year, on 30 plots, the average yield was from 33 to 43 bushels per acre, and the largest yield gave a money profit of 87 rupees per acre. Of course, that was good land, well irrigated and manured, near Cawnpore. The manure was not foreign manure, but that available on the spot—indigo refuse and lime. The great problem for the Government of India was the enormous population, which was increasing at the rate of 70,000,000 in a generation, and how that population was to be fed. Certainly that increase of population, which was quite unknown in former times, was a great credit to the Queen's Government, and was in some degree an answer to the pessimists, who say that India is being ground down and her people are perishing under foreign and alien rule. But although this was, in one sense, a cause for satisfaction, it was a source of great difficulty. He hoped that Dr. Voelcker's forthcoming report would form a valuable step in the agricultural progress which must take place in India if that country had to support such an enormous population.

Lord Reay said he agreed with most of the conclusions put forward in the paper. With regard to education, he might say that while he was in Bombay they obtained from the University a diploma in agriculture, intended mainly for those who had been through the agricultural course of the College of Science in Poona, which the indefatigable efforts of his friend, Dr. Cooke, had raised to a high state of efficiency, and it was a great disappointment to him that he could only obtain a diploma, not a degree in agriculture such, as was given at Edinburgh, from the Bombay University. He agreed with what had been said about the importance of schoolmasters being taught agriculture, but there was another class to whom it would be of the highest importance, and that was the native official who lived in the rural districts, and who was constantly in touch with the people, to whom he would thus be able to show how to make the best use of what he had been taught. The Government of Bombay had carefully considered the possibility of including in the examination of such officials the precepts and practice of agriculture. The want of a knowledge of agricultural chemistry was also felt by the Bombay Government, which had tried to obtain from the Government of India the appointment of an agricultural chemist for the whole of India, to be paid by contributions from the various provinces, but he was afraid no effect had as yet been given to the proposal. He was happy to say that the Bombay Forest Department thoroughly realised the importance of supplying timber for fuel; with due attention to working plans and regular cuttings, as well as settlements and careful supervision of grazing areas, the people wonld gradually realise the benefits of conservancy. He did not quite agree with a previous speaker that the department did not care about increasing the revenue. In Bombay, the conservators certainly wanted to have a good surplus, but this was compatible with the supply of fuel. Another point of great importance was the Veterinary Department. In Bombay, the veterinary school had been placed on a better foundation, and the results were most satisfactory. Horse breeding also was a matter of great importance, from an agricultural as well as from a military point of view; and a great deal could be done in that regard in the native States. In Kattyawar the native chiefs had taken it up, and perhaps no class in India could do more to prevail on their countrymen to adopt improved methods of breeding and of tillage of the soil than the native chiefs. The Gaekwar of Baroda was fully aware of this, and in his College at Baroda had appointed a Professor of Agriculture. Another means of promoting agricultural improvements was not to raise the assessment on the land too suddenly or too rapidly, and this also was borne in mind in the Bombay Presidency. The late Mr. Theodore Stewart, one of the best Survey and Settlement Commissioners they ever had, always tried to increase the assessments cautiously, so that the cultivators should have a sufficient margin to improve their holdings, and he considered that the indirect benefits which would accrue from such a wise procedure

would be infinitely greater than any additional revenue which could be obtained by a process of rack-renting. On the relations of the money-lender to the agriculturist he would not dwell, as a Commission was inquiring how they affected a ryot. Any prejudice which might have existed in the Brahmin caste against agriculture had given way in the Bombay Presidency, for Brahmins were now investing in land. This would naturally tend to alter the tenure of land, and might bring about what Sir James Caird desired to see—a system of larger holdings instead of the small "number" hitherto the distinguishing feature of the Bombay tenure. With regard to irrigation there was a great difficulty. His experience in Bombay, excluding Sind, was that agriculturists only took the water at the last moment, under pressure of extreme drought, and, therefore, in years when the rainfall was scanty, but not wholly insufficient, the canals would not pay. The receipts, therefore, were irregular, but in Deccan, where the rainfall was uncertain, the irrigation water was certainly needed to supply a deficiency, and he thought it well repaid the cost of the good work the Irrigation Department was doing, as it gave the occupant a sense of security which otherwise he could not feel. He was glad to say that the experience gained in India was now made available in Egypt, where he had recently seen with pleasure the excellent results obtained by Colonel Sir Scott Moncrieff and other Indian Engineers—results thoroughly appreciated by the fellaheen who depended on water for their crops.

Sir Steuart Colvin Bayley, K.C.S.I., said much which he might have said had already been put to the meeting by previous speakers. Dr. Voelcker had wisely abstained from discussing administrative or revenue questions, and had described the practical needs and suggested practical remedies, namely, irrigation and afforestation, the improvement and increasing of manure, and improved cattle-breeding and doctoring. If none of these remedies were new to those who had taken an interest in the matter, it did not at all detract from the soundness of the advice. There was one remark, however, to which he might take some exception. He spoke of the canals not being always placed where they were wanted, and about the injury they undoubtedly caused, and, amongst others, he mentioned the canals in Behar. They had not been a financial success, but he could not admit they were not wanted. They were wanted there, and had done incalculable benefit, for they had saved lives and money in the way of revenue, which far more than repaid, in an indirect way, their original cost. They had, however, materially changed the cultivation in the district of Charterabad. The land formerly only grew *rabi* crops, but the result of giving water freely had been that rice had supplanted *rabi* to a large extent, to the pecuniary profit of the cultivator, but also to his physical detriment, because the district, which was a remarkably healthy one, was now feverish and unhealthy. The remarks with regard to the difference between lift and flow irrigation had a very important bearing. It was not an advantage to the cultivator to get water too cheap or too easily, or too much of it. With regard to the question of manure they were greatly indebted to the reader of the paper for effectually destroying the pestilent heresy that the ash of burnt cow-dung was as beneficial to the land as the unburnt manure. Some newspapers in India had taken up the cry, and it would have kept the cultivator in a fool's paradise. Irrigation and manure ought to go together. Irrigation without manure did harm after a certain term of years. Artificial manures were impossible to the native ryot at present; and, therefore, if the supply was to be increased, it must be by supplementing their fuel reserves. On that general principle all would be agreed, but when it came to working the thing out in practice there would probably be differences of opinion, and he did not see how it was to be done. The Forest Department was a highly organised department with expensive experts. They were quite in their place in dealing with large areas of forest reserves, mostly in the sparsely-populated districts, where they came into contact with outlying tribes, whose agricultural methods were of a very low type, and whose real interests were by no means always the same as their immediate demands. But if we want fuel reserves to be of any use at all, they must be brought almost to the villagers' door, and where the population was thickest all the land was already used for food crops, and it was not very easy to see how land was to be taken up and planted, and machinery provided for distributing fuel and arranging for its reproduction. In Bengal the officials were not in touch directly with the agriculture of the country, but in other provinces, where village communities still remained, and Government officials were in direct touch with the people, there might be some means of coping with the difficulty. It was quite true, as Dr. Voelcker said, that the Government could not go in for a large system of well-digging, but should pursue the system of *toccavi* advances for well-making; but the success or otherwise of this method depended very much on the interest and personal character of the collector. He knew an officer in the Bengal Opium Department who had been at Sawan for twenty years, and took great interest in the question of well irrigation. He persuaded the opium agents to make advances for wells to the cultivators, and the whole of his division was thoroughly protected against drought as far as any country could be by that means. Too much attention could not be paid to improved cattle breeding. In some parts of India—in Bengal and Assam, for instance—nothing could be worse. He believed the agricultural community kept far more cattle than was necessary, or than they could afford to feed. If they had half the number, properly fed and housed, and systematically bred and doctored, they would be far better off.

He hoped that Dr. Voelcker's mission would be fruitful in benefiting India, and that, before long, India would have the advantage of the advice of a permanent agricultural chemist.

Professor WALLACE said this paper was thoroughly orthodox, in fact, his principal complaint was that it was too orthodox. It was unnecessary for him to follow other speakers in saying how much he agreed with Dr. Voelcker, he would rather criticise, and say the worst he could about it. It was not so much what Dr. Voelcker had said himself, as the quotation he had made from Mr. Elliott, which he objected to. Mr. Elliott said that if he could put nine-tenths of the inhabitants to the sword, and divide the best of the country into 200 acre farms, and so on, he could easily put Indian agriculture on a satisfactory footing. But how were all these farms to be cultivated if the inhabitants, or a greater part of them, were got rid of? Dr. Voelcker said he did not believe in the introduction of English systems, but in developing Indian agriculture from within. But what was he going to do if he did away with the labourers who now worked in the fields? This would require the introduction of expensive machinery. So the quotation seemed hardly consistent with his own notions. Mr. Elliott also referred to destroying the whole social system of the Hindoos, teaching the people to emigrate, and so on, and said that in the absence of such a possibility it was impossible to do more than produce by slow and painful steps some amelioration of the existing state of things. Dr. Voelcker said those were in the main the views he had formed, but then he went on to show that he did not quite agree with all this, because in some parts the cultivation was excellent. How did that come about? It was not so at the beginning. The Indian cultivator had shown himself capable of carrying out improvements in his methods of cultivation; and, again, no less than ten lacs of rupees had been spent in one district to develop irrigation. The Behea sugar mill had been introduced; and the Brahmins had taken to agricultural operations. He had travelled with a Brahmin from Bombay up to the northern part of India, and he must say that that Brahmin's conduct and conversation opened his eyes considerably. He said he should be only too pleased if he saw openings to train up one or more of his numerous family to agriculture. It was to be regretted that Dr. Voelcker had not said anything of the most recent advance in agriculture in the way of supplying manure. He quite agreed that manure, together with irrigation water, was the one thing needed in India; but he totally disagreed with Dr. Voelcker that the way to get it best and cheapest was to deprive the natives of the only fuel that they had. It could be got in a cheap and ready way without depriving the people of anything they at present possessed. Within the last few days information had come from America that the great boom in the Western States was a development of the growth of clover on exhausted wheat lands. This formed the cheapest, best, and most suitable source of nitrogen, which was the most valuable of all manures for India or any other place in the universe, and it was only on account of the loss of nitrogen that the burning of manure could be condemned. The other substances were not destroyed, but, on the contrary, they were improved and made more available. Humus, unless when fresh (and the same remark applied to stale dung in the soil), was in a very insoluble condition, not at all suitable to assist the growth of plants, and when burnt to ashes it was much improved. If then nitrogen were supplied by the growth of leguminous plants, the main object would be gained. Western Americans have recently discovered that they can grow clover well, and that it can resist drought when planted two inches deeper than formerly. This is expected to add two or three bushels per acre to the produce of wheat. Some simple thing like that might do a great deal for the development and increase of the average production in India. In fact they were simply on the threshold of agricultural experiments. He rather demurred also to the statement with regard to silage. He asserted that good hay could not be made in India at the season when grass was most plentiful. Silage had its place, and it was an extremely valuable and important addition to food, especially in countries liable to severe droughts. With regard to *usar*, drainage and washing was the only cure. He had seen it in nearly every quarter of the globe; and if you only supplied a sufficient amount of water, and provided means for its escape, *usar* would disappear naturally. He could not sit down without saying one word in support of the idea that Indian implements were, in the main, good for the sort of cultivation they had to perform. This was not a new idea to him, for he was immensely interested, some years ago, in an article by Sir George Birdwood on the Mahratta plough; and it seemed to him that, by showing our appreciation of what was good in native practices, we should make the natives think more of themselves, and they would also be more inclined to take advice from us when it was offered.

Mr. THISELTON-DYER, C.M.G., F.R.S., said the statistical tables published by the Board of Agriculture showed that the produce of wheat in India was about nine bushels to the acre; in Scotland, it was about 36 bushels; in England, about 30; and in the Western States of America about ten. Wheat production in India, therefore, and the United States, was about the same, and that meant that the fertility of India and of the great corn-producing districts in the States, had come down to what might be called the mean natural fertility, or that condition which the soil ultimately arrived at when you went on cultivating and did not add any manure. There was no reason to suppose that the soil of India would become any less fertile

than that. And it was far from having lost the recuperative power of grain-cultivated soil. They had been told that it was possible in India to get 48 bushels an acre, which was far above what was done by the careful agriculture of Scotland. There was, therefore, no doubt that results could be obtained far beyond the modest demand which Sir James Caird made. But there was a further fact that in the past generation population had increased by 70,000,000, and so one came back to the question, what was to be done to produce from the soil sufficient food to keep up such a population. Of course, it would not go on at that rate, because the ordinary Malthusian principles would come into work sooner or later, and the contrast between the fertility of the soil and of the people would diminish. During the last twenty years, he had been consulted more than once by the Secretary of State on this question, for although he had never been in India, he had given a great deal of attention to official documents bearing on it, and it was perfectly clear that the real question was, how to get more nitrogen into the soil. That point overshadowed everything else. He had anticipated the difficulty Sir Steuart Bayley raised, in the substitution of wood for manure as fuel, but he could not see how stopping burning manure would give a sufficient supply of nitrogen to produce the results desired. Professor Wallace had indicated one way, and about that there could be no doubt theoretically. After the studies made in Germany, France, and England, there could be no longer any doubt that the growing of leguminous crops did enrich the soil with nitrogen in a way which, as far as was at present known, without manure, could be done in no other way; but in India the method of green soiling was not altogether unknown. If it were, the sooner some popular account of the method was distributed the better. An old pupil of his own, who had charge for a time of an experimental farm at Bangalore, found that by making some slight addition to the Indian plough he was able to stir the soil—not to plough deeply, but to stir it lower than the ordinary plough did, and, by slightly opening the subsoil in this way, the roots were able to get down lower, and the crops, even in a season of drought, flourished in a way they did not when the soil was cultivated in the ordinary manner. He was inclined to think that the Indian plough was a thing which deserved a good deal of study; but it could not be studied very well by people in Europe, because our conditions were so different. The study should be made on the spot, and efforts should be made to improve the agricultural methods there by the introduction, if possible, of some kind of rotation with leguminous crops. He was under the impression that, in a great deal of the cultivated land of India, there was something like a pan, formed at no great distance below the surface, which made it extremely difficult for the roots to penetrate, and so they were unable to bear even a slight drought.

Brigade-Surgeon PRINGLE said that too much irrigation water was infinitely worse than too little, because, while next year corrected the errors of the last, it often took years to remove those of the first. The question of cattle supply was a very serious one; and if he were asked to name the greatest obstacle to the spread of cultivation, and how to remove it, he should say, supply cheap bullocks. The class of animals now used in the North-West Provinces was too often really unfit for work; and, as a sanitary officer, he stated that his inspection of slaughter-houses clearly proved that the mode of selecting the animals to supply the beef for British troops was most objectionable, and that, coupled with the total absence of veterinary treatment, this was, in his opinion, the chief cause of the great rise in the price of bullocks, and that unless some steps were taken to check this, the obstacle of cheap bullocks would go on increasing. The quality of the seed grain was also an important question. The cultivator had too often to take any seed which the money-lender chose to give him, for the interest wanted was too high to lend the ryot money, and the advance was repaid in quantity more than in quality. One thing Dr. Voelcker had not alluded to, viz., the reason of the very small quantity of straw available for manure, which was due to the custom of burning down often the long stubble on the ground; but he had no hesitation in saying that in this way, unknowingly, they got rid of an enormous amount of most pernicious larvæ, and this was the reason why Indian agriculture, where this was practised, was not visited with the pests, which were found in so many other countries. If there was a hard-worked agriculturist in the world, it was the Indian ryot.

Mr. W. S. SETON-KARR said that some statements in the paper would not apply to Bengal, the Province with which he was best acquainted, except with a little qualification. The two main points no doubt were manure and water. As Sir William Hunter had shown, in many places it was the poverty and not the ignorance of the ryot which prevented him from using manure. With regard to the principal rice crop of Central Bengal, manure was not needed, as the rainfall brought down silt from the higher lands, and the Ganges and its distributaries also brought down an enormous quantity of silt. In Western Bengal the ryots stored water on the tops of the hills in reservoirs, and let the water flow down into the plain below. He had observed, with much regret that, in that part of Bengal, a great deal of land, formerly covered with jungle and forest, had been cleared, but it was not turned up by the plough, so that it was neither one thing nor the other. The scrub remained, but there was not energy enough to convert the ground into arable land. He might add that, with regard to estates brought under the Court of Wards, it was provided that portions of the forest should be reserved. Dr. Voelcker was no doubt judicious in

not entering into the vexed question of land tenures, as they affected the agriculture of India. But he could not sit down without some reference to those agriculturists by whom, with unscientific instruments, the magnificent results alluded to in the paper had been mainly achieved; they were the Jâts of upper India, the cultivating communities, and the tenant-proprietors of Bengal. These men reminded him of that ancient cultivator whom the great Roman poet had seen in Southern Italy, and whom he had described in his own picturesque language as one

> "Cui paaua relicti
> Jugera ruris erant; nec fertilis illa juvencis
> Nec pecori opportuna seges, nec commoda Baccho."

And then he goes on to say that this old man, sowing vegetables, white lilies, vervain, and the edible poppy, was quite as happy as a king—

> "Regum æquabat opes animis serâque revertens
> Nocte domum, dapibus mensas onerabat inemptis."

Dr. G. WATT, C.I.E., quite agreed with Dr. Voelcker that the agriculture of India should be developed from within instead of from without. He had been working at the literature of Indian agriculture, in compiling a dictionary which he was engaged upon, and that one idea he found ran through everything he had to deal with. The contrary system had been tried in every way. In the importation of new crops and improved breeds of cattle and sheep, everything had been tried, and nothing had been left undone except the most important of all, that of making an effort to improve what already existed in the country. It was of no use to import pedigree animals if no effort were made to improve the indigenous stock upon which they were to operate. Whole herds of every kind of sheep, for example, had been imported, and on one occasion the Bombay Government procured several hundred Merino rams and ewes; but not a trace remained of those experiments. And this was entirely the result of no preparation having been made in India to improve the native breed before importing the foreign element. It was the same thing with sugar. More than a century ago the Government was asked to assign land to farmers for the cultivation of sugar upon European principles. This was acceded to, and plantations were opened out in which high-class canes were grown. Shortly afterwards the undertaking was reported a failure. Later on the same proposal was made, and the same effort put forth, and for twenty to thirty years the *Journal of the Agricultural Society of India* may be said to have been filled almost exclusively with reports on sugar-cane cultivation; the only trace that now remains of the plantations and factories are the ruins of the buildings. After a few years, the whole of the imported canes died from disease, whilst alongside of the experimental farms there were indigenous canes of as high a quality as any which could be imported. Only the other day a gentleman came from Java, for the sole purpose of taking Indian canes to that island for cultivation. The same thing had happened with tea. No one was satisfied with the fact that there was tea in India, and thousands of pounds were spent in bringing the tea plant from China. This was done; but in Assam, at least, the China tea is now regarded as the curse of the country. The indigenous plant has been found to be far superior. It was just the same thing with indigo. The industry migrated from Bengal and came back again. The native method of manufacture is actually based on much more scientific principles than the European, though the planters are too self-satisfied to learn from the experience gained from centuries. With cotton, the spirit of importation of foreign stock had proved even more disastrous than with sugar-cane; for the imported stock had not only degenerated, but had lowered the value of the Indian races of that crop. We require, therefore, less foreign importation, and more local knowledge, if we seek to actually improve the agriculture of India. The gains, through imported crops and breeds of animals, do not compensate for the total want of the principle of "self-help."

The CHAIRMAN said the time was now exhausted, but any gentleman who had sent up his name might have an opportunity of putting his remarks in writing. This was a subject in which he had taken great interest himself, and he should be very glad to say something about it, but it was now too late; and he could only conclude by proposing a vote of thanks to Dr. Voelcker. He was sure the report he was about to submit to the Government of India would be of the highest value, showing what they ought to do, and also what they ought to avoid.

The vote of thanks having been carried unanimously,

Dr. VOELCKER, in reply, said it afforded him great satisfaction that his paper had been the means of eliciting so valuable a discussion. The differences of opinion which had been expressed were due, in great measure, to the diversities in the conditions of India. One speaker would refer to a part where the country never suffered from any want of water, whilst another had had more to do with a district where it was the great deficiency. So what was said in the paper was evidently correct, that what would suit one part of the country would not do for another; and this constituted the difficulty that anyone like himself would have in coming to any general conclusion as to how to improve Indian agriculture. If he had erred somewhat on the line of caution, it was, on the whole, the safest side to err upon. It was a great satisfaction to him to know that Lord Reay had done a great deal to remove some difficulties, to which he had alluded in the opening, by means of education, and that progress was being made in Bombay. The cause of agricultural progress lost a great friend when

Lord Reay left India, and the Veterinary and other Departments, had found in him an able and earnest advocate. Sir Steuart Bayley mentioned to him, when in India, some of the difficulties to which allusion had been made. He could only say with regard to the working out of a scheme of "fuel reserves," that the difficulties in Bengal were not those to be met with in Madras, Bombay, and some other parts. To forecast somewhat, he considered the working of village forests was a matter which, while it might at first be taken up by the Government, must, in the end, be carried out by the people themselves; but after a few years of supervision they would come to understand the benefit of these "reserves," and would find their agriculture much improved thereby. He was glad to see Professor Wallace had deserted some of his old friends, and taken up new ones from America, but he was not quite so sanguine as the Professor. The practice of green-manuring had not as yet succeeded in bringing to those fields and experimental farms, on which it had been tried, the wonderful increase of crop which was to supply the extra demand of the increasing population. Without altogether binding himself by the opinion of Mr. Elliott, which he had quoted, he reminded Professor Wallace that no one could say the highest type of agriculture was that pursued when there were millions of people crowded together on the land. This was rather speaking of things as they might be, but the real question was how to deal with things as they were. With regard to silage, he was totally at variance with Professor Wallace, and the military authorities, among others, had come to the conclusion that there was a great deal of money being wasted in making silage, when the sun was—as it generally was—blazing hot, while silage was being made.

The following communications on the subject of the paper, from gentlemen who were unable to join in the discussion, have been received since the meeting:—

General Sir ARTHUR COTTON, K.C.S.I., writes:—Incomparably the greatest point in Indian land produce is water containing fertilising sediment. In Madras the difference between an acre of land of average fertility with such water or without, is either the whole crop of rice, value 40 rupees, as in a year of drought like 1877, or 30 rupees as in years when the rains have not failed. This difference is solely the effect of river-water for any length of time, without any other accessory except the ordinary present cultivation. Land in Tanjore has been thus productive for 200 years, the soil being entirely renewed by the material contained in the river water when in flood. The Godavery district was so far below all other districts in poverty, that a special Commissioner was sent to see what could be done to raise it from its extraordinary state of depression. He recommended irrigation works, which were begun by Lord Tweeddale, and now the district is (at least it was a few years ago, and I suppose is still) ahead of all the districts of India in land revenue. The expenditure has been £1,250,000, and the increase in revenue is some £400,000 a year. In the summer of 1877, when millions died in the adjoining districts, it not only lost none but saved the lives of perhaps a million outside of it. The cost was 18 rupees per acre, including embanking all the rivers, draining the whole delta, and 500 miles of steamboat canal. The river irrigation is 700,000 acres, yielding about 30 rupees more than before, or £2,000,000, and certainly increasing the income of people in all, at least £2,500,000, or 200 per cent. on the outlay in ordinary years, besides securing it from famine as at present. About 3 per cent. of the water of the ten great rivers of India has been thus led out upon the land, watering 9,000,000 acres, so that there is rich water now running to waste, sufficient to water 300,000,000 acres of rice, or 1,200,000,000 of dry grain; and not only to secure the crop by moisture, but to renew the land fully by fertilising materials. Think of this immeasurable treasure of water and manure being lost for want of engineering works. There are yet many millions of acres of alluvial land unwatered; but the upper lands might cost about double what the delta land has cost, or 40 rupees an acre; but this would yield a profit far above what almost any other investment of capital would return, independent of the saving of life. If the millions, now unemployed from want of local rains, were executing great works of irrigation in their own districts, not only would those districts be secured from famines, but the whole population would be placed in a state of prosperity. far beyond any thing now thought of. In the Punjab within the last few years the Government seem to have set themselves in earnest to this great fundamental work. Three million acres are now irrigated, and several great works are in hand. There is also one considerable work in the South of Madras under execution, but only for 100,000 acres, when it might have been so projected as to produce some five times the same results. But everywhere else in India this subject is entirely neglected, or the works have been carried out so as to ensure failure. As for instance in Orissa, where most head works have been constructed commanding some 1,500,000 acres, but the water has been only distributed to some 200,000 acres. Were the head works completed, and the whole delta provided with the works of distribution, &c., 2,000,000 acres would be irrigated with the rich river water, the whole delta would be secured by embankments from river floods, and by drainage canals from rain floods, and provided with steamboat canals, which would make the cost of transit nominal. But I may mention one essential point, which from the report kindly sent me seems to have been entirely lost sight of, of late, viz., the difference between rain and river-water. I see no mention made of this in last year's

reports. There is there a great rainfall, so that if the quality of the water is not considered, the land is in danger of being supplied entirely or almost entirely with rain water, and thus the invaluable treasure of the fertilising materials in the river water lost, after all the expenditure to divert it to the land. The fact is, that where the works are executed the great enemy to be contended with is the rain. During the falls of rain the fields should be kept as empty as possible, and the moment there is a pause in the rains the fields should be filled full of river water. If this is lost sight of, the greater part of the value of the works is lost. I see experiments made as to the comparative value of crop from land under the canals and land dependent entirely upon the local rains, and in the accounts of these nothing whatever is said on this essential point, showing that it is not thought of. The experiment wanted is to try to the uttermost to get rid of the rain water, and keep the land supplied from the canals, and thus see what the full effects of the river water are, so far as can be where the rains are so considerable. There is another part of this subject that I ought to refer to, and that is the storage of water for use in the dry season. It is remarkable that India is entirely without lakes; but, on the other hand, it is equally remarkable for natural basins, that only require narrow outlets, to be closed by embankments, in order to store enormous bodies of water, of which there is a certain amount in the lands above them. One of these is probably without parallel in the world, in the basin of the Toombudra, 1,600 feet above the level of the sea, and so commanding almost the whole Madras Presidency. And several others have been examined and reported on. In Bombay alone have the Government done anything in the way of turning to account the inviting openings. There Colonel Fyfe has constructed several, one an extraordinarily fine work, above Poona, which has a capacity of 200,000,000 cubic yards, and as it will be constantly filling for about five months in the year, while the water is being used, it may supply four or five times its capacity, or 1,000,000,000 cubic yards. The native Governments understood this matter, and there are 80,000 or 100,000 tanks in the Peninsula, but they are almost all defective in not being supplied by the south-west monsoon but only by the local rains, so that when they fail they are useless. If Colonel Fyfe's counsels had been attended to, all the great irrigation works of our Government would have been provided with those stores of water, and their canals kept full all the dry season, providing especially for the cultivation of sugar, as well as improving the river navigations immensely. Thus the Orissa works have one known reservoir of immense capacity available, and, no doubt, many more. The Sone works, also, could thus have been secured for sugar cultivation to any extent. When these two great points are thoroughly taken up by the Government, India will be such a garden as is not now thought of. I am quite satisfied that if the details of agriculture are really attended to also, the most extraordinary results will be obtained, and the produce of land as greatly increased and improved as has been the case in every other branch of human industry without exception, for this point must be kept continually in view, that agriculture alone has undergone no improvement worth mentioning, while everything else, without exception—medicine, navigation, manufacturing of all kinds, &c.—have made the most extraordinary progress.

Surgeon-Lieutenant-Colonel T. H. Hendley, C.I.E., writes:—I listened with extreme interest to Dr. Voelcker's most valuable paper, and especially to that part of it which relates to the connection of sannitation with agriculture. He will be glad to learn that that side of the question was not forgotten at the Congress of Hygiene which was held last year in London. I think Sir W. Moore had something to say on the subject, but in a paper I read in the Indian Section, amongst other relevant observations the following occurs:—"Much of the natural animal manure is lost by the conversion of it into dried cakes for fuel, owing to the scarcity of wood. The women are engaged for many hours every day in preparing it with their own hands, from which results a further evil, viz., that the poor cannot have clean food as long as their wives are compelled to follow this vile practice. A true sanitary reform is, therefore, the extension of forests with the provision of cheap fuel. Here, however, the agriculturist gives further trouble by demanding why his grazing rights are restricted, as they necessarily are by forest reservation. On every hand fresh difficulties spring up." To be of use to the villager, both for fuel and for many purposes connected with his occupations, wood must be within easy reach. Until this is the case, the villager's wife will continue to make *bratties* and defile her husband's food. Fortunately near most villages in Rajputana, *beers*, or small reservations of wood exist, or can be formed, but in crowded districts, such as Sir Steuart Bayley describes, the question is a most difficult one. With reference to native States, I should like to make a few remarks. In Jeypore enormous progress has been made in the extension of tank irrigation. For many years past, under a most enlightened Government, Colonel Jacob has been able to form many artificial lakes for the storage of the rain water, and I know that the land which has been irrigated from them has yielded a very large increase of revenue; and that that able engineer has had the pleasure of seeing many valuable lives preserved by the water which has been made available by his skill, during times of scanty rainfall. The inhabitants of Rajputana have always been fully alive to the necessity of storing water, hence there are many fine lakes in the country which have been formed, chiefly as famine works, by constructing huge embankments across streams, at suitable points in the hills. The one thing on which both nobles and ryots in Rajputana

seem to be agreed is the determination to get all they can out of the soil; and they are ready to adopt any improvements, provided it does not involve too great change, and they can thoroughly understand it. Dr. Voelcker's remarks on the treatment of cattle are most instructive. Sometime ago I placed copies of a popular manual on cattle diseases, which was drawn up by the Indian Government of Revenue and Agriculture, in all the dispensaries under my care, and instructed the hospital assistants to read them to the ryots, and to help them whenever possible. The results have been most gratifying, as I have been frequently informed that valuable animals have been saved by the timely advice received. In such ways different departments can assist each other, and all can see that they are working for the common good.

Mr. H. C. Hill (Conservator of Forests in India) writes:—Dr. Voelcker has very correctly said that the Forest Department in the early days had no agricultural object in view. Its objects were, and still are, mainly sylvicultural; at the same time it must be admitted that for many years in certain places, and in Ajmere, Merwarra particularly, the entire strength of the Forest Department has been devoted to the production of grass and fuel on the borders of cultivation. Dr. Voelcker now recommends that forests, under the name of fuel reserves or village forests, should be more generally created and preserved near to cultivated lands, in short, that what has been done in Ajmere should be extended to other provinces. The only difficulty in giving effect to Dr. Voelcker's proposals lies in the fact that such lands as would answer the purpose are no longer at the disposal of Government, and must be bought or acquired in a costly manner. In Ajmere the fertile plain is intersected with a network of bare, rocky hills, totally unfitted for cultivation, and admirably adapted for the production of grass and firewood. It was an easy matter to take up and preserve these, but the rich plains of the North-West Provinces, for instance, have no such sterile, well-defined uplands, and the *usar* lands are so interspersed with cultivation that they could not be separately demarcated and controlled, and the reservation of compact areas would necessitate the inclusion of some cultivable land of high value. The question at once arises, Is the State justified in expending large sums for the indirect benefits Dr. Voelcker sets forth, viz., in order to guard against the deterioration of the soil, and in order to maintain the Land Revenue? Admitting that experts correctly foretell a steady deterioration of soil and a falling off in revenue, the evidence of past years at least demonstrates that the process is extremely slow, and I venture to think that until the agriculturist has been taught to feel that wood is a need, and that in paying for firewood and using cow-dung as manure for his fields he is making a good investment, there is but little prospect of land being acquired and set apart to supply that need. When once the cultivator demands wood, there will be no difficulty in elaborating financially sound plans for its production, wherever water is sufficient. It is, we all know, quite impossible to grow wood without water, from some source or other. I do not anticipate that the management of such forest tracts as Dr. Voelcker contemplates would entail any expensive management, or that the scheme would collapse from the costliness of forest experts referred to by Sir Steuart Bayley. There is one other point to which I should like to refer. I think it is not generally understood that every reserve, every State tract, is a fuel reserve, in the sense that it is quite impossible to grow large timber, either teak, deodar, or sal, without, at the same time, producing in the branches and in trees of inferior kinds a mass of firewood, which is many times in excess of the requirements of the cultivators living around the forests within that radius, to which so cheap a commodity can be carried. It is quite possible that, on certain rocky, poor soils, with limited rainfall, only grass and scrub, such as would meet agricultural needs, can be grown; but it is equally certain that the high forests on richer soils meet the same natural requirements quite as fully, while yielding the more valuable larger timber. In conclusion, I consider we are indebted to Dr. Voelcker for reminding us that the preservation of forest areas nearer to cultivation than, as a rule, they exist, is to be aimed at; and I am confident that his recommendations will bear fruit.

Mr. John Hughes (Consulting Analyst to the Ceylon Planters' Association, 79, Mark-lane, E.C.), writes:—Of the several points raised by Dr. Voelcker's paper, perhaps the most important was the much debated practice of burning cow-dung cakes, or *bratties*, as fuel. This practice is undoubtedly a waste of valuable manure to a certain extent, but it has grown into a custom in the neighbourhood of towns from necessity and not from choice, and is therefore excusable under present circumstances. Indeed, if the ashes of these *bratties* were carefully and systematically returned to the land, the practice is after all not so wasteful as might be supposed. According to my own analyses made some years since, and referred to in the *Journal of the Society of Arts* for March 21st, 1890, one ton of sun dried *bratties* contained the important plant food constituents in the following proportions:—

Lime	43 lbs.
Nitrogen	33 ,,
Potash	14 ,,
Phosphoric acid	12 ,,
	102 lbs.

When such a manure is burned as fuel, the nitrogen, which exists in the form of organic matter, becomes converted into gaseous products, which are either absorbed from the air by growing crops, or brought

down by the rain and absorbed by the soil for future plant food. Therefore, this supposed loss of nitrogen does not occur to the full extent generally supposed, while the whole of the mineral salts, which include the lime, potash, and phosphoric acid, remain in the ashes, and, under proper sanitary arrangements, should be carted out on to the land. It should be remembered that, in round numbers, 80 per cent. of the atmosphere consists of nitrogen in a free form, and that recent scientific research has clearly demonstrated that leguminous plants, such as clover, peas, beans, &c., have the natural property of absorbing this nitrogen and yielding a large crop of albuminous fodder, while the soil, by reason of increased development of root growth, is left richer, and better able to produce other crops. What leguminous crops, therefore, are specially able to do, other crops may be able to do to a smaller extent, so that, in a tropical climate, nitrogen may be the constituent most easily obtained by natural means, and therefore the artificial supply, in the form of manure, is the less necessary. Indeed, the general custom of burning the stubble and destroying by fire the nitrogenous organic matter contained in the straw, clearly indicates that, in India at least, the soils are not specially in need of nitrogen. In our more temperate climate such a practice would be regarded as unnecessary and wasteful, though at times, and on certain soils which have accumulated too much humus and are also somewhat stiff, it is usual to pare and burn the turf; and the late distinguished chemist, Dr. Augustus [illegible] (the father of the lecturer), specially comm[illegible]t as a sound agricultural operation, pointing [illegible] that inert vegetable matter was converted by pa[illegible] and burning into highly effective plant food. Further, that the beneficial effects of a fair quantity of vegetable ashes upon root crops, on certain soils, are more striking than the effects produced by guano superphosphate and other artificial manures. In conclusion, it may be pointed out that India has produced crops of corn, rice, and grain for centuries with apparently but little loss of permanent fertility in the soil, and the fact that some 40,000 to 50,000 tons of boxes are now being exported annually to Europe, certainly suggests the idea to practical men that there cannot be any great demand in India for one of the best and most lasting fertilizers.

Mr. H. J. ELWES, writes:—After so many men of great official eminence and life-long Indian experience have spoken, there is not much left to be said by one like myself, whose knowledge of the country, through spread over twenty-two years, has never been continuous. I must, however, remark on one point which Dr. Voelcker has not mentioned, and that is the little interest which seems to be taken in agriculture by Government officials generally, and native gentlemen and landowners. Instead of being, as in England, an occupation in which the Royal family, landowners, and men of rank take a lively personal interest, it is in India an occupation for humble ryots, and in consequence it is more or less neglected and despised. Of the numerous Indian students who come to the Royal Agricultural College, I have only known one who came on his own account to learn what ought to be a necessary branch of education for men whose living is derived from agricultural rents, as I also think it should be for Indian civilians generally. The remainder were merely qualifying themselves for official positions. As long as agriculture was looked down on in this way in Europe, it remained in a primitive state, and nothing will tend so much to its improvement in India as the example which might be set by native gentlemen improving their own estates and the position of their own tenants. I most fully concur with what Sir S. Bayley said as to the great number of ill-bred and half-starved cattle which infest Bengal and Assam, and which are often unable, from weakness, to do any work. Half, or one-third the number, if better fed and looked after, would be of greater value; but the climate and soil of Eastern Bengal is very unsuitable to the development of either a fine race of cattle or men, and the Bengali is usually the worst beast master of any race I have seen in Europe, Asia, or America. I cannot at all agree with Dr. Voelcker as to silage being unsuited to the country. On the contrary, I believe the system, when thoroughly understood, would afford a constant supply of wholesome food to cattle, which are now systematically starved in the dry season; and the coarse nature of most native grasses seems to make them much better adapted to silage than to hay. But it requires very long practical experience to make good silage, and to know how to use it to the best advantage. After twelve years of personal attention to the art in England, I am only now beginning to think I know something about it. And yet the system has been often condemned on account of the failure of persons whose only knowledge was gathered from books or chemical experiments. In Indian agriculture, as in English, practice must come before science; and what Dr. Watt has told us to-day, does not in the least surprise me, after seeing, in many parts of India, the most foolish and unpractical attempts made to carry out European agricultural practices by persons who, however able in other ways, had no practical knowledge of agriculture. Schoolmasters will never be able to teach agriculture, or to get farmers to listen to their advice, either in England or India, unless they have a personal practical acquaintance with the numerous difficulties, which so often make it impossible to carry out scientific agricultural principles in a profitable manner. The best farmer is not the man who produces the largest result, but the one who shows the best balance of profit. With regard to green manuring, as a cheap means of supplying nitrogen, I think Prof. Wallace is rather too sanguine, and would much prefer, where clover or other leguminous crops can be grown in India to turn them into good cattle

food, and thus supply manure. Perhaps the most difficult of all the questions which have been raised is the supply of fuel and grazing, and this is essentially one which can best be dealt with on large hereditary estates, where the owner not only knows but cares for the wants of the people, and the system of management is continuous. No forest department, however large or however able, can deal with such a question as this; but resident landowners can, and would do it, if it was fashionable and profitable to plant trees as in Europe.

Mr. W. SOWERBY writes:—There are a few points upon which more information might have been given. There is, for example, nothing whatever said about the possibility of obtaining in India mineral manures, such as lime, phosphates, nitrates, &c. Every country in the world has been ransacked to obtain these valuable fertilizers, but nothing whatever has ever been done in India to find such useful minerals. The evil effects of denuding forests not only in India, but in every other country, and the beneficial effects of conserving them, goes without saying; but whether the growth of wood for fuel to prevent the natives from burning cattle manures can be effectively carried out is a difficult question; for the carriage of such wood fuel to any great distance, unless by cheap water carriage, would make the fuel more costly than it was worth. There are no doubt in India many undeveloped coal fields which should afford great supplies of fuel.

General MICHAEL writes:—Sir Steuart Bayley, in his speech, questioned the practicability of the Government being able to acquire land readily for village fuel reserves. I don't know how this may be in Bengal, but in Madras there would, I believe, be little difficulty. Lord Reay, who sat next to me at the meeting, told me that he thought there would be no difficulty in many parts of Bombay.

Miscellaneous.

MOSCOW CONGRESSES.

The *Société Impériale d'Histoire Naturelle d'Anthropologie et d'Ethnographie* is making arrangements for the holding of two International Congresses, one of Prehistoric Anthropology and Archæology, and one of Zoology, at Moscow, in August next. The following letter to the Secretary of State for Foreign Affairs, from the Russian Ambassador in London, has been received from the Foreign-office, through the Science and Art Department:—

Londres, le 18/30 Mars, 1892.

Monsieur le Marquis,—

Le Ministère de l'Instruction Publique vient de m'informer que la Société Impériale d'Histoire Naturelle, d'Anthropologie et d'Ethnographie se proposait d'organiser dans le courant de l'été prochain deux Congrès Internationaux, d'Anthropologie Préhistorique et d'Archéologie, et de Zoologie, dont le premier doit siéger à partir du 1/13 au 8/20 Août, et le second, du 10/22 au 18/30 Août.

Le Gouvernement Impérial étant trés désireux de s'assurer la participation des savants Anglais à ces réunions scientifiques, a chargé l'Ambassade de recueillir les souscriptions et de délivrer les reçus, dans le but de faciliter à ceux d'entr'eux qui voudraient se rendre à Moscow, le versement de la cotisation, dont le montant est de 20 frcs. pour l'un des congrès et de 30 frcs. pour les deux.

En portant cette invitation à la connaissance de votre Excellence, avec la priére de lui donner la publicité qu'elle jugera convenable, je crois devoir ajouter que le Consul Général de Russie à Londres a, de son côté, pris des mesures pour en informer directement les sociétés suivantes:—

1. British Association for the Advancement of Science.
2. Society of Biblical Archæology.
3. The Anthropological Institute of Great Britain and Ireland.
4. British Archæological Association.
5. The Archæological Society.
6. The Royal Society.
7. The Zoological Society.

J'ai l'honneur d'être, avec la plus haute considération, Monsieur le Marquis, de votre Excellence le très [illegible] très obéissant serviteur.

(Signed) STAAL.

A S. E. le Marquis de Salisbury, K.G.

BOOK TRADES' EXHIBITION IN AMSTERDAM.

Information has been received from the Foreign Office, through the Science and Art Department, that an International Book Trades' Exhibition will be held in the Palais de l'Industrie at Amsterdam, in July and August, 1892. The Exhibition is arranged by the Librairie Néerlandaise, which thus celebrates the seventy-fifth year of its existence. The heads of classification are as follows:—Group A. Books of the present time in all forms, music, journals, and maps; B. Printing, type founding, inks, woodcutting, &c.; C. Copper and steel engraving, etching; D. Lithography; E. Reproduction processes by means of photography; F. Binding, leather and other materials; G. Paper; H. Account books, almanacs, letter paper, pens, pencils, &c.; I. Libraries, shelving, book plates, &c.; K. Retrospective exhibition.

The Telegraphic Address of the Society of Arts, and of the Royal Commission for the Chicago Exhibition, is "Praxiteles, London."

Journal of the Society of Arts.

No. 2,057. Vol. XL.

FRIDAY, APRIL 22, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Chicago Exhibition, 1893.

The Royal Commission are now able to announce that, her Majesty's Government having increased the grant placed at their disposal for the purposes of the British Section, from £25,000 to £60,000, they can dispense with any charges for space at the Exhibition, and will return to the intending exhibitors the amounts already paid on that account.

The available space in the General Manufactures Building is now almost entirely filled. Exhibitors in this department should therefore lose no time in applying.

In the Agricultural Building, and in the Machinery Building, space is still available.

All applications must be made upon forms to be obtained from the Secretary of the Commission at their offices, Society of Arts, John-street, Adelphi, London, W.C. They must be sent in, properly filled up, and addressed to the Secretary, as above.

FISHERIES DEPARTMENT.

The following communication has been received from Mr. J. W. Collins, Chief of the Fisheries Department of the Exhibition :—

Sir Henry Trueman Wood, Secretary Royal Commission, Chicago Exposition.

Dear Sir,—I have the honour to enclose herewith, for your information, copy of circular letter that I have recently forwarded to various people throughout Great Britain, who are interested in the fisheries, with the hope of securing their co-operation and interest in making a thorough display of the British fisheries at the World's Columbian Exposition.

Yours very truly,

J. W. Collins,

Chief, Department of Fish and Fisheries.

I have the honour to respectfully represent to you, that, in accordance with the official classification of the World's Columbian Exposition, there has been created a "Department of Fish and Fisheries," and that there will be erected a group of buildings especially constructed for the accommodation of exhibits of fish, fisheries, and fish culture.

It is my present purpose in writing chiefly to show what has already been accomplished, and to state certain facts that, perhaps, have not been previously brought to your notice, or fully elucidated.

1. The fisheries buildings are practically completed. They will fully meet the requirements for which they have been erected. It is conceded on all sides that they are not only wonderfully beautiful and harmonious in arrangement, from an architectural standpoint, but that they are peculiarly well adapted to the needs of a fisheries exposition. It is, therefore, easy to arrange the exhibits in separate buildings under general groups—aquaria, commercial fisheries and fish culture, and angling.

2. Space will be awarded, free of cost, to applicants who desire to exhibit.

3. As is usual at expositions, awards will be made by competent juries.

4. The management are in negotiation with the transportation agencies as to rates, and the most favourable terms are expected; already important concessions have been made, and every facility will be accorded displays sent from foreign countries.

5. The Columbian Exposition offers to exhibitors exceptional opportunities for bringing prominently to the notice of the world the business in which they are engaged.

6. Material intended only for exhibition will not be subject to customs duties, like ordinary imports.

It is believed that a large and instructive exhibit, such as will be brought together at the Columbian Exposition, will not only promote trade interests, but will aid materially in securing recognition for the fisheries, and tend to enhance their prosperity and development.

Reservation of space in this Department has been tentatively made for the instalment of exhibits from your country, and it is expected that the British fishing interests will see the advantage of sending collections that will fairly illustrate their trade.

Blank forms of application for space and other data of interest to intending exhibitors can be secured by addressing the Secretary of the Royal Commission appointed from your country, Sir Henry T. Wood, Society of Arts, John-street, Adelphi, London.

In conclusion, it is proper to state that the regulations of the Exposition require that all foreign Commissioners shall report, not later than November 1st 1892, the amount of space necessary to accommodate exhibits from their respective countries. It is therefore needless to say that this matter should receive the prompt attention of intending exhibitors, in order that they might not be deprived of any advantage.

Proceedings of the Society.

APPLIED ART SECTION.

Tuesday, April 12th, 1892; Lord MASHAM in the chair.

The paper read was—

ENGLISH BROCADES AND FIGURED SILKS

By C. PURDON CLARKE, C.I.E.

The subject of my paper being restricted to those varieties of woven silk known as damask, brocade, and brocatelle, it is unnecessary for me to instance the many proofs of the great antiquity of silk culture, and of the manufacture of plain woven silk fabrics. We can concede the claim to its origin to China, where, it is related, twenty-six centuries before Christ, the rearing of the silkworm was the pastime of royalty; and the Empress Cse-ling-she is credited with the invention of the first loom. Whether that loom was for plain weaving, or capable of producing figured stuffs, we are not informed; but it is probable that 1,000 or perhaps 2,000 years elapsed before the draw-loom developed sufficiently to produce the ancient examples recently found in Egypt. It is true that early writers describe woven stuffs, rich in pattern, like that which Homer gives to Ulysses, where a decorative hunting subject, interwoven with a gold ground, presents to the mind's eye a garment not unlike a *shikargah*, or hunting ground pattern of Benares or Ahmedabad; yet the weight of probability is in favour of such fabrics having been figured either by hand embroidery, or woven in a tapestry loom, between which and the simplest form of figure weaving loom there s a gulf which must have taken many centuries to bridge.

The difference between these two methods of weaving is great, and yet so little known, even to many whose connection with the arts leads them to continually mention, and often to confuse, the two under one name, that a short description of both these processes is necessary.

In true weaving, whether of silk or other fabrics, the loom is a framework carrying the warp or threads which run the long way of the stuff, and the whole process of weaving consists in working a transverse thread—the weft or shute—which, passing alternately over and under the threads of the warp, forms the structure of the fabric. It is probable that, in the first looms, the needle was employed to carry the thread for this purpose, and this needle, working laboriously in and out each warp thread, produced a coarse fabric at a slow rate, and of very uneven texture. Then came the invention of the heddle harness and reed, in which, by pulling a string or pressing a lever with the foot, alternate sets of warp threads were raised or depressed, and the needle, becoming a shuttle, shot the whole width of the stuff at one operation in less time than it took before to turn round a single warp thread. The earlier process had been as simple as basket-making or, at the utmost, the plait of a straw mat; but now the true loom was started, and soon, by increasing the number of heddles, and changing the sequence of the alternation of warps, diagonal, chevron, and diaper patterns were formed, and, gradually, more complicated figures produced.

The tapestry-loom is the primitive form of the machine, and, as it was 3,000 years since, so it is to-day, whether working at the Gobelins or in Asia Minor and Persia—where the *kehlim* carpet and curtain is the product of the same loom, and made in the same manner. In this we have the frame and warp threads, but there is no through weft, excepting where a single stripe of pattern crosses the whole width of the stuff. The process of manufacture is very simple, the pattern being produced by interweaving by hand, the various coloured threads in a manner similar to the making of a basket, and as the needle carrying each colour, after travelling its width has to return along a parallel path wherever a difference of colours occurs in a straight line in the direction of the warp, there is no connection between it and the next colour, leaving open slits in the stuff in wall tapestries — where such lines, in architectural subjects, are of frequent occurrence—an amount of sewing has to be performed to hide this defect in the weaving. For this reason the *kehlims* of Syria and the *dhurris* of India have no lines in the direction of the warp, but form patterns in zig-zag.

The hand-made carpet looms of the East, and the shawl looms of Cashmere, are half-way between the tapestry and the figure-weaving loom. Like the tapestry, the pattern is worked in and out by hand; but they are true looms in having heddles to separate the warp-threads, and shuttles to throw a weft-thread, which in this case—hidden beneath the pattern—serves to bind the fabric together.

We can only conjecture respecting the class of woven fabrics described in the Odyssey and

the Iliad, but we can now speak with positive certainty of the looms as far back as the second century, owing to a valuable find of early stuffs at Akhmim, in Egypt—from which a large and valuable collection can be seen in the South Kensington Museum. Here we have weaving in a state of perfection which has been little improved upon in our days, and each type of loom work is well represented in this collection. Amongst these fabrics are some which are the earliest examples of brocade weaving yet found, representing the period commencing with the Ptolemaic dynasty, and ending only after the Saracen conquest of Egypt.

Then, in our own England, the dresses which, at the beginning of this century, were found enveloping the body of St. Cuthbert, at Durham, add a 10th century link to our chain of examples. These stuffs were probably the work of Saracen settlers in Sicily. An examination of this series of brocades shows that, even at this early period, a whole system of mechanical weaving was practised; and it is this that should be clearly understood, and not in any way confounded with the weaving of tapestry work.

In the early figure looms, only geometrical figures with small repeats were worked, but, as the patterns grew fuller in design, the system of heddles and harness a series of strings and levers, had so complicated the loom, that it became impossible for the weaver to remember the right sequence of changes in shuttle and lever, and then an elaborate system for the transfer of a drawn pattern to a pedal and shuttle notation became necessary; and the weaver merely performed mechanical duties, whilst the actual artistic work was done by the mounter of the loom, before a single throw of the shuttle was made.

An example of the weavers' notation is here to-night, and it is absolutely certain that a similar system was used in a piece of Damascus brocade, found at Akhmim, from a trifling error in each repeat, which could only be due to an error in the notation.

Having traced the figure-weaving loom back at least to the second century, I must now speak of its introduction into England, and about this can only say that the date is still very uncertain. It is not an industry suited to small production, and by no means a village craft, capable of being carried on by single artisans in their own homes. At the present time as much as several hundred pounds—after three or four months' work of men in several branches of trade—is required before a silk hand-loom can be set in working order, to produce some of the brocades exhibited here to-night, even in one of the humble dwellings of a Spitalfield weaver, who is the owner of the loom-frame only, and not of the jacquard or mounting; and in India, to this day, the people who set up a loom for the weaver of *kincob* take 45 per cent. of the gross selling price of the material for their labour. The system by which such a costly trade could be carried on by artisans in their own homes is, as I have already stated, by the means of capitalists, who, in old times, were often the retailers.

As purely an article of luxury, a knowledge of the fashion of the period is all important in commanding a sale for the production, and as no weaver could undertake the risk of weaving a design unless sure of a sale, the capitalist became the actual manufacturer, and the weaver little more than a part of the mechanism of the loom and, paid by the piece, was well rewarded when he joined industry to dexterity. It was only at the commencement of direct European trade with the Indies, and the introduction of silk culture to Italy and France, that the lowered price of the raw material enabled it to be imported in sufficient quantity, and then silk-weaving became a leading industry in France, and was afterwards introduced into England, but was only established as an important manufacture in this country upon the immigration of the Flemish weavers in the 16th century. It was at this time that we begin to find considerable records of figure loom weaving, amongst which is the grant of a Charter by Queen Elizabeth, in 1564, to the Dutch and Wallon settlers in Norwich.

Three hundred families of these refugees were settled there by the Duke of Norfolk, and, with other trades, they introduced damask, flowered and striped silk weaving. A hundred years later, the revocation of the Edict of Nantes strengthened our silk trade by the expatriation of a large number of French weavers, and to these is attributed the foundation of the silk industry of Spitalfields. The Flemish and Huguenot weavers formed settlements in various parts of the country, and besides London, Kent, Essex, and Norfolk became seats of manufacture, whilst others in fewer numbers, migrated north and west. Several of these remain unchanged, and Spitalfields still takes the first place in the country for hand-loom work, whilst the figure-looms of Canterbury and Norwich have ceased to work, the latter having, early in the century,

rivalled and even excelled the shawl weaving of Cashmere. The figured ribbon manufacture at Coventry has survived many vicissitudes, whilst Macclesfield, starting with a lighter class of fabrics, is becoming a centre which will eventually furnish dress and furniture silks equalling those of the southern factories. Nor ought I to forget to mention the hand-looms at Leek, the power-looms of Halifax, Patricroft, near Machester, Glasgow, and other rising places in the north—the great mechanical country—where the future of silk will probably be secured. The looms used by the early weavers remained unchanged until the beginning of the present century, when an ingenious Frenchman sent to a Workmen's Exhibition, at Paris, a machine for simplifying net and ribbon weaving. Through the advice of General Carnot, the grandfather of the present President of the French Republic, Napoleon I. instructed this workman to attempt the application of his invention to the draw-loom, which had been already improved by Vaucanson fifty years earlier. The great mechanical genius of Jacquard was equal to the task, and the overgrown complication of the draw-loom and its attendant boys became simplified, and by adapting the fly-shuttle—which had been used in England fifty years earlier—labour in producing wide stuffs was reduced to a minimum. By Jacquard's system the machine automatically read the pattern notation, instead of having it read by the draw-boys, and so perfect is this loom that, although power looms will produce the bulk of brocade and damask in the future, the hand-worked Jacquard loom, in its present form, will probably always remain as the handiest for the higher class work.

This manufacture, so wide-spread for a time, did well, and until the treaty of 1860 opened the market to the competition of foreign producers, a large population was comfortably maintained by the practice of this beautiful art. In 1825, London possessed over 24,000 looms, employing 60,000 hands; but after a few years of free trading, the number of looms dropped to 1,200, and the weavers to 4,000. A few years before 1860 our imports of foreign silks were but £2,365,415. In 1889, they had grown to £11,000,000; and it is to secure again to our wage-earning population a large proportion of the enormous sum which annually is thus sent abroad, that our best endeavours are needed.

It would be of great assistance to this good work if it was possible to dispel the misconceptions and prejudices now retarding a natural development, which may rival that of the great cotton manufactures of Lancashire early in the present century. The first of these is that the English silk is dearer than the French, and this is so wide-spread that even our manufacturers share it with the public. The brocades and figured silks you see here to-night cannot be made and sold by either France or Germany at the price that these are sold for; imitations can, and to explain this I must refer to an unpleasant matter, but one which is of vital importance, not only to our manufacturers, who lose the trade, but to the buyers of the foreign substitute by which our goods are undersold. To render silk capable of being dyed, certain operations of scouring and washing have to be gone through, and these result in a loss of weight of as much as one-fourth; therefore, a skein weighing 16 ozs., after dyeing, is returned to the weaver with only a weight of 12 ozs. To make up for this loss, it was the practice to use certain chemical substances, which, actually combining with the silk, took up the dye, and, for a time, the weavers were content to receive back their skeins without much loss of weight. Rival dyers, however, soon competed with each other in increasing the weight and substance of the silk yarn, and, by leaps and bounds, in black silks, this increase went on, till 16 oz. of silk was returned by the dyer, weighing 36 oz., then 50, and, eventually, 100 oz. For a long time, only black silk would bear this load, but the discovery of the use of salts of tin enabled the dyers to apply it to other tints; and the French, who have always shown great cleverness in applying chemistry to the arts, turned the process to such profit, that they are almost able to dispense with the raw material. By the adoption of these and other silk substitutes, the foreign manufacturers are enabled to produce fabrics which, sold as silk, make our dress and furniture stuffs appear dear in comparison; but, when we insist upon having the same quality in pure silk, fast dyes, and close weaving, then our own productions beat the foreigner's in price, and will, I trust, before long, in design also.

Another prejudice is, that for beauty of design, we must always remain inferior to the French. This leads me to place before you a problem. I have recently had to compare French and English weavers' pattern-books, dating from 1750 to the present time, and I found periods when there was no difference in quality, and

then, both running off, apparently in rivalry, in an endeavour to produce the crudest colouring and most vulgar designs the mind of man could imagine. In these the French, with their superior daring, especially in wrong-doing, excelled, and the patterns of the time of Louis Philippe were even worse than ours. With the second Empire, however, they went ahead, and although we followed closely, it was but following, except where original paths were struck out by irrepressible genius, and our manufacturers—or rather the middlemen who dictate to them—were forced by public approval to turn from France and unwillingly submit to the dictum of an English designer. Thus Owen Jones, in the "fifties," tried to free ornament from the restraints imposed by the attempted representation of natural objects. His work was beautiful, but it was the beauty of a snow crystal—wanting in human interest. Then Dr. Dresser, who, at first following in the same path, re-admitted natural forms, and was one of the first who showed British manufacturers in many trades that the public would accept and pay good prices for original English designing. But the great change came as a tidal wave; and it would be doing injustice to many, if I attempted even to give the leading names of our artist designers of the past 20 years. Nor does time permit me to even sketch the strong influence of Japanese and Persian art, and the result of the flooding of our markets with the textile treasures of Turkey, after the war of 1887. All these have helped to enlarge our ideas on the beautiful in Art, and to free us from the forcible adherence to a few fixed and often lifeless styles. It is in this path that we owe so much to the the great and beneficial influence of the work of William Morris, in silk, as well as in many other classes of applied decorative design; and it will be only when the history of this century comes to be written, that the greatness of this work will be more evident and better understood than it seems to us at present, especially when the importance of the social and economic principles involved will be acknowledged, and an art, ennobled and elevated, will stand clear from foreign styles of design which often, at their most prosperous periods, were associated with vicious and rotten conditions of society, as false as their own art principles.

There is another disability from which the trade suffers, in its competition with the foreign producer, that is, the evasion of taxation by the foreign goods, and this to an extent which is so considerable that, if the Chancellor of the Exchequer could only devise means to prevent what is actually a gross fraud, not only would the competition be weakened, but our revenue would be strengthened, probably to the extent of some millions. The Spitalfields loom-master not only has to bear the whole brunt of imperial and municipal taxation in his factory in the East-end of London, but again in his city office. He has, in addition to the cost of an extensive establishment, to pay his full taxes, and also the income tax on his profits in many cases in such a manner that although one business, he is practically paying taxes twice over. I am informed that business to the extent of many millions per annum is carried on in the City of London, and the leading commercial cities, by agents of foreign houses, who pay diminutive rents for small offices, do all their business with samples, keep no books, receive no payments in England, and only pay income-tax on a fixed salary. In some cases these people are suspected of being partners of a foreign house; their share of profits is not declared, but accumulates in their own country until, after some years of successful trading, they return to it. This not only applies to the silk trade but to many others; in fact there are few trades in the City where these foreign agents do not swarm and carry on business, receiving the benefit of our protection in all parts of the world, whilst they practically evade sharing in the cost of the Empire, which falls so heavily upon our own people.

Another misconception is that hand-woven silks must necessarily be so much more expensive than those produced in the power-loom. Actually, in high-class work, the difference is not so great, as, in both, the cost of the raw material and the setting of the pattern in the loom remain the same, and these, unfortunately for the weaver, are the principal items in the value of a yard of silk. With respect to the power-loom, the work produced by it differs very little from hand work, as each loom is attended by an experienced weaver, who, whilst giving the same watchful attention, is saved the heavy labour with the foot-pedal which is a common source of permanent injury to many.

As I have already shown, the beauty of the pattern does not depend on the weaver, his duty being solely to perform certain actions which require vigilance of eye and dexterity of hand, but little thought. The softness, or rather looseness, of some hand-produced goods can equally be obtained in power-weaving, but this quality, dear to artists, is not regarded by the

manufacturer in the same light. The hand-woven linen fabrics—some named after our greatest art critic, which are selling at prices equal to silk—could equally be produced by power; and many of the old Venetian and Turkish brocades are the result of work so bad that a power-loom would have to be out of order to perform it, and the yarn not regularly spun by perfect machinery, or even a trained hand-spinner, but twisted somehow from a distaff from imperfectly prepared fibre.

Before commencing the notice of the examples of silks kindly lent by different manufacturers to illustrate my paper, I must mention a source of strength, especially in the matter of design, and that is the practice of engaging looms, either in factories or at the homes of the weavers, by the leading furnishing and decorating houses. This has, in recent years, done much to remove the reproach of producing stuffs artistically inferior to the French. Charged with the decoration of palaces and the houses of the wealthy, these firms—forced to seek beyond the stock patterns of ordinary commerce—have, therefore, engaged the assistance of skilled artists and designers to produce patterns which, to a great extent under their own personal superintendence, were put on the looms, and carried to a perfection the maker for the general market could not afford to attain. Although the copyrights of these designs were generally secured to their owners, yet the influence spread, to the general benefit of all concerned. Some of the principal amongst these firms have lent examples of these engaged silk patterns, and a description of these will be given in their turn.

This system of engaged patterns is but a development of the old custom of engaged looms; and I am informed that the bulk of the so-called manufacturers in Lyons, do not actually possess a single machine, but, free from the heavy strain of capital sunk in machinery and rents of large factories, devote their energy and capital to negociation, first, of the designs and the purchase, dyeing and preparation of raw material, then the disposal of the goods when made.

In attempting a description of the figured silks I have to congratulate my audience and myself that I resisted the proposal to include other classes of English silken fabrics with brocades and figured silks, as no evening would have sufficed for the purpose. Indeed, I feel that the few lines of notice, which is all that my space permits, to a small selection of typical examples, is not in any way fair to the lenders of art works, which have cost them something more than time and money. In several cases I collected sufficient materials for a good monograph in the history of a single factory; and my hope is, that this poor effort of mine will bring in separate papers on different localities, many of which will repay the explorer, by their richness in old world memories, whilst up to date in practical working.

Beginning with Spitalfields, where the hand-loom factory of Messrs. Warner and Co. is one of the largest and most important. Amongst their silks will be noticed a large cloth of gold brocade—a veritable Indian *kincob*—the order coming from India, where it is impossible to hand weave stuff of such great width. The next is a damask pattern, designed by Owen Jones 30 years back, the following details of the manufacture of which, I think, will prove interesting. This fabric is woven in a hand-loom controlled by three Jacquard machines, requiring a *mounture* and harness, consisting of 29,088 threads in the width of 63 inches. Every one of these threads has a work to perform in forming the pattern, and, in the mounting of the loom, has been attached by a small glass pulley to one of the warp threads. The warp used in this piece of 60 yards used up 1,022 miles of silk thread, and, in addition, 757 miles of silk was consumed in the weft. Each of these warp and weft threads consists of 15 fine threads as produced by the worm — thus the piece contains 26,355 miles of silk as rolled off the cocoon, requiring about 100,000 cocoons to produce this quantity. The lengths of the repeat in the design is 28 inches, and in consequence of the fineness of the texture of the material, 9,312 perforated cards had to be cut. These cards are laced to form an endless band, and measure 1,000 yards in length and weigh 5½ cwt. The whole pack of cards has to be turned over each time the 28 inches of design is woven, each card taking its turn singly against the needles in face of the Jacquard cylinder, so raising and depressing the threads of warp, thus causing the openings through which the shuttle passes. This small pattern, only 28 inches long, required to be placed on ruled paper, sufficiently large to show visibly each thread. This measures 16 feet by 9 feet 3 inches, and contains 5,587,000 small squares.

Messrs. Collinson and Lock show some Spitalfields silk, which cannot be rivalled for beauty of design or technical excellence of

manufacture. The Louis XVI. brocade, in silver figure on a rose Du Barry ground, was made for the Palace of Charlottenberg; and the heavy cloth of gold brocade, which glows with the tints of a late autumn sunset, will in a few days grace the walls of a saloon in the Rue de Rivoli. Messrs. Gillow also show valuable reproductions of early 18th century loom work, and can claim an unbroken history of over 200 years' connection with Spitalfields furniture brocade. Messrs. Helbronner are the possessors of many special designs, and besides their Spitalfields productions they employ many hand looms in the old Huguenot settlement at Braintree in Essex.

Liberty's dress silks are well known, and amongst these Spitalfields and Braintree occupy the first place, although, for lighter figured silks, the examples from Macclesfield, Halifax, and Glasgow offer beauty and quality, which no similar foreign silks can equal at the price. Messrs. Debenham and Freebody have never failed to support British made silk, and have used their utmost influence in securing for Spitalfields the orders for the richest court dresses of many seasons past.

Some examples of Messrs. Bailey, Fox, and Co.'s loom work are also shown—figured silks and brocades—and are of equal rank with the higher class Spitalfields manufactures. The other Spitalfields silks, which have been lent to illustrate this paper, include examples from Messrs. Buckingham, Messrs. Burnet, and Messrs. Goodyer, and are instances of the great national characteristic of doing things thoroughly and well, when we properly set about it. Examples of these silks, at the Paris Exhibition of 1889, were challenged by French manufacturers, who refused to believe that they could be produced in England; and, I must own, that I did not feel sufficient confidence to publicly claim such beautiful art works as English, until I had personally seen many of them on the Spitalfields looms; and, looking back through old pattern books over 150 years old, I find that the power to produce these designs had always existed, only waiting for business men, like Mr. Lock, to come and set them on the right path.

Messrs. Walters' Essex factory, at Braintree, combines the Spitalfields hand-loom system with a large steam factory, where power-looms are ready to meet the demands for large quantities in the small limit of time that modern commerce is forced to demand. The damasks include reproductions of old Chinese stuffs, and the brocades for upholstery work are scarcely surpassed by the best French looms. An interesting exhibit from Braintree is the original drawing of a design made by Prince Albert for some hangings for Buckingham-palace, in 1850, since which time Messrs. Walters have woven most of the silken walls there and at Windsor Castle.

Then, further north, the brocades from Messrs. Bermingham, of Leek, a town where silk is the principal industry, and, for dress purposes, the lighter but beautiful silks of Halifax, Macclesfield, and Glasgow, of which specimens have been lent by Messrs. Liberty and Co. I cannot attempt to give the names of more than a selection of manufacturers, and I know that I am doing an injustice to many weavers of brocades and dress stuffs by not mentioning them, especially the beautiful figured poplins formerly called "tabinette," which are made by such makers as Pim, Dunn, and Atkinson, of Dublin. But before leaving these examples, I should like to call your attention to a new direction in figured weaving, shown by samples of loom embroidery from the mills of J. O. Nicholson, of Macclesfield. This suggests infinite developments, and especially merits the attention of artists, as it forms the solitary instance I know of in the whole art of weaving where, without labour or fatigue the artist can direct the pattern, and, "fancy free," transport his thoughts to the stuff almost as easily and as speedily as he could with a brush of colour or a sheet of paper.

It was not my intention, when first taking up this subject, to do more than allude to the past, as the practical question before us is really that of the present and future, and about that future I have no doubt. Although for a period depressed—if not almost completely extinguished—figured silk weaving is not a moribund industry. Its vitality is proved by its present existence after a career of unmerited misfortune, for no other trade ever showed such tenacity of existence as this industry when economical changes made it almost impossible for it to be carried on, except at a loss to all concerned. To assist you to realise the terrible result of the opening of our ports to foreign silks in 1860, the following details are more than sufficient. Before that date the number of looms in five centres of manufacture exceeded 57,000; in the year 1885, these had diminished to 4,400. It may be said that the cheapening of silk has been a boon to at least the female portion of the working classes, but

my own feeling is that they would have been both materially and morally better off if they had remained the makers as well as the wearers of silken goods. Of its importance to us as a nation I need not say more than that France produces over £20,000,000 worth of manufactured silk every year, and exports of that to the value of £15,000,000, a sum which goes far towards paying for her import of corn from other countries. It only requires British energy to be thrown into this matter to enable us to rival and, I trust, excel in every branch of the silk trade as it has in the beautiful plushes and velvets of the Manningham Mill which neither France nor Italy can equal; and the present superiority of France in questions of art is, I think, answered by the display of English designed and woven silks here to-night. When closely examined, this superiority of French art is found to be more apparent than real. Our weak point is that honesty of purpose is always striving after a perfection which is practically unattainable. It is this which renders the designs of our art students so often of little use to the manufacturer, and drives him to either educate his own draughtsman or rely on patterns purchased from abroad. Our students have been so thoroughly well taught the general principles of art and design that, in a manner, they are superior to the narrow requirements of any single trade. They are afloat without direction or purpose, on a sea of experiment, whilst the French designer is safely anchored to his half a dozen orthodox styles. With these he cannot be but safe, and often the only outlet for his energy is the alteration or modification of colour tones in a standard pattern, in order to suit the demands of passing fashion.

There has been of late a good deal of writing and talking about doing something for the silk industries—as if it was a question of charity—and ladies have been asked to show their patriotism by refusing to wear, or use, anything but British made dress silks and furniture brocades, so much so, that the leading ladies in the land have taken up the matter earnestly, and the Ladies Committee of the Silk Association, under the presidency of H.R.H. the Princess Mary, Duchess of Teck, numbers amongst its enthusiastic workers and supporters the leaders of style and fashion; but, unfortunately, in the whole history of trade, we find that something more than an appeal to patriotism is necessary to save from destruction a decaying industry. Fortunately in this case, on every side there is evidence that, instead of failing, it is increasing in importance, and, like our native oak, though slow in growth will be great in maturity.

A step in the right direction has been the formation of the Silk Association of Great Britain, of which Mr. Thomas Wardle is the president; and this is, after all, but the revival of the old system of trade guilds amongst manufacturers for mutual support. In the Middle Ages such a society would be a chartered guild, armed with legal powers, and capable of restraining injudicious competition. But in this 19th century these powers have changed their form, and the Silk Association has broadened its basis by including in its members all those interested in silk, whether producers or distributors, and finally, representatives of the most important class of all the buyers. The Silk Exhibition, a complete success in 1890, was the work of the Ladies' Committee of the Association. Held at the house of Lady Egerton of Tatton, it was successfully carried out by a committee of ladies, who, earnest workers in the two great opposing political parties, sank their differences for a time, and harmoniously together, achieved this great success. In fact, this good feeling of harmony is a characteristic of the silk trade, and, whilst gathering information, I was very much impressed with the kind feeling shown towards each by rival manufacturers. Of this perhaps Mr. Wardle is better entitled to speak than myself, only I cannot refrain from giving testimony to the earnest devotion and unselfish help he has freely given to all classes of silk workers, both before and since the first time I had the pleasure to meet him, when, at the Paris Exhibition of 1878, he practically founded the great industry in the manufacture of "Tussore" silk, in which, I am sorry to say, we have not kept pace with the foreigner, although the raw material is principally supplied from British territory.

Although I have been speaking in defence of machinery, I must admit that my own feeling is against it, as it requires so little human labour, and renders the problem of how to employ our population more and more difficult of solution; yet I cannot but feel that it is inevitable, and, therefore, only wish to see such an increase of trade that the number of people tending the machinery shall more than equal those who now produce the work by hand. One of the causes which will hasten the decay of hand-loom work is the difficulty of finding people to undertake it. The whole tendency of the age is against drudgery of any sort;

and it is only by a long apprenticeship that the hand and eye can be sufficiently trained to produce the fine weaving in the hand-loom. The modern boy will not submit to this apprenticeship. Over-educated for almost any class of manual work in the Board Schools, he is disinclined to take up work where no thinking is required, and to submit to a servitude which, in his opinion, brands him with the reproach of youth, and, in a measure, restricts his freedom. Nor is the effort which is being generally made, and which I see is changing the name of many of our art schools by calling them polytechnics for technical instruction, likely to help in this matter, as the very Act of Parliament which enables the cost of these institutions to be added to our already overburdened taxes, specifies that the practice of a trade shall not be taught, but simply the higher instruction which, when acquired, turns out a possessor of a certificate who has a theoretical knowledge of every part of a trade, but who could not earn a penny loaf by a single day's work with his hands. I am not in any way speaking against our system of technical education as far as it goes, but only wish to warn you that something more than skilful foremen and managers is required, and in my opinion that want was supplied in olden times by the system of apprenticeship.

I have had unusual opportunities of seeing the practice of many arts in various parts of the world, and always noticed that where work was best done was where they thought and talked the least about it. The secret of the woven stuffs of Persia and Cashmere was the five or six years apprenticeship in each branch of the craft; the complete absence of knowledge of any other style in the world; and, last of all, the immunity from changes of fashion, which enabled the people, from father to son, to go on producing the same designs with practically little variation.

The following firms contributed examples of their manufactures and designs:—

George Bermingham, Leek, Staffordshire.
B. Burnet and Co., King-street, Covent-garden.
Collinson and Lock, Oxford-street.
Debenham and Freebody, Wigmore-street.
Gillow and Co., Oxford-street.
Goodyer and Co., New Bond-street.
Helbronner and Co., Oxford-street.
Lasenby Liberty and Co., Regent-street.
J. Nicholson and Co., Macclesfield.
D. Walters and Sons, Braintree, Essex, and Holborn-viaduct.
B. Warner and Sons, Spitalfields and Newgate-street.
Thos. Wardle, Leek, Staffordshire.

There were also examples of silk brocades and dress stuffs from Glasgow, Halifax, and Patricroft, near Manchester.

The examples comprised plain and satin damasks, brocades with various grounds—some with gold and silver figures—broché and brocatelle, tabourettes or striped silks for furniture, figured silks for court and ordinary dress, figured silks for scarves and ties, and specimens of machine-embroidered silks.

DISCUSSION.

Mr. CUTHBERT QUILTER, M.P., said he represented a part of England where silk-weaving at one time was highly prosperous, but he was sorry to say that the county of Suffolk now possessed only a small number of silk-weavers. Even there, however, he believed the tide had turned, and the silk-weavers of Suffolk, although they did not produce such beautiful fabrics as the specimens exhibited, were occupied much more than they were some time back in producing umbrella and other silk of a useful character. There were one or two points in the excellent paper with which he did not find himself in complete accord, being a free trader, but on that occasion they were not met to discuss political questions, but rather to consider whether any combined effort could be made and maintained for bringing back prosperity to an industry in which this country formerly held such a proud position. What he had heard had opened his eyes considerably, as it showed that there were cases in which we could export our manufactures even to France, the land of taste and elegance, as it was generally called; and of all the beautiful specimens before him, his eyes and thoughts had been principally fixed on those which were made to adorn the walls of the *salon* in the Rue de Rivoli, and in the German Palace. If it could be done in one or two cases, why not in hundreds; he would never believe that an English workman could not do anything which the workman of any foreign country was able to do. Give him a little more education, and that sobriety which he sometimes lacked, his insular hardihood, his strength of purpose, and his determination would carry him to the front in any industry in the world. Artistic education had been sadly lacking, but now every County Council was rivalling its neighbour in providing all sorts of technical instruction, and surely the outcome of that must be some practical good to the nation as a whole. Schools of instruction in design, and schools where could be seen all appliances in connection with weaving, were springing up in the North of England, which he hoped would some day rival the great school at Crefeld, where young men could learn everything con-

nected with their art for a comparatively small sum. He was very thankful, speaking on behalf of a large number of workpeople, whose homes were very dark and dreary, wearily watching the throes of an expiring industry, to hear and see that the silk manufacture of England was not extinct, and as representing the descendants of those who left their homes for conscience sake, bringing their beautiful art to this country, he must say that nothing could be more delightful than to take a share, however humble, in bringing back prosperity to the industry in which their forefathers so excelled.

Lord STANLEY OF ALDERLEY said he had hoped to see many well-known people from Macclesfield and Congleton that evening. He had no right to speak on this subject from an artistic point of view, but he was almost as deeply interested in the material prosperity of Macclesfield as if he lived within the borough. He congratulated the silk industry on this excellent paper, and especially on that portion which stated that before the Cobden treaty there were 57,000 looms existing in five centres, and in the year 1885 they had been reduced to 4,400, because there were gentlemen in Macclesfield who maintained, notwithstanding the deserted aspect of the mills, that the town was flourishing, but when they were asked to produce a balance-sheet to prove it they invariably declined. He was also glad to see the merits of Mr. J. O. Nicholson recognised, for he had done a great deal to promote technical instruction; but when he was able to pass himself off as a Frenchman, he should believe that his fabrics would equal the French in excellence of design, but he did not think that would ever be accomplished in the higher branches of the art. Mr. Nicholson and his friends maintained that the silk industry was perfectly flourishing, but Mr. Ben. Elmy, of Congleton, would say just the reverse. The fact was these people spoke from preconceived notions, and those who were originally free traders stuck to their fetish, and would not allow that anything was wrong. But they should remember that the principle of free trade was that we should not tax anything which we could not produce ourselves, and therefore it was perfectly legitimate on the part of the silk industry to claim that that protection which figures showed were necessary to it should be restored; whilst to avoid anything which would imply feelings of bad neighbourhood to France, they should urge the Chancellor of the Exchequer to follow the lines he had already taken in the budget. He had equalised the duty on French wines to 2s. all round instead of 2s. 6d. on sparkling and 1s. on the common sorts, and if he would put a duty on French silks he would do something to restore the prosperity of the silk industry, and if he reduced the duty all round on French wines to 1s. or 6d., that would balance the loss to France, and give us something to bargain with. The Chancellor of the Exchequer was already coming round to the opinion that in order to secure justice from other countries, and to diminish the present severity of the highest tariffs, we should have something to bargain with, and he had threatened Spain, if it renounced the treaty lately made, that he would re-establish the alcoholic standard against its wines. Some persons thought that a duty on silk would raise the price of silk; but that would not be so, for if our own manufacturers secured the market, internal competition between them would keep the price to consumers down. He could remember that, formerly, in the neighbourhood of Macclesfield, silk pocket handkerchiefs were much more common than they were now. The effect of the Cobden treaty had not been to make commoner silks cheaper than they were. All farmers' wives used to like to have black silk gowns, and there was no reason why they should not be entirely produced in England, as design did not enter into the manufacture, the chief thing being solidity.

Mr. THOMAS WARDLE said he must congratulate the Silk Association on the able advocacy it had received from so great a traveller, and so experienced a textile man as Mr. Purdon Clarke. It was very gratifying and satisfactory to find that the Council of the Society of Arts included silk amongst the subjects to be discussed in the Applied Art Section, and he knew of no body which had done so much for the maintaining the arts and industries of this country, and the functions of that Section had never been discharged in so admirable a manner as of late. We had the misfortune to send every year £11,000,000 of our money to France, Germany, Italy, and Switzerland, for manufactured silks, and this had been going on for twenty-five years, so that no less than £270,000,000 sterling had passed from this country to other countries for doing that which our own artisans could and ought to do. The object of the Silk Association was to endeavour, by all means in its power, to discuss such remedial measures as might at any rate reinstate the silk industry in its former proportions; and having served on two exhibition juries in France—namely, in 1878 and 1889—he did not see any necessity why we should go to any of these continental countries for a single yard of silk. He would not discuss the question of free or fair trade, because, even if he had any pronounced views either way, it would not become him, as President of the Association, to discuss such a subject; nor was it the policy of the Association to allow any fiscal considerations to come in, consisting, as the Association did, probably of an equal number of fair traders and free traders. The question was, could not the Association do very useful work outside any such question. At the Paris Exhibition, in 1889, there was such an exhibition of foreign silk as was never before seen. The Lyons section was absolutely magnificent, and no one would wish to deny it, or would wish to deprive the French of the great consideration they deserved of being manufacturers of silk of great taste, and especially

great knowledge of colour; but notwithstanding that, he came back quite convinced that, in the case of silk for upholstery purposes, in colour, in design, and especially in weaving, our English goods were quite equal, and, in some respects, superior to the French. He need not mention the beautiful silks of Austria, Italy, or Russia, or say anything of Germany and Switzerland, because France stood admittedly at the head of all. With regard to dress silks, France probably would be acknowledged to take the leading part even to-day, but he was not disposed to admit it with regard to fabrics especially adapted for domestic uses, other than those for dress. With regard to the price of manufacturing silks, it was a fallacy, as had been stated, to consider that the English makes were dearer. Very recently he went into one of the principal retail establishments in London, where he was told that English silks could not compete with foreign; and he was much astonished to find, on being shown two samples—one of which he had with him—that it was priced at 28s. per yard retail, 60 inches wide. It seemed an astonishingly low price for silk of that character; and he was also shown, at the same time, a brocatelle from Spitalfields, pretty much about the same substance, the price of which was about £4 a-yard. He felt sure that there was some reason to explain the difference, and asked to be allowed to examine it. He examined both, and found the Spitalfields to be absolutely pure silk, both warp and weft; but when he came to examine the other, he found there was not, strictly speaking, an atom of silk in it. It might be called silk, and was sent into England in great quantity as silk; but it might be useful for ladies to know how easily they might be deceived by prices with regard to such goods. The warp was spun silk, which was known to be manufactured from waste, and of course was much less expensive than that reeled from the cocoon. The weft consisted partly of cotton, but chiefly of Tussore silk, and it was a remarkable example of the utilisation of the wild Indian and Chinese silk. The price, roughly speaking, of thrown Italian silk to-day undyed was about 20s., the price of the raw Tussore in London was 2s. 6d., and the spun silk, of which the warp was composed would be about 8s. or 10s. a pound. He showed the sample to an English manufacturer that morning, and he said that he could easily make silk of the same materials for 15s. a yard. It was very desirable that ladies should be allowed to know what they bought, and the object of the Ladies' National Silk Association was not to ask ladies to wear English silks only, but to ask drapers and distributors to allow them to know what they were buying, and whether they were buying pure silk or weighted silk. If they found the silk was suitable to their wants, and as good as that from France and other countries, they would naturally give a preference to the English. There was no desire to help on the silk industry of this country in a patronising sense, but simply that ladies should be allowed to know what they were buying. Last year the Association received a great shock from one of the leading distributors who, in the *Times* newspaper, said the "English people did not care for English silks because the foreign were better all round." Without going into details to disprove it, which he had fully done at the time, he was quite certain that, with regard to manipulation, colour, and dyeing, many of the silks now shown could not be excelled in any continental country, either in cheapness, durability, or purity of dye. This is particularly so with patterned silks of the lighter and less costly kinds, and also with plain silks, and it is high time that this important fact should be generally known by ladies, who had for years been grossly deceived in this respect by statements to the contrary made by importers of foreign made silks. The interesting and numerous exhibits around the walls fully bore out this. The principal utility and aim of the Silk Association of Great Britain and Ireland probably lay in what it was doing to promote technical instruction. They had in Coventry one of the most useful weaving schools in England, presided over by influential members of the Council; there was another at Macclesfield, and another at Leek, which in its various branches numbered nearly 500 students. Mr. Quilter had been too modest to speak of his own efforts in West Suffolk; being not only member for that division, but a member of the County Council, he had devoted a considerable sum of money to aiding in the development of the industry in Sudbury, Glemsford, Haverham, and other districts, and he had heard lately, from a Sudbury manufacturer, that the trade was looking up, and they hoped before long, with the aid of better technical instruction, to recover their lost ground. In Manchester, the Council of the Silk Association was at work trying to found a central institution for higher technical education in throwing, weaving, dyeing, and finishing, so that the sons of our manufacturers and managers might go there and receive such an education as was given at Crefeld. A journal, entirely devoted to silk, would soon be established, and he had received from the Secretary of H.R.H. the Duchess of Teck a letter, saying he was desired to express her Royal Highness's regret at not being able to be present that evening, and how much she regretted what she feared must be the injury done to the reviving silk industry by the recent national bereavement. He knew no one in England who had taken a deeper interest in the revival of the industry than H.R.H. the Duchess of Teck, and she was very pleased, in view of that recent anticipated event, which then promised to be so happy a one, that the whole of the silk for the royal wedding was to be produced by English looms.

Mr. Lasenby Liberty said it had been most interesting to follow Mr. Wardle with reference to the two examples of silk he had been comparing. He failed, however, to gather whether, in Mr. Wardle's opinion, it would be desirable for the

British manufacturers to adopt the examples set them by their French competitors, that is, to compete with the foreign manufacturer by producing silken fabrics composed of the less expensive materials which Mr. Wardle found in the brocade to which he had called attention. At first he understood Mr. Wardle to say there was no true silk whatever in the French fabric, and, subsequently, that though none of the more expensive yarns were used, the fabric was, as a matter of fact, "all-silk." Mr. Liberty believed the more general introduction of the Tussore silk referred to would secure a two-fold advantage, for besides lending an element of greater durability, it fostered an important industry in which our fellow subjects in India were largely interested. Personally he felt, though it was most necessary to assert our artistic and manufacturing superiority in the Spitalfields and other high-class brocades, it was not desirable to limit the British silk industry exclusively to the more costly goods, as comparatively there could then be but few purchasers, and the trade would be artificially cramped by an altogether unnecessary barrier placed in the path of the expansion and prosperity which could otherwise be attained. He believed the object of the Silk Association should be to secure for the British industry as wide an area of enterprise as possible, provided good and honest materials are used, and an intelligent selection of designs and colours made; and he was strongly in favour of inviting the public to share in every advantage and economy in the manufacture. He might add a recent instance within his own knowledge, in which an English house had been supplying English-made silks to Paris and other Continental centres. They had not extended their operations very far, but the sale was gradually increasing, and it had excited a certain amount of antagonism in Paris, as evidenced by anonymous postcards being received, threatening with dynamite. That unpleasant episode might, he thought, be taken as a compliment to the merits of the English silk manufacture. With regard to the former use of silk handkerchiefs in the neighbourhood of Macclesfield being more general than at present, he had some doubt whether it depended so much on questions of free or fair trade as on a change of fashion, and the now almost total extinction of the habit of snuff-taking.

Mr. BENJAMIN WARNER, speaking as an old Spitalfields silk manufacturer, said he considered the very interesting paper just read would do a large amount of good. He agreed with Mr. Purdon Clarke in saying we should endeavour to increase the practical knowledge we have in this country. In France, the State paid professors to give lectures in the manufacturing districts, and youths went through a thorough course of training in the theory of weaving, fitting them to occupy the position of manufacturers. It had been the fashion of late years to encourage everything foreign, resulting in many of our best men being driven away to enrich other countries. When he was a youth, the Spitalfields silk trade used to provide a living for about 100,000 persons, now it provided a precarious living for only very few. There were thousands in the east end of London who had no regular employment of any kind; the strongest got occasional work at the docks, and their families were assisted by the benevolent, but in his opinion the wisest and best form of charity was to give employment to the people, and unless they were better employed the nation must suffer. At the present time there was a sign of weakness; a few days back he received a paper from the London Chamber of Commerce, asking for replies to questions. The first was—"Did he approve of the £1 note?" to which he replied "Certainly not;" to the second question, "If he did not approve of £1 notes, would he suggest in what way the gold could be kept in the country?" His answer was, "Encourage home productions of every kind." And from an experience of more than fifty years, he knew of no better employment for the working classes than weaving, which, being an indoor employment, was good for both sexes. The delicate treatment which silk required had a refining influence upon those employed, and amongst the weavers, types of men were found of whom any nation might be found. The Silk Association had done some good, more especially the Ladies Committee; they had given the manufacturers substantial encouragement, and he believed that they and Mr. Purdon Clarke would have the satisfaction of knowing that their efforts would bring a blessing to the homes of the working classes.

Mr. J. H. DONALDSON said he was obliged to dissent from some of the views expressed by Mr. Clarke. While he much admired the paper, and felt that it would tend to benefit greatly the class he desired to help, there was nothing to be gained by attempting to conceal from ourselves the fact that there were certain things which the French could do with greater dexterity and skill than we could. There was a sensibility of hand possessed by French workmen by no means common amongst English workmen. Long years of encouragement, the peculiarities of race, natural taste, and, possibly to some extent, the influences of climate, had resulted in producing a workman of great acuteness of mind, of much intelligence—far, he thought, in advance of the average English workman. The French workman had ideas of fashion, taste, elegance, and refinement constantly before him, and, having art all round him, he had brought his natural aptitudes to the development of art in relation to his work, and the result was that you had, for the production of the highest class of silk, a very superior kind of person to the average English workman. In 1889, he went round the Lyons Court of the Paris Exhibition with Mr. Wardle, and well remembered the enthusiasm with which that gentleman spoke of the splendid works there displayed. It must be admitted, even by Mr. Clarke, that nothing

had yet been produced in this country comparable with the best work there shown. They could well understand why that was so; there had been men of the higher class in France who appreciated these beautiful things, and, naturally, where there was the demand, the supply followed. It seemed to him only prudent to recognise these facts; not to attempt the production in this country of the highest class of work, but to adopt rather the suggestion of Mr. Liberty, and produce a medium class of work, thoroughly good of its kind, which could be made use of by persons of comparatively limited means. No doubt, as machinery was perfected, as education advanced, and the people became more intelligent, there would be a nearer approximation to the high-class work produced in France; but you might as well attempt to produce wine in England as an article of commerce, as to produce the very highest class of silk work, such as was produced in France. Why did we pay eleven millions for French silk, and why did America, Russia, and all the great nations elect to go to France for their principal silk supplies, except because the highest class of work was to be found there. Polytechnics, to which Mr. Clarke had alluded rather disparagingly, were doing a very great and valuable work in developing the intelligence of the working-classes. The system of apprenticeship prevailed much more in France than here, it was a thoroughly organised system there; but here the habit of apprenticing boys for five or seven years had nearly disappeared, especially in London. Consequently, there was not that rigid supervision and intelligent direction over the youth which operated so largely in France, and resulted in the production of a splendid and capable workman. They should seek by every means to extend the system of apprenticeship, and induce masters to employ as many boys in their factories as the men would permit, such a system being the best security for the production of efficient workmen.

The CHAIRMAN said, although he believed Lister and Co. to be the largest silk manufacturers in the world, he knew very little of silk manufacture; his *rôle* had been that of an inventor, of technical knowledge he had little. He agreed that if the silk problem was to be mastered, it would be through technical teaching, but though that would do much it would not do everything. It had been neglected in England for many years, and we should have been marvellously more forward if we had thought about it earlier; but somehow or other Englishmen always thought they could beat the world without troubling to learn. Now they were finding out that they would have to learn how to design, to dye, and to do everything else. Still it was a peculiar feature about Manningham that there was not, as far as he knew, a technical taught person about the place. He himself was brought up for a clergyman, and learned Latin and Greek, and nothing else, but somehow he turned to that for which he was naturally fitted—invention. His first efforts were to beat the whole world in wool, and he created in ten years, from 1845 to 1855, the largest wool concern ever seen. He had five establishments in England, three in France, and one in Germany. Having exhausted the field of invention there, he turned to silk; he had no knowledge of it whatever, but he saw there was a field in silk, and set to work by little and little, one thing after another grew, until Manningham became the vast concern it was. Their dyers produced about as fine colours as any in the world, and yet he believed they had not one who had not learned simply by rule of thumb. That only showed that if England could do this without technical education, what might she be expected to do with it. He did not suggest that they were any the better for not being taught; on the contrary, if we could beat other nations as we were, we could beat them vastly better when properly trained. In design, colouring, artistic knowledge, the assimilation of colours, and all that sort of thing, England was behind. Of course there were certain other difficulties, and he might easily be led into delivering a fair trade lecture, especially as he had one prepared to deliver to an audience of 2,000 or 3,000 last week, who would not listen to him, from ill-will caused by the strike; but they were not met to talk about fair trade except in one point of view. He must say there was one thing which made him exceedingly angry. At Manningham, at that moment, they could beat the world, but half of the machinery was covered with dust, and 2,000 workmen were on the street, and that simply because America put on a duty of 100 per cent., in order to exclude English silks; they tried to do it with 75 per cent. and failed, but they managed it with 100 per cent. In Germany, which had a magnificent technical school at Crefeld, they would not allow English untechnical goods to enter. They came here and sold their goods free, but when Englishmen went there, they said, "Oh, no; we are technically instructed here; and we have learned, if you beat us, to shut you out; but when we can beat you, we come over to London, as the best market." That was very provoking; and he could not understand why the English did not learn wisdom. Everyone who had read the history of the silk trade knew that at one time it was very flourishing in England, and they all knew why it did not flourish now. The year 1860 made the finish of it; it never recovered that blow. He concluded by moving a cordial vote of thanks to Mr. Purdon Clarke.

The vote of thanks having been carried unanimously,

Mr. PURDON CLARKE said he would confine himself to replying to what had been said by Mr. Donaldson, because he did not consider that Englishmen should be discouraged in trying to beat the French. We had proved our superiority in many other things, and he was confident, from what he

had seen, that we should be able, if not to beat them, at any rate to rival them in the higher arts. Mr. Donaldson had explained the matter himself, when he spoke of the opportunity France had had. The specimens he had shown that evening were produced by a few manufacturers, working for a very limited market, but France was making for the whole world; and in the fine arts experiment and practice were factors as valuable as that intangible quality known as good taste. France had the advantage not only of that great market, but ideas and demands were sent in from the whole world, and they were all worked up in the Lyons factories. If Spitalfields were placed for a few years in the same position, we should soon level up, and if we had ten years, we would leave France behind. It was perfectly absurd to tell the countrymen of Flaxman, Turner, and Alfred Stevens that refinement in art must be left to the French. He was rather sorry that he had introduced political matters, but that was more the fault of politicians who meddled with questions of commercial expediency which they were either incapable of understanding or did not wish to. He felt very strongly that something should be done to secure a more favourable tariff for the entry of our silks to foreign countries, especially as France was re-adjusting the duties in an adverse manner, and, as Lord Masham had just informed them, the duty on some sorts of silk goods had been raised 100 per cent. in America. Perhaps the solution was to be found in a remark from one of the most important distributors, a Scotchman and a free trader, who said that, whilst he had always been a free trader, and would remain one, he sometimes thought that a little vindictive retaliation might be useful, when other countries imposed prohibitive duties, and that, at the present time, something of the kind was necessary to help our silk manufactures.

Sir George Birdwood writes as follows:—I deeply regret having been forced, by a severe accession of neuralgia, to leave the Society's Lecture-hall before the discussion on Mr. C. Purdon Clarke's paper was half over, and hope that the following remarks which, had I been present, I should have made in reply to Mr. Hunter Donaldson's despairing speech, may not be too late for publication with the official report of the proceedings on the occasion. Confining my defence of the natural artistic aptitudes of our English manufacturers to the proofs afforded within the range of the special manufactures treated of in Mr. C. Purdon Clarke's paper, I will merely say that having been afforded the opportunity, by Messrs. Collinson and Lock, of closely watching for twenty years past the growth and development of the lovely silks and brocades associated with the name of this firm, some of the best known of which were exhibited in the Society's Lecture-hall, I have long been convinced that for stateliness and grace of design, richness and delicacy of colour, and exquisite execution, and general originality of treatment, they are equal to the finest productions of the famous looms of Lyons. I recollect when Messrs. Collinson and Lock first gave up having their silk stuffs manufactured in France. They wanted to reproduce, in large quantity, for the late King of Bavaria, a fine old brocade of the last century, and the price asked by the Lyons weavers was so enormous that they resolved to have the work done at home, and, after many abortive trials, with the successful result seen in the beautiful brocade shown by them under the name of "Malta," and sold by Messrs. Collinson and Lock at about half the price a Lyons silk manufacturer would charge for it. This was in "the seventies," and since then this pattern has been produced in every combination of colours, and hung in many historic houses, including the Imperial castle of Charlottenburg. Next, they brought out a number of pure silk damasks, dyed by Mr. Thomas Wardle, and sold them at the price of fairly good "tapestry." They are dreams of exquisite colouring, but substantial as "cloth of gold, of tissue." More recently, they have been systematically reproducing the noblest designs of the Renaissance period to be found in textile fabrics, and in novel combinations never before attempted—gold brocades, and silver and gold brocades, and brocades of mixed threads of gold and silver and silks, and with effects of colour worked out entirely by Mr. George J. S. Lock, and peculiar to himself. They were hanging on the Society's walls last Tuesday; but it is at the Lyceum Theatre, in Mr. Henry Irving's mounting of *Henry the Eighth*, that they are to be seen in all their splendour and glory; and as I have referred to Mr. Henry Irving, let me add that no one has done more than he to promote the revival in our generation of the noble silk industry of England, so true is it that, as Cicero has said, all the arts are connected together:—"Omnes artes, quæ ad humanitatem pertinent, inter se continentur." Mr. Hunter Donaldson must have seen these things; and seeing them, should surely have perceived from them that in this country we have the means of accomplishing anything and everything that could be attempted in the way of artistic silk weaving, provided only the resources at our command are directed by knowledge, taste, and the high courage that can peremptorily and resolutely "damn the expense."

Miscellaneous.

IRRIGATION OF ORANGE GROVES IN JAFFA.

The United States Consul at Jerusalem says that the orange groves, and their system of irrigation, though they have been greatly extended within comparatively recent times, have unquestionably an origin of great antiquity. The area of land unde

irrigation at Jaffa would exactly include the space occupied by its orange groves, being nearly one-third of the cultivatable ground belonging to the community—that is, of 9,000 acres of cultivatable land, about 3,000 are under irrigation. The orange and the lemon are the chief crops; but other fruits, such as citrons, limes, peaches, apricots, grapes, pomegranates, and melons, and all the ordinary garden vegetables, are also produced in abundance, and of fine quality. The vine especially is of late receiving much attention, and within the last few years extensive vineyards have been planted. Neither the vine nor the olive, of the latter of which there are many groves, requires any water other than the usual rainfall. The superiority of the Jaffa orange is world-renowned, whether its size or flavour is considered. In an average season, oranges and lemons, together with other fruits and vegetables, to the value of £67,000, have been exported from Jaffa, and in addition to these there is an immense home consumption. The sources of the water-supply are wells, which are fed by underground springs. The engine in use for raising the water is, in every case, without exception, the so-called *bajara* or *bayara*, a wooden machine of the most simple construction, driven by horse or mule. Its principal parts are a whim beam or capstan, with horizontal wheel attached, moving a vertical wheel connected by shaft with a third wheel, which carries a chain holding reversible buckets. A pole inserted in the whim beam is fastened to the horse or mule, and the whole machinery is set in motion, the wheel with buckets revolving in the well, dipping up the water and emptying it into the conduit or tank. The tanks are usually close to the wells, and are cemented basins built of stone. They are filled during the day, the water being distributed from them through the various channels during the night, in order that the loss by evaporation may be reduced to a minimum. There are about 700 of these *bajaras* at work in Jaffa, and the system of water distribution, being entirely under private control, is governed by neither law nor regulation. The quantity of water used per acre during the season of twenty-three weeks is 2,300 cubic metres, at a cost of 10d. to 1s. per diem. Thus, for instance, the average expense of irrigating an orange garden with an area of five acres, would be about £38, and the value of the crop may be estimated at from £100 to £150. As to the antiquity of the system of irrigation, the close resemblance of the *bajara* to the Spanish *noria*, has induced many persons to imagine that it was introduced into Jaffa at some early period from Spain, but as the family likeness of these wheels to the ancient Persian wooden water-wheel is equally great, and as the orange tree was found in Palestine by the Crusaders, in the 11th century, the actual system of irrigation, says the United States Consul, might well belong originally to Palestine, or may have been introduced from Persia. Owing to the peculiarity of the climate, the orange groves are obliged to be watered during the summer months, or, rather, during the dry season, when no rain falls, that is from May till October, or November. The rainfall in the winter months, that is, from November to May, varies from 17 to 30 inches. The phenomenon of the "air cushion" is seen in Jaffa, says Consul Gillman, to perfection. Before a rain sets in, it generally takes several days of preparation before the result appears. Great clouds roll up and cover the heavens with their dense masses, but they attempt in vain to discharge their contents, or, if they do succeed in dissolving, the thirsty atmosphere drinks up the moisture before it even reaches the earth. And this must continue till the intervening strata composing the "air cushion" are sufficiently saturated to permit the rain to fall through, which then occurs in a violent and often injurious downpour.

METEOROLOGICAL CHANGES IN FRANCE.

Mons. Flammarion, the French astronomer, has recently been directing attention to the climatic changes in France. According to the United States Consul at Bordeaux, he states that, from actual figures obtained within the past six years, the temperature of Europe has been falling. France has been suffering for a long time from an excess of cold weather, the thermometrical readings at Paris having been one degree Centigrade below the normal height. Other readings show even less favourable results. The fall is more noticeable in the spring than during other periods of the year. Similar phenomena are recorded in Great Britain, Belgium, Spain, Italy, Austria, and Germany, while the really cold countries, such as Denmark, Norway, Sweden, and Russia, have enjoyed, during the last four years, a temperature slightly above the average. In the days of Philippe Auguste, in the 13th century, the wines of Etampes and Beauvais, were the favourite beverages at court. Henry IV., a pronounced *bon vivant*, frequently expressed his fondness for the product of the Suresnes grape. At the present day, there is not a vineyard of importance north of Paris; and as for the *petit vin* now made at Suresnes, it has become only the drink of the poorer classes. In the middle of the 16th century, Macon was celebrated for its muscat wines, whereas the muscatel grape, at this moment, can scarcely be made to thrive there. Ancient chronicles mention the cultivation of the vine in Northern Brittany, where now even apples are not plentiful. Again, it is to be remarked that trees which once flourished in the north of France, are at present found only in the extreme south, and a considerable number have disappeared altogether. Languedoc no longer grows the lemon; there is not an orange left in Roussillon. The Lombardy poplar, so familiar and picturesque an object in old French line engravings, is now nowhere to be found on French

soil. These are facts which, says Consul Knowles, putting statistics out of the question, serve to illustrate the changes wrought by temperature in the great fruit-producing country of France.

Correspondence.

THE OPIUM QUESTION.

Having been employed for about twenty-five years in the Province of Guzerat, in which the habit of opium eating is notoriously prevalent, I can state from personal experience that, so far from that habit being injurious to the well-being of the people, morally as well as physically, the peasantry of the province, and especially those of Kaira, are the finest, most industrious, most skilful in agriculture, and the most law-abiding that we have in Western India. There can be no doubt that if by any means the habit could be put a stop to, the people would be forced to resort to some other stimulant or narcotic to counteract the malarious effects of the climate. The alternative would be either the frightful produce of hemp, in the shape of *bhang* or *hashish*, under the influence of which, it may be noted for the information of the anti-opium agitators, the crime of running "a-muck" is invariably committed, or the drinking of the fermented juice of the palm. I should like to draw attention to the comparative results of opium eating and intoxication from this spirit, as shown by criminal statistics. Taking the whole population of Kaira—notorious for opium eating —and that of Tauna (Phána), where the palm abounds, for the year 1890, the last year for which statistics are available, I find that, whereas in the former one in 334 was charged with crime of some sort, in the latter, one in 159, or, say double the number, was so charged. These statistics are amply borne out by my experience as Police Commissioner in both these districts. I can, in fact, only recollect one single instance in which I saw a man at all the worse for eating opium. This was in the case of a Rajpoot official, who appeared half-dazed, and unable to answer questions intelligently. He, however, left my tent for a minute, and came back, after taking his little dose, which acted as a pick-me-up, as brisk and intelligent as anyone could wish to see.

Mr. Batten, in his paper, talks of the difficulty attending the establishment of a frontier line of 2,000 or 3,000 miles. This probably refers only to the old preventive salt line, as that length of line would probably not suffice for Guzerat alone, in which British and Gaekwari villages are greatly intermixed, especially in those parts of the country in which the poppy is most successfully cultivated. Where such is the case, it would be simply impossible to put a stop to the smuggling of an article like opium, of which a quantity sufficient to last a moderate eater for a year, at the rate of 10 grains a day, can be easily carried in one's pocket. The anti-opium party are strong on the point of putting a stop to the growth of the poppy. They are probably not aware that such has been the policy in Bombay, ever since we took possession of the greater part of the country rather more than 70 years ago. This has, however, not had the effect of putting a stop to the practice of opium eating, as they imagine it would. The Indian Government have been wise enough not to attempt the insane task of "expelling nature with a pitchfork," and have supplied good opium for consumption through licensed vendors, and have thus, I have no hesitation in saying, saved the people from decimation. If you cannot by law prevent the use of opium, or some kind of intoxicating stimulant, in India, does it not stand to reason that the better policy is that of controlling it as far as practicable? You cannot put a stop to the drinking of beer and spirits in England; would any Government sufficiently insane to do away with the licensing of public houses and abolish the tax on drink remain long in power?

But the greatest argument in favour of the continuation of the present system in India lies, as I have already stated in a letter to the *Times*, published about two months ago, in the impossibility of preventing the growth of the poppy in the native States everywhere intermixed with British territory. Were England to double her national debt, with a view to compensating those States for the abolition of its legal cultivation, I maintain that with the whole people in opposition to us, we could no more carry out the policy than the Government of China are now able to do. Under all these circumstances, were it not for the evident illusions, arising from the deaf-adder like proceedings of the Anti-Opium Society, and the mistaken sincerity of some of its members, the arguments they bring forward against the opium system in India may be designated by no worse than the appellation of childish. If they are in want of a reasonable policy, let them agitate for the adoption of the British system in all native States by the rulers of those States. Treaties to this effect were entered into with those in Guzerat on the assumption of British rule there, and might probably be carried out without much difficulty elsewhere.

A. Rogers,
Late Revenue and Police Commissioner in Guzerat.

ENGLISH TRADE AND COMPETITION.

My friend, Mr. Ewing Matheson, has dealt with the subjects of exchange and trade, which are of particular interest to the Society of Arts. As Mr. J. Biddulph Martin and himself say, it is not easy always to get at the exact facts of matters so complicated. It is true the Germans have long carried on a fierce competition, but whether they have so fully

succeeded, and whether the English are such fools as writers on the subject suppose, Mr. Matheson is inclined to doubt.

Mr. Matheson knows that he is stating what is correct, when he says (p. 508) that it is not all profit to the German. There are countries where there is no English or American merchant, and where the Germans have stepped in. On a little inquiry, we should find that there are big houses here which have no longer any trade in the country, but which have, after twenty or thirty years, large sugar and coffee estates belonging to them, and hanging on their hands. One curious thing is that some of these merchants are of German birth, because the great houses in London include Hamburghers and other Germans, who have preferred an English habitat for carrying on their foreign business, and these are among the parties incriminated as being inferior in enterprise to the Germans.

A young German clerk sets up as a shopkeeper in a country, and he readily receives support from Germany in the supply of goods, and in obtaining credits. He carries on a direct trade with the storekeepers and planters, and does a very good business, and goes ahead. By-and-bye comes the coffee-borer, a civil war, or some other plague, and the whole trade is stopped. His German friends are locked up, but they are "secured"—secured with a vengeance by coffee estates. Of this process in time they get sick. The London houses know it, and it is not want of enterprise keeps them out of the market.

Another chance for the young German is this. In the corrupt states of South America the goods are smuggled by connivance of the local houses and the Customs directors. This is business which the English and American houses will not do, and, of course, they cannot compete with local houses. A few years ago there was not an English or American house left in Mexico on this account.

The young German clerk goes in for contraband, and does well. Some day an opposition political party will get into power, and put the Customs directors and merchants in jail, and take measures to extract as much of the spoil as they can.

The German shopkeepers all over the world do a large business in bogus English and French goods at low prices, with forged trade marks, and which are sold to native shopkeepers in fraud.

A large resource to the German dealers is to obtain goods from German manufacturers, who get no returns, and are plundered to an enormous extent. As Mr. Matheson intimates, the English manufacturer does not show a readiness for this kind of business nor the requisite enterprise. He therefore prefers (p. 508) to leave to merchants here to look after the money to be paid for his goods, instead of losing.

This explains the late Foreign-office correspondence, where a London house declined to supply goods to a Bulgarian house in Sofia, except for cash in London. On any other conditions they had no remedy for their money. H.M.'s Consul need not have been much surprised at this result. Another house refused to supply a less consignment than 150 tons of slates, to the great surprise of that functionary.

A large branch of German and Belgian enterprise, with which Mr. Matheson is acquainted, and which is not so profitable as it assumed, is the sale of metal, engineering and other goods in this market, at lower rates than the local prices, for the purpose of getting money to work the foreign factories.

The Lyons silk manufacturers also do something in this way. As they cannot sell locally under the trade "scale," when they want money they send to this market, which is the slaughter-house of the world, and raise money here. The statistician has some interesting figures of so many goods and so much value, but which do not represent the real nature of the transaction, which is a loss for France. Some of the goods are sent abroad, so as to compete at under prices with French silks. Board of Trade figures do not always represent commercial facts.

Where the business is carried on by mercantile credits, English commercial travellers do not go, because all goods are purchased by the English house, and this gives one of the commissions on the business.

Scattered over the world is a large body of French traders, who deal in articles de Paris, French silks, &c., and for which they receive ready-money, transmitting it with the orders to the relative or correspondent in France, sometimes in advance. No French traveller stands a chance there. In some places specie is remitted in groups, in some bills of exchange, and a large amount of the imports of specie by steamers is on French account. They sell genuine articles and get their own prices. The Catalan shopkeepers are again doing a large business of the same kind, and so are the Genoese and other Italians.

The smaller houses rarely deal in produce for export, though in the present day the numerous steamers that call give facilities. Produce goes mostly to the English houses, unless it is a special article for the French, American, or German market. In many cases the produce goes in the nature of things to the English houses, as they make advances on crops, and the produce may be shipped to Havre, Hamburg, Bremen, Rotterdam, or some other port.

The produce houses generally have in their hands the bill market and the sale of bills, regulating the rate among themselves, including all the English and foreign houses. A well-established house makes a separate profit on the drafts that are sold, and sundry commissions.

One little matter that is known in connection with certain places is liquidation. The local houses periodically wind up, leaving the foreign creditors minus. Calcutta, Constantinople, and Smyrna, have carried on the business of liquidation for above a century.

Wherever there is a Consular Court, and there are plenty of these now, the English merchant has no

remedy against his local debtor, who is under the protection of some consulate, and his consul stands by him against the foreign claimant.

In many other places there is no remedy if the judge is godfather or *compadre* with the defendant.

These are a few cases in support of Mr. Martin and Mr. Matheson that the incidents of trade are rather more complicated than appears on the surface, and not wholly dependent on commercial travellers or price lists. It is not the business of merchants to state their course of trade for the amusement and instruction of writers in newspapers.

Of late there has been an enormous expansion of trade in the world, and many countries are getting a share of this, but we cannot relax our exertions.

HYDE CLARKE.

CHICAGO EXHIBITION.

Mr. G. N. HOOPER writes:—The American people invite all the world to a great festival *and competition* at Chicago. They do so not as philanthropists, but champions in a struggle for supremacy in manufactures and commerce. As evidence that they are in earnest, and that this effort is no child's play, they incur a vast expenditure, they plan and build vast and handsome structures, not for use only, but to please the taste. There are to be amusements and pleasures as well as serious business, and still more serious adjudication of rewards.

The stakes are heavy, but the gains and losses may be proportionately heavy. But, to make the gains certain, and the losses unlikely, they have sent an able Commissioner to repeat the general invitation, and to make it almost personal.

The collection of foreign exhibits is undertaken under immense difficulties, with an almost (and intentionally) prohibitive tariff. That tariff is not of exceptional advantage to the United States, for under it the rivalry of American shipping has been removed, while that of our country has been immensely extended.

In these days, isolated individual exhibitors, in many cases, are at a great disadvantage, for without previous arrangement with others, they may chance to exhibit large quantities of similar goods, create needless and reckless competition and profitless trade, while other goods are not shown, and trade is thereby lost. By a carefully selected exhibit of the *best goods* of the *best makers*, a good impression can be made on visitors, and advantages directly come to those whose goods are not shown, as well as to the exhibitors themselves.

The Institute of British Carriage Manufacturers is endeavouring to arrange for a very select exhibit of twelve carriages of the best London, provincial, Scotch, and Irish makers, each to show some special carriage for which they have a reputation. Such an arrangement has been worked by French and Belgian makers, and if our very free institutions permit such joint action for mutual support and advantage, it appears to me to be the best for such occasions, where heavy expenditure and disappointment are frequently the lot of those who act without looking closely to ascertain the best ways and means to accomplish the end they desire to attain. Our ancestors shed their blood freely, and spent millions of treasure to extend British influence and trade.

Times have changed—and we are now invited to a peaceful and commercial struggle, where time and money have to be spent to hold our own; but these sacrifices are trifles when compared with those of our ancestors, who did the fighting years ago, and formed the commerce that our generation now enjoys.

Notes on Books.

A FIRST BOOK OF ELECTRICITY AND MAGNETISM: for the use of Elementary Science and Art and Engineering Students, and general readers. By W. Perren Maycock, M.Inst.E.E. London: Whitaker and Co.

This work is intended as an introduction to the ordinary text-books of the subject, and covers the syllabus of the elementary stage of the Science and Art Department. The first part is devoted to magnetism, the second to electrokinetics or electricity in motion, and the third part to electrostatics or electricity at rest. Questions are attached to each part, and a list of apparatus required is added at the end of the book.

THE PRACTICAL TELEPHONE HANDBOOK AND GUIDE TO THE TELEPHONIC EXCHANGE. By Joseph Poole. London: Whitaker and Co.

In a volume of convenient size Mr. Poole has succeeded in giving a large amount of information respecting the telephone and its latest developments. The various instruments in use are fully illustrated, as well as the necessary apparatus. The special Exchange systems are also explained. The book has on the whole 227 cuts.

ENCYCLOPEDIE SCIENTIFIQUE DES AIDE-MEMOIRE. Edited by M. H. Leauté, Membre de l'Institut. Paris: Gauthier-Villars et fils.

Résistance des matériaux, 1892. By M. Duquesnay.

Distribution de l'électricité par installation isolées, 1892. By R. V. Picou.

Transmission de la force motrice par air comprimé ou raréfié, 1892. By Al. Gouilly.

Etude expérimentale calorimétrique de la machine à vapeur, 1892. By Professor Dwelshauvers-Dery.

The above four volumes all form part of the technical series, published for the use of engineers

and contractors under the title of the *Encyclopédie Scientifique des Aide-Mémoire.* Each book contains a collection of formulæ, tables, and other information relating to its own subject. That of M. Duquesnay has a bibliography of French books and memoirs on the subject of the strength of materials, strains, &c. All the treatises appear to be of a thoroughly practical character.

HANDBOOK OF THE UNITED STATES. Edited by Moses King. London: Osgood, McIlvaine, and Co.

A very full and complete guide-book to the States. Each State has a separate section to itself, giving its history, statistics, description, accounts of the principal cities, &c. These are all arranged alphabetically. There is a map of each State, and the book is very fully illustrated throughout, there being 51 coloured maps and 2,600 illustrations.

THE ADVANCED CLASS-BOOK OF MODERN GEOGRAPHY: PHYSICAL—POLITICAL—COMMERCIAL. By William Hughes and J. Francon Williams. London: George Philip and Son.

This volume contains a full account of the various countries of the world, in which particular attention is paid to the industries and trade of the countries, as well as to the physical properties and political condition. The introduction deals with the essential elements of the science of geography, and contains an account of the geographical distribution of man, and of the necessaries of life.

PYE'S SURGICAL HANDICRAFT: A Manual of Surgical Manipulations, Minor Surgery, and other matters connected with the work of House Surgeons and Surgical Dressers. Third edition, revised and edited by T. H. R. Crowle, F.R.C.S. Bristol: John Wright and Co.

The author states that his aim in producing this book has been to draw special attention to the manipulative side of surgery, and to impress upon students that, although surgery is becoming more scientific day by day, yet that surgeons can never cease to be handicraftsmen. The subject-matter of the book is treated under 10 sections—(1) On the arrest of hæmorrhage; (2) apparatus for restraint and support (bandages, splints, &c.); (3) of fractures; (4) wounds, ulcers, burns, &c.; (5) cases requiring prolonged or mechanical treatment; (6) emergencies, such as drowning, poisoning, &c.; (7) anæsthetics; (8) extraction of teeth and management of aural cases; (9) minor surgery; (10) preparation of patients for operation, &c.

Three chapters are contributed by other writers: that on the administration of anæsthetics by Joseph Mills; that on the extraction of teeth by H. Howard Hayward; and that on the practical management of aural cases by G. P. Field. The book is fully illustrated.

EPITOME OF MENTAL DISEASES: with the present Methods of the Certification of the Insane, and the Existing Regulations as to "Single Patients," for Practitioners and Students. By James Shaw, M.D. Bristol: John Wright and Co.

The title of this book sufficiently explains its contents; but, it may be remarked, that one chapter is devoted to an index of symptoms with the mental diseases in which they occur, and that another contains an index of mental diseases, with their synonyms and symptoms. The last chapter is devoted to the consideration of legal regulations and forensic psychiatry, and contains forms of certificates, orders, &c., now in use, and a statement of the legal tests of insanity, and legal responsibility of the insane.

SOLUTIONS. By W. Ostwald, translated by M.M. Pattison Muir. London: Longmans, Green, and Co.

The translator points out that a complete account of the facts relating to solutions, and the theory drawn therefrom, is only to be found in Professor Ostwald's "Lehrbuch der Allgemeinen Chemie," and he has therefore translated the portion of that book which relates to the subject, and published it as a substantive work. The author has revised the translation and made such changes and improvements as he considered necessary. The subjects of the various chapters are as follows:—Solutions in gases, solutions of gases in liquids, solutions of liquids in liquids, solution of solids in liquids, osmose, diffusion, vapour pressures of solutions, freezing points of solutions, salt solutions, and the simultaneous action of several solvents.

EXERCISES FOR TECHNICAL INSTRUCTION IN WOOD-WORKING: designed and drawn by H. Jay; arranged by E. R. Kidson. London: Longmans, Green, and Co.

These illustrations of the art of wood-working are shown on eighty-seven cuts divided into three sets, each set being contained in a cloth case. The different processes in carpentry and joinery are clearly shown, and short explanations are also given on the cards.

General Notes.

CHICAGO EXHIBITION.—The French Chamber of Deputies have just voted £130,000 as a grant for the proper representation of France at the Chicago Exhibition.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at Eight o'clock :—

APRIL 27.—Prof. ROBERT WALLACE, "Egyptian Agriculture." Lieut.-General MICHAEL, C.S.I., will preside.

MAY 4.—J. N. SHOOLBRED, B.A., "The Bradford Corporation Electricity Supply."

Papers, the dates of reading of which are not yet fixed :—

"The Fisheries Department: its Position and Prospects." By J. W. WILLIS BUND.

"Colour Blindness." By Captain W. de W. ABNEY, C.B., F.R.S.

"Uses and Applications of Aluminium." By G. L. ADDENBROOKE.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m. :—

APRIL 28.—Sir WILLIAM WEDDERBURN, Bart., "Reorganisation of Agricultural Credit in India." SAMUEL SMITH, M.P., will preside.

MAY 19.—JERVOISE ATHELSTANE BAINES, I.C.S., Chief Census Commissioner for India, "The Indian Census of 1891." Sir CHARLES BERNARD, K.C.S.I., will preside.

FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at Eight o'clock :—

APRIL 26.—Sir EDWARD BRADDON, K.C.M.G., "Australasia: its Progress and Resources." Sir ROBERT G. W. HERBERT, K.C.B., will preside.

MAY 24.—Colonel HOWARD VINCENT, C.B., M.P., "The Extension of Colonial Trade."

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock :—

MAY 17.—WILLIAM SIMPSON, R.I., "Mud as a Material for Architecture in India and the East."

Mr. Robinson is unable to read the paper already announced for this evening on account of ill-health, and Mr. Simpson has kindly agreed to take his place.

MAY 31.—WILLIAM DE MORGAN, "Lustre Ware."

CANTOR LECTURES.

Monday evenings, at Eight o'clock :—

DR. PERCY FRANKLAND, F.C.S., "Recent Contributions to the Chemistry and Bacteriology of the Fermentation Industries." Four Lectures.

May 2, 9, 16, 23.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 25 ....Chemical Industry (London Section), Burlington-house, W., 8 p.m.

Surveyors, 12, Great George-street, S.W., 8 p.m. Mr. E. G. Wheler, "Leases to Limited Liability Companies."

Actuaries, Staple-inn-hall, Holborn, 7 p.m.

Medical, 11, Chandos-street, W., 8½ p.m.

TUESDAY, APRIL 26...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Foreign and Colonial Section.) Sir Edward Braddon, "Australia: its Progress and Resources."

Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Mr. James Swinburne, "Electric Light Measuring Instruments." 9½ p.m. Reception by the President and Council.

Statistical, School of Mines, Jermyn-street, S.W., 7¾ p.m. Mr. R. Henry Rew, "An Inquiry into the Statistics of the Production and Consumption of Milk and Milk Products in Great Britain."

Photographic, Great Russell-street, W.C., 8 p.m.

Anthropological, 3, Hanover-square, W., 8½ p.m. 1. Professor R. K. Douglas, "The Social and Religious Ideas of the Chinese, as illustrated in the Ideographic Characters of the Language." 2. Mr. Joseph Offord, jun., "The Mythology and Psychology of the Ancient Egyptians."

WEDNESDAY, APRIL 27...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Prof. Robert Wallace, "Egyptian Agriculture."

Geological, Burlington-house, W., 8 p.m. 1. Mr. Ernest A. Floyer, "Notes on the Geology of the Northern Etbai, or Eastern Desert of Egypt; with an Account of the Emerald Mines." 2. Mr. Alex. Carson, "The Rise and Fall of Lake Tanganyika."

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Dr. E. Giltay, "On the use of the Camera Lucida in drawing Bacteria." 2. Mr. F. Chapman, "Foraminifera of the Gault of Folkestone." 3. Surgeon P. W. Basset-Smith, "On some Deep-Sea Deposits collected during a Voyage of Her Majesty's ship *Penguin*, 1891." 4. Mr. W. M. Osmond, "Simple Photomicrographic Apparatus."

Royal Society of Literature, 20, Hanover-square, W., 4½ p.m. (Annual Meeting.)

Royal Botanic, Inner Circle, Regent's-park, N.W., 2 p.m. Second Spring Exhibition of Flowers.

Civil and Mechanical Engineers, 7, Westminster-chambers, S.W., 7 p.m. Annual General Meeting.

THURSDAY, APRIL 28.. SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Sir William Wedderburn, "Reorganisation of Agricultural Credit in India."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Electrical Engineers, 25 Great George-street, S.W., 8 p.m. Mr. A. P. Trotter, "Notes on the Light of the Electric Arc."

The Telegraphic Address of the Society of Arts, and of the Royal Commission for the Chicago Exhibition, is "Praxiteles, London."

Journal of the Society of Arts.

No. 2,058. Vol. XL.

FRIDAY, APRIL 29, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Chicago Exhibition, 1893.

MEETING OF THE ROYAL COMMISSION.

A meeting of the Royal Commission was held on Wednesday, 27th inst. Present: Sir Frederick Bramwell, Bart., D.C.L., F.R.S., in the chair; Sir Frederick Abel, K.C.B., D.C.L., F.R.S., Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., Sir Owen Tudor Burne, K.C.S.I., C.I.E., Michael Carteighe, Francis Cobb, Sir Philip Cunliffe-Owen, K.C.B., K.C.M.G., C.I.E., Professor James Dewar, M.A., F.R.S., James Dredge, C. Malcolm Kennedy, C.B., W. H. Preece, F.R.S., Sir Owen Roberts, M.A., F.S.A., with Sir Henry Trueman Wood, M.A., as Secretary.

APPLICATION FOR SPACE IN THE BRITISH SECTION.

The Royal Commission are now able to announce that, her Majesty's Government having increased the grant placed at their disposal for the purposes of the British Section, from £25,000 to £60,000, they can dispense with any charges for space at the Exhibition, and will return to the intending exhibitors the amounts already paid on that account.

All applications must be made upon forms to be obtained from the Secretary of the Commission at their offices, Society of Arts, John-street, Adelphi, London, W.C. They must be sent in, properly filled up, and addressed to the Secretary, as above.

Proceedings of the Society.

EIGHTEENTH ORDINARY MEETING.

Wednesday, April 27, 1892; Lieut.-General J. MICHAEL, C.S.I., in the chair.

The following candidates were proposed for election as members of the Society:—

Collins, Ernest, The Gables, Wedderburn-road, Hampstead, N.W.
Deverell, Frederick Harold, The Custom-house, E.C.
Dowling, Dennis John, Bromley, Kent.
Elworthy, Herbert S., care of William Watson and Co., Bombay, India.
Fowler, Alexander Farquharson, Highfield, Ashton, Preston, Lancashire.
Gray, Robert, Glenclune, Port Glasgow.
Grinlinton, J. J., care of Darley and Butler, Billiter-square-buildings, E.C., and Colombo, Ceylon.
Grover, Colonel George Edward, R.E., British Section, World's Columbian Exposition, Chicago, U.S.A., and United Service Club, S.W.
Gwynne-Griffith, J. St. A. Mansel, Hendre-Owen, Bedford-park, Chiswick.
Hutchinson, Surg.-General Robert F., 35, Clanricarde-gardens, W.
Ismay, Thomas Henry, J.P., D.L., Dawpool, Birkenhead.
Jones, Julius Marris Wilson, 309, Kennington-road, S.E.
Kempster, William Henry, M.D., Oak-house, Battersea, S.W.
Osborne, Major-Gen. W., United Service Club, S.W.
Rollit, Sir Albert Kaye, M.P., LL.D., Dunster-house, Mark-lane, E.C., and Cottingham, East Yorks.
Sanbergue, Arthur de, 3, Victoria-street, S.W., and Barbadoes, West Indies.
Sandell, Henry William Adrian, M.R.C.S., L.R.C.P., Leighton Buzzard, Bedfordshire.
Sherwell, John William, Saddlers'-hall, 141, Cheapside, E.C.
Tonks, J. William, Victoria-street, Birmingham.

The following candidates were balloted for and duly elected members of the Society:—

Adams, Edgar T., The Cottage, Halstead, Essex.
Archer, Edgar, Ingleside, South Norwood-park, S.E.
Bean, Alexander Thomas, 7, Victoria-street, S.W.
Curtis, Alfred Harper, B.A., 13, South-hill Park-gardens, Hampstead, N.W.
Foster, William, M.A., Chemical Laboratory, Middlesex Hospital, Mortimer-street, W.
Gott, B. S., M.A., Corinium, St. Mark's, Cheltenham.
Hills-Johnes, Lieut.-General Sir James, K.C.B., V.C., Dolancothy, Llandilo, South Wales.
Pitt-Rivers, Lieut.-General A., Rushmore, Salisbury.
Staley, Thomas Peace, 2, Fenchurch-avenue, E.C.

The CHAIRMAN apologised for the absence of Professor Wallace, whose sudden indisposition entirely prevented him from travelling from Edinburgh.

The paper read was—

EGYPTIAN AGRICULTURE.

By Professor Robert Wallace.

Introduction.

By the land of Egypt is usually meant the broad fan-like expanse of the Nile delta and the narrow valley of alluvial land on the banks of the river as far south as Wady-Halfa, hemmed in on each side by rocky walls which have been left as the wearing action of the river in past ages formed the valley through the desert plains of North Eastern Africa. The whole country is completely dependent upon the supply of Nile water for its fertility. Eight inches is the mean annual rainfall at Alexandria, and in the neighbourhood of the Mediterranean coast during the winter season, and there is a rainfall throughout the delta, though in diminished quantities, in the direction of the south; still the climate is such that crops could not be grown without an artificial supply of water.

Basin Irrigation.

In the olden times, the method of applying water was extremely simple. Great earth walls near the banks kept the river within bounds at high flood, and the fertile areas were divided into large basins by earth-banks running across the country at convenient distances. Red water from the Nile was let into these basins, and allowed to stand to a depth of three feet or more, from about forty to sixty days, until the whole earth had become thoroughly saturated, until the weeds had been drowned or had died in the darkness produced by the muddy water, and until the fertilising layer of finely-divided red mud, brought down from the Abyssinian mountains, had been deposited to be left as an oozy warping. After the imprisoned water was allowed to escape into the falling or shrinking river, the seed was sown on the soft mud as the water receded. At times the land was left until it was dry enough to be ploughed, then it was thoroughly broken up and the seed sown on a well-cultivated but moist seed-bed. Sufficient moisture for the supply of the crop was retained under both circumstances, but where the soil was not ploughed after watering, the surface became very hard, and tended to crack and to injure the roots of the plants as they grew. This system of irrigation has almost disappeared from the delta or Lower Egypt, but it is still to be seen in Upper Egypt where, till this day, only one crop is gathered annually from a large proportion of the cultivated land.

Canal Irrigation.

Lower Egypt and a portion of Upper Egypt are under the canal system of irrigation, first introduced by Mohamed Ali, and now being rapidly developed and improved by the British engineers who were brought from the Indian Irrigation Department in 1882.

Modern Egyptian history may be said to date from the beginning of the time of Mohamed Ali, the founder of the present dynasty. All great improvements are in the native mind traced back to his time, and if the attempt be made to learn from tradition what existed in Egypt before him, the inquirer is met by the familiar native query, "Who knows?"

The difference in the power of the two systems to maintain soil-fertility may be gathered from the fact that a good crop of wheat grown under the basin system of Upper Egypt yields 5 ardebs (5·44 bushels each) or about 27 bushels per acre; while, unless specially manured, the yield runs down under canal irrigation to three and a half ardebs. In the latter instance the greater number of crops taken, and the reduced amount of Nile-mud deposited, make artificial manures necessary. A combination of the two systems gives by far the best results, as by judicious management the advantages of both can be secured.

Sabakh as Manure.

A wonderful store of natural manure, called "sabakh," has for a number of years been drawn upon by cultivators in the shape of refuse earth from the mounds of ancient villages and from the floors and surroundings of the mud huts of the present generation. The soil near human dwellings, of a primitive kind, naturally becomes incorporated with the solid and liquid excreta of the residents. In a climate like Egypt this is not nearly so much washed away by rain as would be the case in this country. It is therefore not to be wondered at that, after many generations have lived and died, large accumulations of valuable manure should exist, and that the cultivators should find out the value of it, and carry it long distances to their impoverished fields. Lines of camels and active little donkeys may regularly be seen streaming out of Cairo laden with the rich powdery earth riddled out of the immense rubbish piles of old Cairo.

The sabakh heaps must, within a few years, become exhausted, and artificial manures will

then be necessary to keep up soil fertility to its original very high standard under basin irrigation.

It is true that other means besides the direct application of manure can be resorted to in order to maintain the high degree of fertility. (*a*) Land under irrigation may be, from time to time, warped by muddy water as in basin irrigation; (*b*) the rotation of crops can be elaborated and improved by introducing "barsîm," or Egyptian clover, *Trifolium Alexandrinum*, which, like the bean and other leguminous plants, leaves the lands rich in fresh decaying vegetable remains containing organic nitrogen; and (*c*) greater numbers of live-stock, especially sheep, may be kept on the extended area of barsîm to increase the production of animal manure.

Surface Features of the Country.

The Nile delta is covered with an immense network of irrigation canals, mainly fed by three great arterial canals, which leave the river near the great Barrage, which stands a few miles to the north of Cairo, at the bifurcation of the Nile, where it divides into the only two remaining self-acting outlets which communicate directly with the sea, by name the Rosetta, or western branch, and the Damietta, or eastern branch.

The surface of the land, though unbroken by hills or rocks, and only here and there by palm groves or single standard trees, is by no means a uniformly level plain. It is ribbed by land lying along the banks of all the main waterways a few feet higher than the general level, owing to the tendency of sluggish flowing muddy streams to raise their banks for a considerable distance inland, and even their beds, above the level of the surrounding country.

The Damietta branch has this tendency more fully developed than the Rosetta branch. The latter scours its channel, whereas the former is sluggish, and liable to silt.

The banks, which are artificially raised along the sides of the rivers and canals generally to keep the high flood waters within control, have, in the case of the Damietta branch, to be exceptionally perfect; and even then they are a source of anxiety to the irrigation department, as the water at high Nile stands considerably above the level of the cultivated land outside its banks, and is liable to be flooded or drowned out in the event of the bank breaking—a misfortune which has repeatedly occurred in the past. It is found necessary to resort to the *corvée*, or forced labour, for the maintenance of the Nile banks. Happily, this degrading system is abolished in all but exceptional circumstances in which the interests of the community are involved. Watching the banks and repairing breaches in flood-time are necessary exceptions, but mending banks when there is no urgency is now—since, and including, 1890—done by contract, at Government expense. A broken river bank in Upper Egypt is not looked upon with alarm, as the land near the river in that division of country is above high Nile. The division banks of the basins are supported by the water they contain, and are not liable to suffer unless in windy weather, when waves are raised to wear away the tops of the banks if not properly bound with the roots of strong grasses or reeds.

River-training.

River-training is one of the practices in the irrigation department, introduced by the British engineers in Lower Egypt. It now costs £20,000 a year to make spurs to direct the river for the purpose of preventing erosion of its banks, and to save the land from being worn down and carried away. In Upper Egypt this work is confined to the saving of a mosque or some relic of antiquity.

In the olden times no effort was made to guide the course of the stream; if the natural bank of the river began to wear seriously, the protecting bank was shifted back to a sufficiently safe distance. It is a question whether this would not yet be best and cheapest in the end. The great advantage looked for during the course of ages would be the re-arrangement taking place under a natural process, of much soil along the immediate banks.

The recently introduced system of river-training has made it possible for a man who thinks that his property has been injured by the alteration of the river, to institute an action at law against the irrigation department. Formerly a cultivator held his land at his own risk, but he had also the right to go down stream, even for hundreds of miles, and take up newly-deposited land equivalent to that which he lost.

Excess of Salt in Soil.

Salt begins to show wherever the surface of the soil lies low, and is insufficiently drained, as in the neighbourhood of the salt lakes, which appear as an irregular chain within the crescent-shaped ridge of low sandhills skirting the Mediterranean coast. After thorough drainage has been established, the salt may

be removed within a few years by repeated washing or "leaching" with water, applied to banked-in areas of limited size, so that the water can sink through the body of the soil, and find its way into the surrounding drains. The salts, often present to the extent of 10 per cent. in the surface layer, have been brought up by water raised by capillary action through the soil, and then allowed to escape into the air by evaporation. The water is another source from which the accumulation is in part fed, as the clear Nile water contains 17 of salt in 100,000 of water, but no injury need be anticipated from this amount if good drainage is provided.

The water of the Nile also holds in its volume, possibly in solution, an unusually large per-centage of air, of which oxygen forms a most important ingredient. It is, probably, more or less due to this circumstance that Nile water is so healthful and palatable, even at its reddest, and in spite of the fact that the river is not only the main water-supply channel, but also the great common sewer of the country into which all sorts of filth, including dead animals, are thrown. The average native prefers water in the muddy state, rather than after it has been filtered.

Cost of Pumping Water and Land Tax.

When a regular rotation is maintained under an extensive system of cultivation, the annual cost per acre for pumping and distributing water at the season when water cannot be had "free flow," is estimated at from £1 to £1 10s. per acre. This latter, added to a tax of 160 piastres, raises the first charge upon the land above £3 per acre. When free flow-water is delayed, for even twenty days, it not only adds to the expense of the cultivator for pumping, but the yield of crop is very seriously reduced, possibly, in the case of maize, as much as two ardebs per acre. Should the Nile not rise sufficiently to give a cultivator free flow in flood time, he is entitled to pay only half his usual land-tax for the area on which the water failed to come. The flood months are four in number, usually extending from the 8th of July till the 8th of November, although the time rate, and extent of the rising and the falling of the river, vary considerably one year with another, and often give rise to well-grounded anxieties.

Crop Seasons.

The crop seasons are divided into three very distinct and very different, yet highly productive periods, conferring upon Egypt a special advantage over most countries.

1. The autumn or "Nili" (1st August till the end of November), the period of flood in which maize, millet, sesame, and a few minor crops are grown.

2. The summer or "Sefi" (1st April to the end of July), the warm weather period, in which tropical and semi-tropical crops, such as rice, sugar, and cotton are produced.

3. The winter or "Shitâwi" (1st December till the end of March), or cold weather period, when the European crops, such as wheat, barley, and clover, grown in a temperate climate, come to maturity.

The two latter seasons correspond more or less in point of time to our own summer and winter, Egypt being like Great Britain, north of the Equator, but the mean temperature is considerably higher in Egypt than in this country.*

Introduction of New Crops and New Methods of Cultivation.

Cotton is one of the chief products grown for export, and consequently, directly or indirectly, is one of the great sources of surplus wealth, and also invaluable as the means by which the country is enabled to pay the interest upon a debt of nearly £100,000,000 sterling. It is a crop of comparatively recent introduction, since the development of canal irrigation. Together these important recent departures present the best possible illustrations of the absurdity of the ideas of those who hold that it is impossible for us to improve Egyptian methods of working, or to do good by reflecting the light of European science upon certain dark corners of Egyptian practice. It is not the case that the Egyptian is following in the footsteps of ancestors who have trodden the same path for thousands of years, as the most prevalent system of irrigation, and many of the most important crops have been completely changed by European influences since the beginning of the present century.

At one time flax was extensively cultivated because England wanted linen; since that fashion has changed, and cotton is preferred in our home market, flax has practically disappeared, and cotton has taken its place. The Egyptian will grow anything for which he can secure a ready market and a remunerative return. For example, who would have thought

* The mean annual temperature at Alexandria is 69° F., and at Cairo 70° F., London 50·4°, Edinburgh 47·1°.

a few years ago that Egypt would aid in supplying the London market, early in the season, with young potatoes!

FOOD.

The bread on which the working-classes chiefly live, eaten generally along with raw green vegetables of different varieties, is so hard that it is necessary to soak it in water before attempting to use it. In Lower Egypt the chief ingredient is maize, while millet, *Sorghum vulgare*, supersedes it to a large extent in Upper Egypt; the thinnings of these crops while the plants are young and green are invaluable for tiding the work cattle over a period of scarcity. Wheaten bread is reserved for the upper classes, and for men employed on large contract works, where wages are usually higher than the average of the wages paid to cultivators, but barley-meal finds a place in the food of the working fellahîn.

THE FELLAHÎN.

In spite of what appears to us a meagre bill of fare, the fellah is very often a man of splendid physique, superior in strength and in endurance to the Indian ryot, whom he strongly resembles in many of his ways of working, in his habits, in his stolid lack of nervousness, and absence of fear of sudden danger to his person.

It is generally believed that the fellahîn of the present time are almost exact reproductions of their predecessors for countless generations, and that although the country has been frequently conquered, the new-comers were in matters of numbers insignificant in proportion to the great mass of the people, and consequently became rapidly absorbed. It is also a common belief that the soil and climate, and possibly the Nile water, exercise an influence in producing a certain type; for example, the prevailing nut-brown skin of the native of Lower Egypt. That this is so is almost a certainty, but the direction in which the influence works is frequently misunderstood. The result is more probably brought about by natural selection—the survival of the fittest—than by the infinitely slower process, under any circumstances, of the modification in a given direction of the individual units of succeeding generations. Two simple illustrations will serve to support this statement. Although many negroes, male and female, with jet black skins and protruding lips, come down to Lower Egypt from the Soudan and the Equatorial provinces, and inter-marry with the paler skinned Egyptians, the introduction of black skins gains no permanent ground. The climate of the delta, especially towards the north, where there is most rain, is too cold for negroes, and their descendants, pure and half-cast, usually die of pulmonary disease within a few generations. Again, Europeans and strangers to the country generally suffer and die from typhoid fever in vastly greater proportions than natives, many of whom possess immunity from the deadly consequences of this loathsome disease, although living under most insanitary conditions. Natives living in country districts, and being more exposed to the sun than those dwelling in towns, are darker in shade of skin; but this is simply the artificial darkening brought about by the sun, and corresponds to the influence exerted by it on people with dark complexions in this country.

COLOUR OF THE SKINS OF CATTLE.

It was interesting to note that the vast majority of Egyptian cattle had brown skins, irrespective of the colour of hair, differing not much in shade from the skins of the people, a colour which is represented to a greater or less degree among Indian cattle. Black skins in cattle are not so prevalent in Egypt as in India, but a pure pinky-white skin so frequently seen in England, and found only on rare occasions in India, was not met with in Egypt.

FEMALE LABOUR.

The Egyptian women of the labouring classes work very hard. They draw the household water supply from the river or from a neighbouring canal, carrying it in large earthenware jars, of native manufacture, upon their heads. In addition to household duties, they also work in the fields among the crops, and one may frequently be observed leading out to water and such scanty pasture as may be found, the family gamoos or black-skinned buffalo, *Bos bubulus*, a typical representative of the native milch cow of Egypt.

CATTLE.

The horned cattle of the country, other than the buffalo, belong to the same species as European cattle, *Bos taurus*, but are of a variety peculiar to the country. They are powerful and well-formed for work, high and pointed on the top of the shoulders (which are not crowned with the fleshy hump seen in Indian cattle), and particularly well-developed crest on the upper neck where the yoke rests. The horns are short, blunt, irregularly set, and

frequently pointing downwards, the antipodes of the long, elegant, up-turned horns of the cattle represented in the tomb paintings of ancient Egypt. It would seem as if the ancient race of cattle had died out from some one or other of the deadly forms of cattle-plague which at intervals sweep over the country. The re-stocking of the country could not be accomplished by the importation of European cattle, as these contract a peculiar form of blood-disease, no doubt of microbe origin, and usually die within two years after being imported.

It is rather a remarkable coincidence that the two last great outbreaks of cholera in 1865 and 1883, were immediately preceded on each occasion by a deadly cattle-plague, which filled the river with swollen and putrid carcasses and the air with unwholesome exhalations, especially in the vicinity of such places as the Damietta whirlpool, which is formed by the current at the abrupt bend of the river, where carcasses remained floating for days together. Horses, buffalos, and red-cattle died in vast numbers in 1864, while horses escaped at the last great outbreak, indicating that the cause of death was most probably not the same on both occasions. Of such matters there is, however, little chance of finding reliable written accounts, and the question must be practically left to conjecture.

While the donkey and the camel are the great beasts of burden in Egypt, red cattle are the faithful slaves and companions of the fellahîn who work in the fields. Cattle till the ground, working in native ploughs strongly resembling in general appearance the Indian plough, and doing work very much like that of a grubber or cultivator.

Egyptian Method of Threshing Grain Crops.

Cattle are also employed to tread out the seed, and while doing so, to break down and prepare for fodder the straw of the grain crops which is, when grown in a hot country, hard, dry, and unpalatable in its natural condition. When ready for use, it is called "tibbin" in Egypt and "bhusa" in India, where a similar method of threshing is practised. So much improved is the straw prepared in this way, not only in texture, but in aroma and presumably in flavour, and so accustomed are the straw-consuming animals to it, that they will not eat straw in the unprepared state with avidity, or thrive upon it if they do eat it. The hoofs of the cattle are aided in the work of threshing by a sledge-like implement called the "norag," drawn by a pair of bullocks, and driven by a man who sits comfortably on a wooden seat erected upon it. Though when at work it looks exactly like a clumsy wooden sledge, it really moves on two sets of thin iron discs, strung on two axles "drawn at a radius" of 50 feet, to give the implement an inclination to turn easily inwards.

The native implement is of rude workmanship, and is made to do more effective work by weights placed on the top of the frame. An improved "norag," by Murdoch & Co., of Mansourah, has the additional weights placed on the axles to reduce friction, and thereby lighten the draught.

Handling the Grain.

The cost of threshing and winnowing by the native method is about 8 piastres the ardeb (5·44 bushels), or equivalent to about 4d. per bushel, besides absorbing inconveniently the working power of a farm. On the Government Estate Domain at Coorishea, extending to some 20,000 acres, 400 pairs of cattle are employed for sixty-five days in threshing the crops. Steam-threshing machines have been recently so improved that the work of separating the grain and making excellent "tibbin," can be accomplished at the rate of 3d. per bushel of grain, a saving of 25 per cent. on the cost of the native method.

But for the high price of coal—30s. per ton at Alexandria—the cost of steam threshing would be less. Apart from the saving of expense, enormous advantage is derived from the use of steam-power in the cleanness of the sample. Grain taken from the earthen threshing floor is filthy with lumps of Nile-mud, the droppings of cattle, and other impurities, which all tend to increase the expense of transit and lower the price of that shipped to Europe. A door is also opened for dishonest practices, as the donkey or camel drivers steal what they can for their own use or even to sell, and make up the weight by adding earth to the remaining bulk. Some low class dealers are also said to be guilty of adulterating grain in this way, thereby injuring the reputation of Egyptian products in the foreign markets.

Egypt stands much in need of grain elevators, such as are largely used in America, for storing grain and also for cleaning and grading it according to quality. Though the money for their construction might be raised by a company, the interests of the country demand that the management should be directly under Government inspection.

The improvement of the market condition of grain is one of the improvements which the recently established Tewfikieh College of Agriculture has been instrumental in demonstrating.

The Tewfikieh College of Agriculture.

The college was named in honour of the late Khedive (Tewfik Pasha), who took a special interest in its success. This institution had its origin in a desire which sprang up little more than two years ago in the Egyptian Government to develop the agricultural resources of the country by calling in the aid of science. The result has been a success far beyond the most sanguine anticipations. During the first year of its existence the college contained about 60 students, selected from about 300 applicants, and the numbers of the second, the current year which began last October, have not fallen off. A number of the sons of large land-owners have taken advantage of the instruction offered, and it is hoped by this means to spread in all directions a knowledge of improved varieties of crop plants, improved rotations, improved implements, and improved methods, not necessarily altogether new to the country, but deserving of being more widely known. One of the main reasons why the college met with the approval and sympathy of the late Khedive was, that of all the educational institutions of the country, it is the one which holds out a prospect to its students of being able to do something on their own account, or in private employment, and not to trust, as too many educated Easterns do in Egypt, as in India, to securing Government appointments, or, as an alternative, give way to despair and discontent, if, indeed, not to disloyalty. The college has been organised by Mr. Williamson Wallace, the present director, who is associated with an admirably qualified and practical staff of scientific experts in the various subjects allied to agriculture; and even at this early period of its existence, it would be difficult to find in any part of the world a more completely equipped institution of the kind.

In addition to commodious residence-quarters, laboratories, and class-rooms located in a wing of the magnificent old palace of Ghizeh, there is a farm of 300 acres, which serves to demonstrate, practically, the work of the lecture-rooms. The rental value per acre is £5 per annum, although the soil is rather heavy, and not of the very best description. Its value is enhanced by its being located about two and a half miles from Cairo, which proves to be a ready market, so that wonderful prices can be obtained for certain crops; for example, £25 10s. per acre for a patch of early second years' sugar-cane for eating purposes, and £5 per acre for the cobs of green corn (maize), which is only a catch crop, occupying the ground for a short period.

In addition to the regular routine work, in which irrigation and cultivation, involving the use of the common implements, play important parts, elaborate experiments are carried out to test the effects of the available descriptions of manure, and the qualities of varieties of crop plants, such as the extremely important cotton plant, so liable to suffer from adverse atmospheric conditions, from fungoid diseases and insect pests, and from a natural tendency to degenerate in quality. The college staff has an immense field for original research-work open to it, which has not been scientifically explored. The main object of the institution will be to show how improvements can be made upon existing practices and existing available means, not to introduce European ways and methods to any greater extent than is demanded by the natural alteration in practices brought about by the increasing attempt to grow products to be shipped to European markets. In addition to results of immediate value to the country, from a practical and useful point of view, we may look with confidence to other results, which will be of general interest to science, as the outcome of the private researches of such men as the staff of the Tewfikieh College is composed.

The Locusts.

The plagues which afflicted Egypt in ancient times have not yet wholly disappeared. In 1891, during the month of April, immense swarms of migratory locusts (*Acrydium migratorium*) arrived from the west—possibly from Tunis or Algeria—and threatened to ruin the growing crops. It proved to be the most serious attack during 40 years, chiefly because the locusts bred in the country—not a common practice with them—increased at an alarming rate. The Cyprus locust, which at times does so much injury in that island, differs from the species which recently visited Egypt, in being smaller and in not being migratory. In external form, the Algerian locust is remarkably like the Egyptian grasshopper; but the latter is of a dull green colour, while the locust

is of a bright yellow. The bright colour is distinctly a disadvantage in the struggle for existence, as is seen when the numbers have been greatly reduced by artificial means, for then the native birds make quick work in despatching the remainder. The rate at which increase takes place is marvellous, the whole cycle of events from eggs to eggs being only 11 weeks. The female lays from 90 to 99 eggs, about one centimetre long, and she buries them about 5 centimetres (2½ inches) below the surface. The young locusts emerge after twenty days hatching, and at fifteen days old they club together, and march in search of food. From this time, in increasing degree till they are five weeks old, they are most voracious and destructive; they even attack and devour wounded specimens of their own species. At the latter period they throw off the first skin and develop full wings. They are most easily destroyed before they take flight, and the most simple method is to drive them into open ditches about 1 foot or 18 inches deep before they are fifteen days old, and to fill in the earth and thus bury them alive. When older, they may be driven into heaps of maize-cane to which they run for shelter, the heaps being afterwards burned. For a short time during the most critical period of the recent invasion, as many as 100,000 men, women and children, were called out by the Government to help in the work under the Corvée labour system. They were offered two piastres a day, and in some districts it is said that the fellahîn refused to accept the money as wages, although they are supposed to have taken a portion in the form of a present. The campaign lasted for six weeks, and nearly all were killed before they were old enough to develop wings. The great lesson which has been learned is, that it is possible, by energetic means within the power of Government, to prevent the wholesale damage to crops which is associated with the uninterrupted progress of locust swarms wherever they settle in the country.

Egypt for the Egyptians.

The cry of "Egypt for the Egyptians," is a sentimental one, and implies a condition of things which it is quite impossible to establish, although European influence were entirely removed. Very few of the true descendants of the old Egyptians occupy positions of influence, or are capable of taking part in the government of the country. The true Egyptians are, at present, unfit to govern themselves; the governing classes, apart from the western Europeans, being Easterns of foreign birth, or foreign extraction—Arabs, Turks, Armenians, Circassians, &c. The pashas, and men of large means, usually belong to one or other of these classes. If Egypt were left to the Egyptians proper, all representing these foreign nationalities ought to depart as well as the Germans, the French, and the English. But no such thing is within the range of practical politics, and the combination at present existing is in some respects an extremely suitable one.

The magnitude and unworkable nature of the machinery which is employed in the conduct of foreign affairs, embracing as it does the representatives of the great European powers, is detrimental to the progress of certain needed reforms which are supposed to involve the existing interests of other countries. The internal government of the country, however, carried on by the Easterns who have made Egypt their home within comparatively recent times, associated with the representatives of Her Imperial Britannic Majesty, at present in the persons of Sir Evelyn Baring and his official cortege, is a combination which it would be difficult to equal in theory, and impossible to approach in its efficient practice. It is of importance to know that the leading men who have the best interests of the country at heart appreciate the efforts being made by the British to strengthen the positions which have already been established, and to extend and consolidate the influences in favour of law and order. It is quite evident that, if British influence were removed, some other foreign influence which, to say the least of it, would not be an improvement upon that of the present time, would certainly strive to assert itself. It is only those who fancy they have something to gain in the scramble for place and power which would occur during the period of change who now grumble and complain, not in behalf of the country, but in the interests of themselves. The combination of Eastern and English influences in the government of Egypt is happy in its results owing to two main causes:—

(1) The English connection lends stability and security to the Government and raises the general tone, which is distinctly defective if judged from our high moral standpoint, in all purely Eastern forms of government; while (2) the Eastern element moulds within certain well defined lines the English ideas to make them serve to the best advantage the requirements of the people.

More than one important instance could be given to illustrate the advantage which has been derived from the association with the British legislators of natives in settling great agricultural, irrigation, and other problems, which involved vast interests, and called for much intimate personal experience in at least a number of the men entrusted with their solution.

French Influence.

Another burning question in Egypt is the position and power of France in the councils of the nation. Although France abdicated her share of the supreme power in military matters in favour of England, she still retains a right to many important lucrative appointments, and guards her interests in a most jealous manner; but her prestige as a nation capable of giving solid or useful advice and support to an Egyptian Government thrown upon its own resources (if such were possible), is gone. The position of France in Egypt is more that of a troublesome thorn in the flesh of England than as an aspirant to any substantial connection with the supreme government of the country. As a rule, Egyptian administrators, from the highest to the lowest of those now in power, have lost faith in the power of France to aid them in view of the practical examples of the way, in which the French conduct their home government and manage their colonies; and, moreover, the recollection of the fact that it was while acting under French advice that Ismaïl Pasha contracted the greater part of the burden of nearly £100,000,000 of debt, does not tend to develop any sympathies which may remain in favour of French influence.

Many of the French officials in Egypt are in themselves excellent men, but the French Government interferes so much with the private actions of her officials that they are made, with few exceptions, political agents, whose freedom of action is handicapped, and whose first interests are in consequence not so much as they ought to be with the country or the Government which pays their salaries, but with France, or rather with the limited section of the French people who maintain a sort of half-masked bitterness of feeling against England, because she chances now to occupy a position which, in a weak moment, the ruling authorities in France forfeited without compensation or reward.

Development of the People.

Egypt is developing in the science of governing as quickly as a country could do which had for at least 5,000 years been subjected to the most perfect form of personal, single-handed despotism; but it must be remembered that the growth of the governing instinct in a people is like the growth of intellect in a race; it cannot proceed by leaps and bounds, and can only prosper under conditions which induce slow and steady progress. Such conditions will remain as long as British influence is dominant in financial and military affairs. The qualities which have made Britain great as a colonising and a governing nation in every quarter of the globe are the untiring unselfishness and the unwavering uprightness and devotion to duty which is displayed by British officials in every grade of the public service. The influence is most seen when brought into contact with Eastern forms of government, where the standard of morality, in almost every sense of the term, is immeasurably inferior to our own.

The Late Khedive.

At the time of our visit—autumn, 1891—Egypt was to be congratulated upon her good fortune in possessing a ruler who took such a prominent personal interest in the prosperity of his country, as the late Khedive, Mohamed Tewfik, the sixth sovereign of the dynasty of Mohamed-Ali. His Highness was a man of great penetration and sound judgment in national affairs, and did not shrink from his share of the arduous duties which fell upon him, as the ruler of a people undergoing the process of liberation from the unfathomable depths of mediæval darkness, and the baneful consequences of slavery and tyranny.

Egypt is the only Eastern nation in which there is complete religious toleration, and where land is provided by Government for cemeteries and for the sites of mosques or churches for all descriptions of religious bodies.

The Khedive Tewfik had a high appreciation of the efforts Britain has made on behalf of Egypt. An agreeable personal interview with his Highness led us to believe that one of the most solid foundations upon which his opinion of the British rested, was a well-founded conviction of the fact that, in the conduct of their own affairs, they never lose command of their better judgment in momentary excitement.

It is a most natural conclusion to arrive at, that a nation which is able to conduct its own business creditably is a most suitable one to

lend another a helping and unselfish hand when required to do so.

The Present Khedive.

His Highness, the young Khedive, Abbas Pasha, promises to possess the good sense and sound judgment of his late and much lamented father, Tewfik Pasha, and at the same time an amount of individuality and determination which will, under the circumstances, prove a blessing to him and to his country. He displays praiseworthy anxiety to become fully acquainted with his Khedivial duties, discussing with his Ministers all subjects of importance, so that he may form his opinions correctly.

There are three special subjects in which he is particularly interested, viz., the army, education, and agriculture, and, if I may be allowed to say so, his choice is most judicious, and is an excellent indication of the existence of those superior mental qualities which he is accredited with, and which formed such a conspicuous feature in the character of Mohamed Ali, the founder of the present dynasty. The efficiency of the army is, perhaps his special hobby. He is by no means a tyro in the profession of arms. He underwent a thorough course of training in Austria, and he has also, seen during his travels, the monster armies of Europe. He is personally a judge of army matters, and there is during his reign every prospect of an efficient army being maintained not as an incitement to war, but as the best possible guarantee of peace, which for many years to come will mean increased prosperity and increase of wealth to all classes of the community. His Highness has already given proof of his interest in education by providing classes for secondary education in the Government schools of Alexandria, and we may rest assured that his good deeds in this direction are not at an end. He has given ample proof of his interest in agriculture by establishing a model farm at his Palace of Conha, where he spends much leisure time in admiring his animals, which have been selected from the best strains of the native breeds. He even attends to the details of the dimensions of his cattle-sheds. In a word, he is a Royal farmer when he can spare the time from being a soldier and a statesman. The Khedive, with all this, possesses great personal dignity and composure of manner which becomes him well. The sudden and lamented death of the late Khedive was truly sad, but Egypt is fortunate in having secured as his successor a young man of marked ability, naturally endowed with a conspicuous portion of Nature's most valuable gift—sound common sense.

The prosperity of Egypt is now an established fact, and it is only necessary to deepen the ruts to make the way to still greater progress permanent; but this will require patience and an amount of time which it is impossible to estimate at present.

DISCUSSION.

Dr. Voelcker said every one must regret the absence of Professor Wallace, and especially anyone who had had the opportunity, as he had, of hearing the lantern slides which had just been shown on the screen explained by the Professor; but, knowing his great energy and zeal, they might be quite sure that nothing but absolute necessity would have kept him away. Anyone who knew anything of Indian agriculture, must be struck with the relation which existed between it and that of Egypt, there being many striking points of resemblance, though also marked differences. Taking the similarities first, it would be observed that both countries were largely dependent on irrigation; Egypt had a great advantage in the silt, which was of immense fertilising value, but which only occurred in certain of the streams of India. In Egypt, also, salts were met with in the soil, but were more easily removed, owing to the more abundant supply of water. He believed Professor Wallace held that these salts could only be removed by prolonged washing with water, but, where this was not available, as in some parts of India, other means had been tried, and with some hopes of success. As regards the crops and the food of the people, there were also similarities: the wheat was hard, dirty, and adulterated in Egypt as in India. In the cattle, the hump which characterised the Indian breed was changed into a crest. While there were these similarities, there were also great differences, which had an important bearing on the improvement of agriculture in the two countries. Whereas India was divided up into very small properties, the separate holdings in Egypt covered a much larger area, and there the improvements were more easily carried out, and there was more scope for the use of machinery. At the same time there was a great deal to be said for the native implements and methods of cultivation. The cattle were very good, not so the sheep; and attempts to improve them by introducing English crosses had been more or less a failure in both countries. With regard to the people also there were decided differences, the Egyptian *fellah* having apparently the advantage over the Indian ryot. Professor Wallace had a theory of his own with regard to the skins of cattle, with which he did not altogether agree, and he thought that the general opinion in India was unfavourable to the doctrine that all the cattle had black skins. It now appeared that in Egypt the skins became shaded down to brown, but

personally he did not think there was much foundation for this theory. He was rather inclined to deprecate the introduction of political topics into a paper on agriculture. He must again express his regret that Professor Wallace had not been present to describe the slides, more particularly those showing the enormous irrigation works now being carried out, and which were as important as many of the Indian ones. The native methods of raising water were also very ingenious, and reminded him of what he had seen in India, and which it puzzled the best English engineer to improve upon. He remembered in particular one instance in which at one special depth, viz., 25 feet, a pump which had been brought from Australia did a little better, but at every other depth the native machinery was more effectual.

Mr. SHEPHERD said he was largely interested in this question in connection with a large tract of land, not far from Alexandria, which was referred to by Professor Wallace in his former paper, but the experience of the company was as yet but limited. They had come to the conclusion, however, that the land was especially favourable for the breeding and fattening of cattle and sheep. He thought Dr. Voelcker was slightly mistaken with regard to sheep. He remembered the Professor saying that, at the Agricultural College at Cairo, English sheep had been introduced, and had proved a failure; but they had come to the conclusion that crossing with the native breeds would be successful. Their attempts so far at breeding both sheep and cattle had borne out this idea, but it had not yet been carried out on a sufficiently large scale to judge of its commercial success. A particular kind of clover was found to be a very good crop for breeding purposes, and helped to create a valuable manure. The growth of cotton had not yet been carried out as it might be, but it had been tried to some extent, and last year 160 acres of land produced about £900. The tract of land to which he referred was surrounded by railways, was near the sea, and also the canal, so that it was very favourably situated for emigrants, especially Scotch farmers.

Mr. THEODORE WALKER said any one who had lately visited Egypt and North Africa must have noticed the great difference there was in the cattle of places not very distant from each other, such as Syria, Palestine, and Egypt. In Palestine, the cattle were very small, about the size of donkeys, and usually black. In Egypt, all the cattle represented on the tombs had long horns, but he was told they had all died out, and it struck him that the present breed was very much like the Indian; they seemed strong and robust, and in form were much like the cattle of Morocco, only the latter had long horns and a very large dewlap. Every visitor to Egypt must be struck with the exceeding fertility of the country; there seemed no stones; it was all a rich loam, and it was surprising that with such rich land the people should be so exceedingly poor and wretched. He was pleased to hear that the country was improving under the English occupation, and trusted it would be continued.

Mr. R. H. REW regretted exceedingly the absence of Professor Wallace, and should have been glad if instead of political allusions they could have had some further information as to the points in which Egyptian touched British agriculture. He was somewhat surprised to gather that the average production of wheat per acre was something like 27 bushels, which was highly creditable. He should have liked to ask the Professor if he could explain in any way the falling off in recent years of agricultural imports from Egypt. He had not the figures with him, but he believed it would be found that of late years there had been a great falling off in the import of wheat, and all kinds of grain and flour; whether that was merely an accident, or there was any particular cause for it he should like to know, and perhaps Dr. Voelcker could throw some light upon the question. He believed there was a slight increase in the case of wool.

Dr. VOELCKER said he should be inclined to attribute any diminution in the exports to a larger use of certain grains in the country itself. He knew that in India, if the export of wheat were not profitable, the people would either cease growing it, and produce some other grain, or they would use more wheat themselves. So long as Egypt had the fertilising influence of the Nile, and the silt which it brought down with it flowed over the country, there was not likely to be any deterioration of the soil or lessening of the crop. The silt was infinitely more valuable than any form of manure which an English farmer could place on his land. At the same time, not having been on the spot, he could not speak with any authority on the question asked.

Mr. J. HUGHES said he had not heard any special reference made to the quality of the Nile water, or the mud, to which so much value was attached. Some twenty-five years ago, or more, he was associated with the late Dr. Voelcker in analysing samples of this Nile water sent over specially by the Khedive, and the details would be found in the *Journal of the Royal Agricultural Society* about the year 1865. There were two special points about it —one, that the water was very soft; and the other, that it contained a considerable quantity of nitric acid, the fertilising value of which was very great. The mud was equal, if not superior, to any manure, for the simple reason that it was a complete manure, containing the various elements of plant food, and in a particularly fine form, which was a great advantage. A short time ago, he had occasion to analyse some warped soil from the eastern counties, and was struck by the fact that not only was it in a remarkably fine state of division, but was

very rich in lime, potash, and so forth. He should have liked to know if Professor Wallace had made any experiments confirmatory of the results obtained twenty-five years ago.

Mr. SCOTT said the native methods of raising water were very interesting, but he doubted if they were as efficient as more modern appliances. Some centrifugal pumps had lately been introduced, and worked very well. They were generally fitted with straw-burning apparatus, so that the high price of coal did not interfere with their use.

The CHAIRMAN said they must all regret that Professor Wallace was not present to reply to some of the questions which had been raised, but perhaps he would be able to do so in the *Journal*. The conditions of agriculture in Egypt were so different from those in any other country, except perhaps India, that it was very difficult to make them clear to those who had not been in that country; but Mr. Wallace had performed his task with great ability, and had given them a most interesting paper. Two interesting letters had appeared in the *Daily Graphic* for the 13th and 19th instant, written by his old friend and fellow-sportsman, Sir Samuel Baker, in which he described Egyptian agriculture; and he would commend those letters to the attention of all who were interested in the subject. Most people had but a faint idea of the vastness of the irrigation works of the ancient Egyptians. Herodotus, for instance, mentioned the great artificial lake Mœris, 400 English miles in circumference, which was made to store water for lands which were not inundated by the Nile, and they might fairly suppose that vast tracts of land which were now arid desert, were in those days cultivated, and perhaps afforested. Now that the Khedive's Government had taken in hand such irrigation works as were shown in the photographs, and had employed distinguished engineer officers, who were thoroughly acquainted with the irrigation works of India, to carry out similar works, it might fairly be hoped that, before many years were over, much of the land now uncultivated might be brought under cultivation Irrigation was the first thing wanted, and the next manure; but this was supplied, at the same time, by the water of the Nile; and when cultivation and tree-planting increased, an improvement in the rainfall might naturally be expected to follow. He believed that, since the opening of the Suez Canal, and the development of trees and gardens at Cairo and elsewhere, the rainfail had sensibly increased. The amount was now said to be about eight inches per annum at Alexandria, and it would be very interesting to know whether there were any statistics showing what it was 20 or 30 years ago. No doubt moisture attracted moisture, and it was well-known that the disafforesting of countries such as Palestine and Central India had turned them into desert wastes. There was every reason to suppose that by means of irrigation works now being started, the cultivation of trees would be promoted, which would tend to increase the rainfall, and thus to further increase cultivation. He concluded by proposing a vote of thanks to Professor Wallace, which was carried unanimously.

Miscellaneous.

CONGRESS ON INLAND NAVIGATION.

The fifth International Congress on Inland Navigation will be held in Paris in July of the present year. The work of the Congress will be divided into four sections—(1) Construction and maintenance of inland waterways; (2) technical working; (3) commercial working and economical questions; (4) waterways in their tidal part. In the programme of the Congress the various points for discussion will be as follows:—(1) Consolidation of canal banks; (2) water supply of canals; (3) leakage in canals; (4) reservoirs; (5) stoppages on canals and canalised rivers; (6) traction on canals, on canalised rivers, and on free rivers; (7) tolls and fees on waterways; (8) conditions of inland navigation ports; (9) respective uses of waterways and railways in regard to transportation; (10) improvement of tidal rivers, including their estuaries. Two principal excursions are being arranged for; the first will comprise the canals in the north of France, the *Fontinettes* lift and the Dunkirk and Calais docks; the second will consist of a visit to the canals in the centre of France, the works for canalising the Saône and straightening the Rhône and the *Furens* reservoir near St. Etienne. Smaller excursions on the Seine, Marne, and Paris canals will be organised during the Congress. The Congress, which is under the patronage of the President of the Republic, will be opened on Thursday, 21st July, in the Palais de l'Industrie (Champs Elysées), and will last for ten days. The president of the organising committee is Mons. Guillemain, Inspector-General of Ponts et Chaussées. The reports of the meetings will be printed in French, English, and German.

THE SALMON INDUSTRY OF THE RHINE.

The taking of salmon is an important industry of the Rhine provinces, and is regulated by an international agreement entered into, in 1885, by Germany, Holland, and Switzerland. The treaty is binding for ten years, and further, from year to year, until twelve months' notice of its expiration be given by one of the contracting parties. The jurisdiction includes the waters of the Rhine and its tributaries from Schaffhausen Fall in Switzerland, downward to the sea. The United States Commercial Agent at Magdeburg says that some of the leading provisions may be summed up as follows. No dams, nets, or

other obstructions for catching the fish may be erected for more than half the width of the river at low water, measured in the shortest line from shore to shore; further, the nets must not be over 2·5 metres in breadth, and must be stationed from each other at a distance of at least equal to double the length of the largest net employed. The fishing season is closed in Holland from the 16th of August to the 15th of October, inclusive; from the Dutch-German boundary upwards from the 27th of August to the 26th of October inclusive. During this period each Government pledges itself to prevent salmon fishing under the pretext of catching other fish. Further, in the Rhine tributaries, where the breeding districts are found, and in the Upper Rhine itself, above Mannheim, salmon fishing is only allowed during a period of at least six weeks, some time between the 15th of October and the 31st of December, by special permission of the authorities, and this special grant is only given on condition that the row and milt of the salmon shall be assured to the various artificial breeding ponds and establishments. Measures are taken to protect and promote salmon propagation as much as possible. It is stipulated that all the natural breeding spots in the tributaries shall be kept free and open to the fish ascending the river. It is left to each individual Government to settle for itself the lesser details, such as minimum length, tax, fines, &c., and it is especially agreed that nothing in the compact shall be construed to prevent any Government, in its own judgment, imposing severer regulations. Finally, a supervising commission is appointed by each nation, empowered to convene in international conference from time to time. Although the catch of salmon in Germany is annually very considerable, and salmon, like trout, is one of the delicacies of the table, the canning and preservation of this fish has not assumed any great proportions. It is carried on to some extent, but it has none of the importance of the industry of the Pacific coast.

THE GROWTH AND PRESERVATION OF POTATOES IN NANTES.

In a Consular Report from Nantes, recently issued by the Foreign-office, and dated February 25th last, Mr. Pauncefote gives some notes on the growth and preservation of potatoes during the winter. He says that last year's potato crop was a small one, in consequence of the unusual dryness of the summer, and, for this reason, there was but little disease. Wherever there was any disease, the treatment by sulphate of copper proved perfectly efficacious; and this applied equally to all parts of France where Consul Pauncefote had visited, and in some parts the disease had been very bad. In no one case had it failed; and, in some instances, patches that had been dressed, after the disease had attacked a field, recovered, while the rest went bad.

The dressing used is 3 lbs. sulphate of copper to 20 gallons of water; but experts say that a still better one is composed of 2 lbs. sulphate of copper and 4 lbs. of lime to 25 gallons of water.

The best results are obtained by using whole potatoes, sound, of medium size, being careful to select those which show the finest germs (but, if very large ones are used, they are cut in two), and planting widely. What is said to be the best and most disease-resisting kind yet discovered is at present very costly, the price being from £8 to £10 per ton, while the ordinary kinds cost from 32s. to 34s. per ton: but these last are said in the district to be of excellent quality. Some remarkable results have just been obtained by a gentleman farmer, who is also a distinguished chemical engineer, and has been, for some time past, engaged on experiments in potato growing. He has succeeded in getting the enormous return of 42 tons per acre—without using any of the improved or expensive varieties—from the magnum bonum and other ordinary kinds grown in the country. The following is the process he adopted:—The point of chief importance seems to be in the selection of the seed, and the use only of the very best and soundest tubers, which should be of medium size, and planted whole. The ground must be dug or ploughed very deeply, so that the tubers may have plenty of room to develop themselves naturally and easily, and should be well manured with either farmyard or chemical manure.

Before planting the seed potatoes, they are steeped for twenty-four hours in a bath composed of sulphate of ammonia and nitrate of potash, of each 6 lbs. to 25 gallons of water. After taking them out of this solution, they should be allowed to stand for twenty-four hours before planting, so that the germs may have time to swell, and it is to the increased activity of germination produced by this bath that the enormous return is attributed.

Grain, especially wheat, treated in a similar way, is said to have produced highly satisfactory results; for corn, however, there should be added to the bath 2½ lbs. of sulphate of copper.

In the matter of preserving potatoes during the winter, the best plan is said to be as follows:—After picking out the diseased ones, they are placed in a dry building or cellar in a heap of a yard deep; they are given as much ventilation as possible, but the doors should be kept closed when the weather becomes cold, and during the winter they should be visited from time to time, and stirred with a shovel.

For badly diseased tubers the following mode of treatment is said never to fail in arresting the disease. Take them, as soon as possible after they are dug up, and dry them. Make a bath with water and as much lime as it will take up, put the potatoes into baskets and dip them for a few minutes in the solution, and dry them in the shade, stowing them away in the manner described above. The diseased part seems to solidify after this treatment, and does not

spread, while the good part continues perfectly sound, and can be used, without any bad results, for feeding animals, or even for table.

Notes on Books.

"THE GRASSHOPPER" IN LOMBARD-STREET. By John Biddulph Martin. London. 1892. 4to.

In this handsome volume Mr. Martin points out that Lombard-street has its legendary history : thus, number 68 is associated with Matthew Shore, the supposed husband of the ill-fated Jane Shore, and legend has even grown up around Sir Thomas Gresham and his family crest of the grasshopper. An absurd tradition has been often repeated, that Gresham was a castaway infant, exposed in a field, and discovered by a casual passer by, whose attention was attracted by the loud chirping of a grasshopper ; hence, when he acquired wealth and dignity, he assumed the grasshopper as his crest; the fact being, that the Greshams were a well-known Norfolk family long before the famous merchant's birth. Mr. Martin refers to Sir Richard Martin, who was called to the Livery of the Goldsmiths' Company in 1558, and in 1605 was the oldest alderman in the city of London. He was Master of the Mint and Lord Mayor in 1589. His arms were the same as those of the bankers, but it is not known that he was in any way connected with the "Grasshopper."

The authentic history of the famous house, which afterwards became the banking firm of Martins, commences in the second half of the 17th century. In 1677, 17 years before the foundation, in 1694, of the Bank of England, the house is mentioned in the "Little London Directory." At the end of this book is inserted a supplementary list of the "goldsmiths that keep running cashes;" and among them are mentioned "Chas. Duncomb and Richard Kent, at the 'Grasshopper' in Lombard-street." The Duncombe family was connected with the Greshams by marriage; and Charles Duncombe was apprenticed to the famous Alderman Edward Backwell, who is so often mentioned in "Pepys's Diary." The partnership between Duncombe and Kent was dissolved in 1688, by the death or retirement of Kent. Shortly afterwards, Richard Smith (b. 1659 d. 1699)—whose portrait by Huysman still hangs in the bank—took a prominent part in the management of the business. He engaged, as a clerk, Thomas Martin, who, after Smith's death, became partner with Andrew Stone. Their names are associated together in 1703, and from that time forward the business was mainly conducted by members of the two families, until 1852, when Mr. George Stone left the firm. At his death, on the 15th July, 1861, the Stone family became extinct in the male line, he being the great, great-grandson of Andrew Stone.

After clearing up the various difficulties connected with the history of the different partners, from Duncombe to the Martins and Normans, who now constitute the firm, Mr. Martin gives an account of the growth of modern banking, and full particulars of the alterations made at different periods in the occupation of Change-alley. These particulars are made clear by the insertion of several maps and plans.

REPORTS ON THE CULTIVATION OF THE SPANISH CHESTNUT. India-office. 1892. Folio.

This Indian "green-book" contains Reports on the use of Chestnuts for Food in Italy, by Sir Dominic Colnaghi, and P. Gavazzi and G. Maldifassi; on the "Cultivation and Production of Chestnuts in the Province of Asturias," by W. Pendleton; and on the "Chestnut Trees of Catalonia," by Don Ricardo Acebal. The historical introduction, by Sir George Birdwood, is full of learned information respecting the introduction of the chestnut and other trees into Europe. The chestnut is a native of Central and Middle Asia, and it appears to have been introduced into Italy between the time of M. Porcius Cato, B.C. 234-149, and of Virgil, B.C. 70-19, the latter being the first Latin writer to refer definitely to them.

The systematic cultivation of the chestnut tree, and its present wide-spread growth in the United Kingdom, is, as Sir George Birdwood states, "entirely due to the action of the Society of Arts at the end of the last and the beginning of the present century, in offering prizes to those landowners who showed themselves most zealous in forming plantations of the tree." It was hoped that by this means the building timbers of the country would be increased, but in this case the hope proved illusory. The popular idea that the roof of old buildings, such as Westminster-hall, were formed of chestnut has been shown to be erroneous. The wood really used was that of the chestnut oak (*Quercus robur*).

In 1864, Sir George Birdwood forwarded from Bombay, at the request of Prince Halim Pasha, sixty specimens of the finest forest trees of Western India for experimental cultivation in Egypt; and respecting the systematic naturalisation throughout Syria and Northern Africa of the hardy leathery-leaved dry season trees and shrubs of the coasts of Southern India he writes: "Strangely beautiful in the parched months of April and May are the frequent evergreen thickets in the island of Salsette, and elsewhere in the Concans, of mixed *bukuli* (*Ixora Bandhuca*) and *karunda* (the 'Corinda' of Anglo-Indian *Carissa Carandas*); the former with its terminal corymbs of of bright scarlet, and the latter with milk-white jasmine-like flowers and large plum-like berries, coloured in the degree of their maturity, from lustrous pea-green and purest ivory, through every tint of celestial rosy red to ruby crimson and glowing purple, and shining, in their gay varigation, against its dark, glossy foliage, as though it were an illuminated tree of fairyland, with all the fairy court

dancing in the charmed climate of its fragrant and refreshing shade. Wherever it blossomed and fruited in Northern Africa it would make a Paradise."

Referring to the spread of vegetation over the globe, Sir George Birdwood writes:—"Yet with all the enlarged knowledge placed at our disposal by modern botanical science, and with all the equipments of an empire, out-stretched over every quarter of the globe at our command, how little shall we ever be able to accomplish in promoting an interchange of economic plants between the East and West, and adding in this way to the happiness of mankind compared with the unstudied, casual, and almost unconscious transformation effected in the vegetation of the countries of the Mediterranean Sea, with such incalculable results in the increase of their material wealth and the impulse thus given, and still operative, to human civilisation by the propagation throughout them of the worship of the gods of Phœnicia and Greece." After referring specially to the vine, the date palm, the olive, the myrtle, and the rose, Sir George thus closes his introduction:— "It is impossible to stigmatise as superstitions beliefs and rites that conferred such enduring benefits on the world. But for them the civilization of Europe might possibly have never advanced beyond that of newer stone age, preceding the age of bronze ushered in with the westward advance of the commerce and religion of the Phœnicians, and it is evident, in view of the facts here adduced, that they were the divinely appointed means for working out, in the long-suffering patience of Providence, the eternal purposes of God toward man."

Obituary.

Sir JAMES ALLPORT.—Sir James Joseph Allport, who died at the Midland Hotel, St. Pancras, of acute inflammation of the lungs, on Monday evening, 26th inst., was a native of Birmingham, where he was born in 1811. In 1843, he became manager of the Birmingham and Derby Railway Company, from which position he moved, in the following year, to the Newcastle and Darlington Railway (subsequently the York, Newcastle, and Berwick Railway). After six years in the northern county, Mr. Allport accepted office on the Manchester, Sheffield, and Lincolnshire Railway, and remained in it for three years, when he became manager of the Midland Railway, a position which he filled for 27 years. It was during these years that this railway grew from a local line into a great trunk route, the extension to St. Pancras being completed in 1868. The most notable of the measures by which he endeavoured to render railway travelling cheap, comfortable, and expeditious were the running of third-class carriages on all trains, which was commenced in 1872, and the abolition of second-class carriages two years later. In his 70th year, Mr. Allport resigned the managership, and was elected a director of the Midland Company, and presented with £10,000. He was knighted in April, 1884. From 1865 to 1883, Mr. Allport was Lieutenant-Colonel in the Engineer and Railway Volunteer Staff Corps. He was also an Associate Member of the Institute of Civil Engineers, and a Justice of the Peace for the borough and county of Derby. Sir James Allport had been a Member of the Society of Arts since 1852, and on several occasions, when railway subjects were discussed at the Meetings of the Society, he joined in the discussions.

General Notes.

AUSTRIAN WINE PRODUCTION.—The Austrian Minisiter of Agriculture has recently published the figures of the wine production of Austria in 1891. In the official returns, no reference is made to Hungarian production. According to the statistics, the total quantity of wine produced amounted to 66,114,000 gallons, distributed as follows:—Lower Austria, 11,044,000 gallons; Styria, 6,490,000; Carniola, 2,112,000; Carinthia, 3,740; Tyrol and Vorarlberg, 4,048,000; Coast land, 13,904,000; Moravia, 3,212,000; and Dalmatia, 25,300,000 gallons. To have been absolutely complete, the returns should have included Bohemia, but the figures of the wine production of this kingdom are not of sufficient importance to materially affect the total. Comparing the total Austrian product of 1891 with that of 1890, it is found that the yield of last year was lower by 22 per cent. than that of the preceding one, a very serious falling off, more especially when it is considered that the deficit is getting larger every year, and the vintage of 1890 was by no means more than an average one.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at Eight o'clock:—

MAY 4.—J. N. SHOOLBRED, B.A., "The Bradford Corporation Electricity Supply." W. H. PREECE, F.R.S., will preside.

MAY 18.—Captain W. de W. ABNEY, C.B., F.R.S., "Colour Blindness."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

MAY 19.—JERVOISE ATHELSTANE BAINES, I.C.S., Chief Census Commissioner for India, "The Indian Census of 1891." Sir CHARLES BERNARD, K.C.S.I., will preside.

FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at Eight o'clock:—

MAY 24.—Colonel HOWARD VINCENT, C.B., M.P., "The Extension of Colonial Trade."

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock:—

MAY 17.—WILLIAM SIMPSON, R.I., "Mud as a Material for Architecture in India and the East." General ROBERT MACLAGAN will preside.

MAY 31.—WILLIAM DE MORGAN, "Lustre Ware."

CANTOR LECTURES.

Monday evenings, at Eight o'clock:—

Professor PERCY F. FRANKLAND, Ph.D., B.Sc., F.R.S., "Recent Bacteriological and Chemical Research in connection with the Fermentation Industries." Four Lectures.

LECTURE I.—MAY 2.—Introduction—Study of micro-organisms — Microscopic examination—Principles of staining, &c. -- Cultivation of micro-organisms.

LECTURE II.—MAY 9.—Culture media—Methods of sterilisation—Pure cultivation—Special methods for the cultivation of particular micro-organisms.

LECTURE III.—MAY 16.—Practical results of recent investigations—Hansen—Alcoholic fermentation with and without oxygen—Carbohydrates fermentable by yeasts —Artificial sugars in their relationship to yeasts—Fermentations of milk.

LECTURE IV.—MAY 23.—Bacterial fermentations —New products resulting therefrom—Micro-organisms in their relation to agriculture—Nitrification—Fixation of atmospheric nitrogen by plants.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 2 ... SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Dr. Percy F. Frankland, "Recent Bacteriological and Chemical Research in connection with the Fermentation Industries." (Lecture I)

Farmers' Club, Salisbury-square Hotel, Fleet-street, E.C., 4 p.m. Mr. Druce, "Small Holdings."

Engineers, Westminster Town-hall, S.W., 7½ p.m. Mr. Samuel Herbert Cox, "Dry Crushing Machinery."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Prof. Wm. Ramsay and Mr. J. C. Chorley, "The Distillation of Wood." 2. Dr. S. Rideal, "Notes on the Composition of some Indian Gums of known origin."

British Architects, 9, Conduit-street, W., 8 p.m. Annual Meeting.

Medical, 11, Chandos-street, W., 8½ p.m. Annual Oration.

Victoria Institute, 8, Adelphi-terrace, W.C., 8 p.m. Sir C. Wilson, "The Past and Present Water Supply of Palestine."

TUESDAY, MAY 3 ... Royal Institution, Albemarle-street, W., 3 p.m. (Tyndall Lectures.) Professor T. G. Bonney, "The Sculpturing of Britain: its later stages." (Lecture II)

Central Chamber of Agriculture (at the HOUSE OF THE SOCIETY OF ARTS), 11 a.m.

Civil Engineers, 25, Great George-street, S.W., 8 p.m. Discussion on Mr. Swinburne's paper "Electrical Measuring Instruments."

Pathological, 20, Hanover-square, W., 8½ p.m.

Biblical Archæology, 9, Conduit-street, W., 8 p.m.

Zoological, 3, Hanover-square, W., 8½ p.m.

WEDNESDAY, MAY 4 ... SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. James N. Shoolbred, "The Bradford Corporation Electricity Supply."

United Service Club, Whitehall-yard, S.W., 3 p.m. Lieut. F. T. Hamilton, R.N., "The Application of Electricity to Torpedo and other Naval Purposes."

Entomological, 11, Chandos-street, W., 7 p.m.

Archæological Association, 32, Sackville-street, W., 4½ p.m. Annual Meeting.

Obstetrical, 20, Hanover-square, W. 8 p.m.

THURSDAY, MAY 5 ... Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Linnean, Burlington-house, W., 8 p.m. 1. Dr. J. Mueller, "Lichenes Epiphylli Spruceani." 2. Mr. W. F. Kirby, "Notes on the family *Saturniidæ*, with descriptions of new Species in the Collection of the British Museum."

Chemical, Burlington-house, W., 8 p.m. Ballot for election of Fellows.

Society for the Encouragement of Fine Arts, 9, Conduit-street, 8 p.m. Dr. G. W. Leitner, "The Fairy Land of the Pamirs."

Royal Institution, Albemarle-street, W., 3 p.m. Professor Dewar, "The Chemistry of Gases." (Lecture II.)

Mechanical Engineers, 25, Great George-street, S.W., 7½ p.m. 1. Inaugural Address by the President. 2. Professor Alexander B. W. Kennedy, "Research Committee on Marine-Engine Trials: Report upon Trial of the steamer *Ville de Douvres*."

Archæological Institution, Oxford-mansion, Oxford-street, W., 4 p.m.

FRIDAY, MAY 6...United Service Institution, Whitehall-yard, S.W., 3 p.m. Colonel F. J. Graves, "Military Education."

Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting. 9 p.m. Captain Abney, "The Sensitiveness of the Eye to Light and Colour."

Junior Engineering Society, Westminster-palace-hotel, Victoria-street, S.W., 8 p.m. Mr. John Taylor, "Naval Construction at Poplar."

Geologists' Association, University College, W.C., 8 p.m.

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Physical, Science Schools, South Kensington, S.W., 5 p.m.

Mechanical Engineers, 25, Great George-street, S.W., 7½ p.m. Lieut.-Colonel Thomas English, "Condensation in Steam-Engine Cylinders during Admission."

SATURDAY, MAY 7...Royal Institution, Albemarle-street, W., 3 p.m. Mr. E. Dannreuther, "J. S. Bach's Chamber Music." (Lecture II.)

The Telegraphic Address of the Society of Arts, and of the Royal Commission for the Chicago Exhibition, is "Praxiteles, London."

Journal of the Society of Arts.

No. 2,059. Vol. XL.

FRIDAY, MAY 6, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

GENERAL MEETING.

TEMPORARY ALTERATION OF BYE-LAWS.

The Council hereby convene a General Meeting of the members to be held at the Society's House, in the Adelphi, on Wednesday, the 18th May, 1892, at 4 o'clock in the afternoon, for the purpose of considering, and if thought desirable of passing, the following resolutions :—

1. That in accordance with the proposal from the Council, the Bye-laws be altered and varied in such manner that the Council shall be empowered, during the years 1892 and 1893, to appoint not more than six members to be Vice-Presidents or other Members of the Council in addition to those appointed under Bye-laws 79 and 84, and that the Council be empowered to determine the period or respective periods that members so appointed shall continue in office, not being later than the end of the Session commencing 1893, and that all Bye-laws which are inconsistent with such appointment and determination be suspended or varied.
2. That Bye-laws 8, 9, and 10 be suspended during the Sessions 1892-3 and 1893-4.

By Order of the Council,

HENRY TRUEMAN WOOD,
Secretary.

2nd May, 1892.

Bye-Laws 8, 9, *and* 10.

8. The Chairman of the Council shall be chosen from those Members of the Council who are of one year's standing at least.

9. The Chairman of the Council, after two years' service, shall not be re-eligible to the office for at least one year.

10. The Chairman of the Council shall deliver an address to the Society at its Ordinary Meeting after his election.

CANTOR LECTURES.

Professor PERCY F. FRANKLAND, Ph.D., F.R.S., delivered the first lecture of his course on "Recent Bacteriological and Chemical Research in connection with the Fermentation Industries" on Monday evening, 2nd inst.

The lectures will be published in the *Journal* during the autumn recess.

UNION OF INSTITUTIONS.

The following institution has been received into union since the last announcement :—

Bootle Technical School.

Chicago Exhibition, 1893.

APPLICATIONS FOR SPACE.

Notice is given that applications can only be received up to Saturday, 21st May. Any applications received after that date will be filed, in case of any space becoming hereafter available, but will not be included in the allotment.

All applications must be made upon forms to be obtained from the Secretary of the Commission at their offices, Society of Arts, John-street, Adelphi, London, W.C. They must be sent in, properly filled up, and addressed to the Secretary, as above.

HANDBOOK OF REGULATIONS.

A "Handbook of Regulations and General Information" connected with the Royal Commission has been printed, and can be had on application to the Secretary of the Royal Commission, Society of Arts, John-street, Adelphi. The Handbook contains lists of the Commission, of the various Committees,

and of the Colonial Commissioners, Synopsis of the Classification, General Regulations, Regulations of the British Section, Traffic Arrangements and Customs Regulations, descriptions of the various Departments, Abstract of the McKinley Tariff Rates, Description of Chicago and the Exhibition, and account of the routes to the city.

Proceedings of the Society.

FOREIGN & COLONIAL SECTION.

Tuesday, April 26, 1892; Sir ROBERT G. W. HERBERT, K.C.B., in the chair.

The paper read was—

AUSTRALASIA: ITS PROGRESS AND RESOURCES.

BY SIR EDWARD BRADDON, K.C.M.G.

In the *Westminster Magazine* for January, 1780, is to be found "A Sketch of the Life and Services of the late Captain James Cook," which eulogises Cook as the compeer of Columbus, De Gama, Magellan, Hawkins, Drake, and Raleigh; which tells us of the vessels he commanded and other details of his expeditions; but which, strange to say, utters not a word about Cook's greatest exploit, viz., the practical discovery of Australia as territory suitable for English colonisation.

Indeed, the only approach to mention of the Australian continent to be found in this paper is in an extract from the oration made by Sir John Pringle, what time the Royal Society awarded Sir Godfrey Copley's gold medal to Cook: and this extract is to the effect that Cook had dispelled the illusion of a *terra Australis incognita;* and I may add that this medal was awarded not for Cook's discoveries, but "for the account which he had transmitted to the Society of the method taken to preserve the health of his crew."

It is, moreover, carefully impressed upon readers of this magazine, that Cook's expedition in 1772-4 "to complete the discovery of the southern hemisphere," was a failure. "It had long been a prevailing idea," says the author of this sketch, "that the unexplored part contained another continent," but, according to this narrative, Cook carefully sought for this continent in regions very remote from the locality where it was to be found; and the account of Cook's last voyage of 1776, which resulted in the great navigator's untimely death on one of the Owaihi Islands, says nothing that removes the impression that Cook failed from first to last to discover Australia.

In short, the *Westminster Magazine* of 1780 showed a degree of ignorance on this subject which must be regarded as astounding, even by comparison with the ignorance of things Australasian still discoverable in this country. From before the commencement of the Christian era, geographers had held by the belief that a continent must, for purposes of equilibrium, be in existence in the southern region, where or whereabouts Australia is. Before the time of Mercator, such a continent was charted tentatively. Old maps of 1531 and 1542 have marked upon them an extensive country south of the Moluccas named *Jave la Grande*, which agrees more narrowly with the position and extent of *Terra Australis* than with any other land; and, as the names of geographical features of this chart are Portuguese, it is claimed that they (the Portuguese) were the first discoverers. Dr. Lardner held that the Spaniards and Portuguese visited the north and east coasts nearly a century before that country was discovered by the Dutch. The French are said to have actually discovered this continent before 1531. And its discovery by the Portuguese explorer, Manoel de Eredia, in 1601, and subsequent confirmation of this, by the visits of other explorers between 1601 and 1770, when Cook landed at Botany Bay, are matters of history. Yet did the *Westminster Magazine*, in 1780, speaking of Cook's voyage of 1772-4, quote, without comment or contradiction, the opinion that it had "dispelled the illusion of a *terra Australis incognita*."

As a fact, Australia had been proved, prior to the date of that magazine, a very much discovered reality, even supposing that Manoel de Eredia was, in 1601, the first in the field. In 1606 it was rediscovered by the Dutch, and by Quiros, who named it *Australia del espiritu santo*, in honour of Philip of Austria. In 1618, Zeachen, a Dutchman, surveyed the north. In 1619, another Dutchman, Edels, surveyed the west coast. In 1622, the Dutch ship *Leewin* visited and bequeathed its name to West Australia. In 1627, the Dutch Nuyts and the English Carpenter surveyed the south and north coasts respectively. In 1628, De Witt came, and left De Witt's land in evidence of his visit. Tasman discovered Tasmania in 1642, under the impression—which survived in Australia until the discovery

of Bass' Strait, in 1797, and which still exists very largely here—that this was a part of the continent. In 1665, Terra Australia was renamed New Holland, by order of the States General, as evidencing that shadowy claim of the Dutch, which never came to be other than phantasmal. From 1684 to 1690, William Dampier explored the western and north-western coasts; in 1705, Captain Martin Von Delft, with three vessels, explored and named the north-western coasts; Willis and Carteret explored the continent in 1763-6; and, finally, Captain Cook landed at Botany Bay, on the 28th April, 1770, and took possession of Australia, or, as he styled it, New South Wales, in the name of King George.

Captain Cook's methods of discovery differed in two important particulars from those of his predecessors. (1) He took formal possession of the country, which no one else seems to have done, perhaps because no other had sufficient observation and foresight to see that it was worth possessing; and (2) he wrote for his Government a report which strongly recommended this newly-found territory for British colonisation.

On the 26th January, 1788, Governor Phillip founded Sydney, and the career of Australasia commenced. Born 104 years ago, Australasia is still in its infancy. What is the adolescence into which such a sturdy stripling may be expected to develop?

It is said that England hastened to colonise Australia in view to finding in that possession compensation for the colonies lost to her (and, be it added, *by* her) in America. But this does not appear a very plausible proposition—it certainly is not a convincing one. Cook took possession of Botany Bay in 1770; the American colonies were declared free in 1776. Only in 1788 was the first colony fonnded in Australia.

There is a striking contrast between the colonial empire that remained to England when the United States were lost to her in 1776, and that which now owns allegiance to this mother of nations. We had, during the 17th century, been eclipsed in this line of conquest by the Dutch, who had acquired Batavia, in Java, in 1610, Manhattan, now New York, in 1624, Cape Town in 1650, and Trincomalee and Chinsurah in India, through the Dutch United East India Company, chartered in 1602. During that century the Dutch vied with England for mastery of the sea; the names of Van Tromp and other bold captains of the States General were associated for Englishmen with defeat that Englishmen were not accustomed to; our forefathers were insulted by a broom hoisted on a Dutch vessel as an insolent signal, and the courtiers of Charles II., at Whitehall, heard, as Macaulay tells us, the roar of guns of an invading Dutch fleet. They had been, moreover, more active than any other power in exploiting Australasia.

When England lost the United States of America, she had little left to her but (1) India, with such very limited rights of sovereignty as the British East India Company had acquired by Imperial grant over Bengal, Behar, and Orissa, her recently conquered provinces of the Carnatic: and the town of Bombay, which came to Charles II. as the dower of his queen; (2) the West Indies, and (3) Canada, conquered in 1759, when Wolfe died on the heights of Quebec in the hour of victory, this conquest being confirmed by the Treaty of Paris, 1763.

When New South Wales was founded, there was in existence only one of the three great colonial groups that now mainly constitute what we know as Greater Britain, viz., Canada, which, at that time, was little more than the Province of Quebec; Australasia was being created, and the Cape of Good Hope was in the possession of the Dutch, until finally ceded to the English in 1814, having been first taken in 1795, restored at the peace of Amiens, in 1802, and retaken in 1806. In the three colonial congeries of States, where there are now over 10,000,000 of British English-speaking subjects, there were, in 1788, barely 10,000.

New South Wales, the mother colony of Australia, founded in 1788, with a penal settlement attached to it, and other signs and portents of Imperial dominion, started in a sufficiently modest way and encountered a full share of the trials and tribulations natural to early settlement in an unknown and savage country. It was not a wholly unpeopled land before the advent of the English, but the Australian aborigines had done nothing to make the way of the new-comers smooth for them, while they did a good deal on occasion to roughen it. The natives had no idea of cultivating the soil; indeed, they may be said to have had a natural repugnance to husbandry or incapacity for it which time has in no degree modified. Of a very much lower type than the South Sea Islanders, they lived very much the lives of beasts of prey, subsisting upon fungi, grubs, shell fish, and such animals as they could hunt down in the bush, with an

occasional dietary change when a man and brother made the meal. They were a people who had not yet emerged out of the flint age, and were little amenable to the influences of civilisation when civilisation other than rum came within their reach. They have, it is true, made concessions in regard to cannibalism: they do not eat each other; but, although they make fairly good stock-riders and shepherds, and have proved useful as trackers in the police, they are no more given to agriculture now than when Governor Phillip first reigned in Sydney.

I may dispose of the Australian aborigines here, and finally. They have in the past given trouble; even now there are occasions when those of Northern Australia treacherously slay the white settlers, or raid the white man's flocks and herds. But they have, as a rule, little or no influence on the life and destiny of the nation, and they are decreasing in numbers in spite of philanthropic efforts of the Government to preserve them. The Australian aborigines were, I imagine, never a numerous race. It was not to be expected of people who regarded each other as a possible meal to become so. The total number conjectured to have peopled the continent when the English first took possession of the country was 150,000; there are now about 58,000, whereof some are protected in Government asylums or refuges. In New Zealand there are of that vastly superior race, the Maoris, 41,523. In Tasmania, where the lowest type of all was found, there is no survivor.

Settled in a land which, until they came, had never yet been tickled by the plough, or laughed with a harvest, the New South Wales pioneers very early in their career experienced the direst privation; and from 1806 to 1810 gaunt famine stalked abroad in New South Wales and the more recently founded Tasmania, in consequence of floods of the river Hawkesbury, and subsequent failure of the wheat crop. The commencement of famine is, by one authority, put down as 1802, and he tells us how nobly the colonists of Port Jackson behaved to the famished and scurvy-stricken crews of the French vessels *Naturaliste* and *Géographe*, that sought shelter in that port. He tells us how "floods on the Hawkesbury had destroyed the wheat harvest, salt meat was exceedingly searce, and fresh meat almost unprocurable; yet so soon as the strangers' necessities were known, Government oxen were killed, and by common consent the ration of wheat issued to the garrison and inhabitants was reduced one-half, so that the scurvy-stricken crews might not want what was so essential for their recovery." This statement is made on the authority of a letter written by Baudin, who commanded the French vessels. Both he and Péron handsomely acknowledged the kindness they received, the affectionate care of Governor King, the courtesy and unremitting attention of the inhabitants, the generosity of the Government, and the absolute freedom accorded to their movements.

Verily, the conscript fathers of New South Wales proved then, as Australasians generally have since proved, that they had true old English grit in them.

It is with regret that I add, that Baudin's return for this unmeasured kindness was the seizure of Flinders when he put into Mauritius in distress a year or so later, and the appropriation of Flinders' log, charts, &c., descriptive of his explorations in the Southern Hemisphere.

As I have said elsewhere, those were very primitive times indeed in Australasia, and days when money, as well as provisions, was apt to fall short. In default of specie, goods and service—even service to the State—had to be paid for in produce or whatever substitute might be to hand. It is mentioned how, on one occasion, Governor King desired Governor Collins, of Van Diemen's Land, to pay for the carriage of despatches by a sealing ship by giving the skipper thirty salt-meat casks. Fortunately for those who kept the Government accounts, the days of rigid audit had not set in; but had there been a critical Auditor-General existing, one cannot but vaguely speculate as to the method of account which would have been adopted when the medium of exchange was indifferently an empty cask, or a bullock, or any other commodity that chanced to be forthcoming.

A curious chapter in the early life of Australasia was that arising out of the right of sovereignty which was claimed over this new colony and all the islands of the Pacific by the then all-powerful East India Company. This right was more than claimed, a strenuous effort was made to exercise it; and it is due to the interposition of Sir Joseph Banks that Australasia was not then and there recognised by the Home Government as the appanage and vassal of the East India Company.

It was in furtherance of this pretension that the East India Company, in 1794, sent Lieutenant Hayes, of the Bombay Marines,

to explore the coast of Van Diemen's Land and its harbours, and to return to India by the South Sea Islands and Malayan Archipelago. The Company held that their Royal charter secured to them an absolute monopoly of trade, not only with India and China, but with the entire East, including the whole of the Pacific Ocean. So exclusive were the privileges asserted, and so jealously were those privileges maintained, that, according to the East India Company, the colonists of New South Wales could not trade with England except by permission of the Company.

As late as 1806, the Company successfully resisted the sale in England of the first cargo of whale oil and seal skins, shipped from Sydney in the *Lady Barlow*, on the ground that the charter of the colony gave the colonists no right to trade, and that the transaction was a violation of the Company's charter, and against its welfare. It was urged, on behalf of the Court of Directors, that "such 'piratical enterprise' must be at once put a stop to, as the inevitable consequence of building ships in New South Wales will be an intercourse with all the ports of the China and Indian seas, and a population of European descent, reared in a climate suited to maintain the energies of the European character, which, when it becomes numerous, active, and opulent, may be expected to acquire the ascendancy in the Indian seas."

It was decided by the Lords Commissioners of Trade that the action of the colonists was an infringement of the East India Company's Charter; but Sir Joseph Banks interested himself on behalf of the colonists, and represented to the Court of Directors that, in future cases, the Lords Commissioners "are disposed to admit the cargo to entry, in case the Court of Directors see no objection to this measure of indulgence towards an infant and improving colony; and, further, that their lordships intend, without delay, to prepare instructions for the future government of the shipping concerns of the colony, on a plan suited to provide the inhabitants with the means of becoming less and less burdensome to the mother country, and formed in such a manner as to interfere as little as possible with the trade resources and prerogatives of the East India Company."

Marvellous are the changes which the whirligig of time has brought about in regard to these contending powers. In 1806, there was an all-powerful Company, with sovereign rights over millions of the people of Hindostan, which it exercised as autocratically as any tzar or kaiser, even to the extent of inhibiting the entrance into India of any Englishman without a license. A Company that, here in London, had its Court of Directors (not a mere Board), and had, at its court, its courtiers, suitors, and hangers-on, after the manner of some pinchbeck St. James's. A company that had, in India, an army and navy, and which was served there by men of world-wide fame, such as Clive and Warren Hastings. A Company, finally, which, when it wanted money from its Eastern Empire, did not seek it, as Australasia now does, unsuccessfully, by legitimate methods, but ordered it to be sent; this brave court, in one instance, it is said, wording its order in the Horatian lines, *Rem, facias rem; si possis recte, si non, quocumque modo rem.*

On the other hand, there was, in 1806, the "infant and improving colony," as Sir Joseph Banks described it, struggling for bare existence against famine and mutiny, and the many difficulties inseparable from the first settlement in a strange land, with a total white population of some ten thousand, and an external trade confined to whale oil and sealskins; no hope of getting money remitted for its use by any method whatever, and no great public servants to make it famous, except the early explorers, whose services had come to be forgotten, and Cook, who was remembered for other discoveries than that of Australia.

And now the all-powerful Company has, for thirty-three years, ceased to exist. Gone are its court, its army, its navy, its great proconsuls, and its despotic rule—so completely gone, that a generation has succeeded them which knows of those things only as ancient history. No longer can an Indian kingdom be wrested from its rightful owner by a forged treaty, or a Begum be made to ransom herself by more than her weight in gold; or a province be huckstered to enrich the great Company in England. Nawabs and Rajahs are no longer the abject feudatories of a sovereign trading corporation, and no more is it practicable to raise money *quocumque modo*, or to question the right of Australasia's colonies to trade with England without the Company's permission.

On the other hand, "the infant and improving colony" of 1806 has developed into the congeries of States known as Australasia, and, although only barely adolescent and still improving, is a power to be reckoned with. But although the provinces of Australasia

have now a trade of £140,000,000, although they have done some considerable shipbuilding, they have never carried their "piratical enterprises," as the East India Company styled their trade, into all the ports of China and India with the result, foreseen by that monopoly of piracy, of acquiring the ascendancy in the Indian seas.

I will indicate here by a few facts the slowness of the progress made, and the hardships endured, by New South Wales during the early part of her career.

On the 4th of May, 1790, every adult person in the settlement was put on a weekly allowance of 3 lbs. of flour, 1½ lbs. of beef, and 1 lb. of rice, children under twelve receiving half rations. The Governor (Phillip) had the same allowance, and officers invited to dine at Government House were required to bring their bread with them. This governor of Barmecide feasts informed a friend, "that he had lived in the colony for three years in the constant belief that he would some day perish of hunger."

In 1792, after four years, there were 208 acres in wheat, 1,180 acres in maize, 121 acres in garden stuff, and 185 acres of other land cleared. There were 105 sheep in the colony, valued at £10 10s. each, and 23 head of cattle, 11 horses, and several pigs.

In 1793 there fell upon New South Wales the blight of a sordid travesty of Cromwellian rule, which lasted until 1810. In 1793 the first act of the new Governor, Captain Grove, one time of the New South Wales Corps, was to transfer all authority hitherto held by five civil officers to the military officers of his late regiment. Fostered by Grove, the New South Wales Corps established for themselves a monopoly of trade, and especially of the sale of the then powerful medium of exchange—rum. They became known, indeed, as the "Rum-selling" corps. This justice-administering and spirit-retailing regiment were the terror of the settlers, and a scourge to the governors. Governor Bligh, who had quite a talent for creating mutiny, was deposed and deported by these imitators of Cromwell in 1806. Governors Hunter and King were harassed and defied by them, but in Governor Macquarie they found their master. He was the Constantine of this Prætorian guard that would have sold a diadem, as readily as rum, if there had been one. Immediately after his appearance on the scene the military rule of the New South Wales Corps was brought to an end, the regiment was ordered home, and replaced by the 73rd, the commandant cashiered, and the paymaster prohibited from living in the colony for eight years.

In 1795, new settlers on the Hawkesbury had 6,000 acres of wheat and maize under crop, and three rams and five ewes were imported, for which it is claimed that they formed the foundation of the sheep-farming industry of Australia. At that time prices ruled as follows: — A cow £80, horse, £90, sheep £7 10s., breeding sows £5, geese and turkeys £1 1s. each, ducks 10s. a pair, mutton 2s. a lb., goats' flesh 1s. 6d. a lb., butter 3s. a lb., green tea 16s. a lb., raw sugar 1s. 6d. a lb., and soap 2s. a lb.

During the first decade of the nineteenth century, *The Sydney Gazette*, the first Australian paper, appeared.

From 1810 to 1821 Governor Macquarie administered the affairs of New South Wales with admirable efficiency and success. During those eleven years the colony was quietly progressing, happy in that it had no history, and the esteem in which this governor was held may be, to some extent, gauged by the frequency with which one meets his name throughout Australasia. Now and again he said or did little things that irritated his subjects. The free settlers were annoyed at the extent of the hospitality he showed to those of the convict class. Doubtless, they resented his dictum "that colonial society consisted of two classes—those who had been transported, and those who ought to have been," but on the whole they were well satisfied with him, and named their rivers, and towns, and streets and harbours, after him accordingly.

From 1788 to 1803 New South Wales continued to be the one sole colony of the Australasian group. In the latter year Tasmania was founded, and Tasmania owes her position as the second colony in point of age to the fact that Port Phillip (*i.e.*, practically Melbourne) had been inspected and reported as unsuited for settlement.

Governor King is said, with some show of reason, to have been hurried into the seizure of Tasmania (then Van Diemen's Land) by the fear that that very taking person Baudin, after he and his crews had been nursed back into health and had taken his departure from Sydney, might be beforehand with him. My own impression, after studying the whole evidence, is that Baudin had no such design. At all events he made no effort in that direction, and left the field open to the British governor, whose lieutenants in a leisurely way took possession

of the "Garden Island" and started a settlement at Risdon Cove on the Derwent.

There was reason why this operation should have been undertaken in a leisurely way, in the condition of the local fleet, of which we read: "His Majesty's vessels in those seas were few in number, small, and often unseaworthy, and there was a constant difficulty in finding vessels that could be spared for any special service. Of those under Governor King's orders, the *Buffalo* was essential at Port Jackson, the *Lady Nelson* was off North with Flinders, the *Porpoise* (the only other ship of His Majesty) was away at Tahiti, salting pork for the necessities of the colony. But there was in Port Jackson a little armed schooner called the *Cumberland*, which had been built at Sydney a few years before for the purpose of pursuing runaways. She was only of 29 tons burden, it is true, but she would serve. This little craft was, therefore, hastily prepared for sea, a crew was selected, Lieut. Robbins, master-mate of H.M. ship *Buffalo*, was put in command, and in four days she was ready to sail."

But Lieut. Robbins' expedition was of the character of the up-hill march of the French King. He started to annex Van Diemen's Land; he halted at an island in Bass' Strait, turned into Port Phillip to find it was worthless, and then went back to Port Jackson.

Lieut. Bowen was the actual founder, and for some short time Commandant and Superintendent of the Risdon settlement. As befitted one with so expansive a title, he set out from Port Jackson for his satrapy with a fleet of two ships—the brig *Lady Nelson* of 60 tons, and the British whaler *Albion* of 326 tons. So, with his army of lance-corporal and seven rank and file of the New South Wales Corps, a civil service of three (including himself), six free persons and twenty-four convicts for subjects, one horse, ten head of cattle, about fifty sheep, a few goats, pigs and fowls, and six months provisions, Commandant and Superintendent Bowen founded Tasmania; and, curiously enough, another Bowen (Sir G. Bowen) fifty-six years later founded Queensland as a colony separate from and independent of New South Wales, at which time, as you may have heard from Sir George, there were 7½d. only in the public treasury of the new State.

Tasmania, founded 15 years later than New South Wales, and started in life as a convict settlement-at-ease to Botany Bay, very early in her career went through some of the roughest experiences of pioneers. In 1807, she shared with the parent colony the trials resulting from another flooding of the Hawkesbury and failure of the grain crop. Through 1808-9, the Tasmanian colonists made the intimate acquaintance of want and scarcity, if not famine; and, when relief came, in 1810, it was in the form of wheat from India. As for New South Wales, this is how General Macquarie, the newly-installed governor, reported of her condition, in 1810:—"I find the colony barely emerging from various privations and disabilities; the country impenetrable, beyond 40 miles from Sydney; agriculture in a yet languishing state; commerce in its early dawn; revenue unknown; threatened with famine, distracted by faction; the public buildings dilapidated; the few roads and bridges almost impassable; the population in general depressed by poverty; no credit, public or private."

Very early in their career, too, and for many years, the Tasmanian settlers suffered sorely from the treacherous and cruel attacks made upon the defenceless and isolated settlers by the native blacks, who resisted every effort to bring them within the pale of civilisation as obstinately as they resented the notion of keeping themselves entirely aloof from the white intruders. Doubtless, there were many errors, and some cruelty, on both sides, in the conflict that prevailed between the two races. On the part of the aborigines, the depredations, the raids, the murders of unarmed men and helpless women assumed such terrible proportions that, in 1830, the Government intervened. At a cost of £30,000, the Black Line was organised, with the object of forcing all the natives into one locality (Tasman's Peninsula), and with the result that a man and a boy were captured. £15,000 a head were expended upon these twain.

But, between 1830 and 1835, one philanthropist (George Robinson) accomplished, by kindly suasion, what all the force of the Government failed to achieve. He induced the remnant of this race to seek with him the asylum offered on Flinders Island; that remnant numbered 203 only. And, although these unfortunates were cared for with all necessary tenderness and forethought, they rapidly died out, and now there is no survivor of these people. They are as extinct, after 90 years contact with the English, as the moa or the mastodon.

If the Tasmanian pioneers did not experience, as New South Wales did in 1804, the

trials caused by an outbreak of the convicts, they were troubled a good deal through the first thirty years by the escapees from the Macquarie Harbour penal stations. Bushrangers of greater or less fame or infamy, and with greater or less leaning towards homicide as a casual amusement, roamed the land from "Brady's look-out" in the north, to other brigands' points of observation in the south, and east, and west. The peaceful settler who left his wife at morn in fear and trembling lest the blacks should spear her in the daytime, sat in his ingle nook at night fully alive to the possibility of a gun-barrel entering his window and the order to "bail up" reaching his ears from the bushranger outside. Happily, the bushrangers have died out as completely as the aborigines.

Tasmania's career as a subject province of New South Wales expired in 1825, when she was proclaimed an independent colony. She had turned to the fullest account the twenty-two years of her dependency; had so far progressed in agriculture that she was able to send 15,000 bushels of wheat to Sydney in 1816; had seen three public journals launched only to collapse; had built her first church; and had acquired a Supreme Court (1824), with a Judge from England. When made an independent province, she obtained a form of self government by an executive council of four members and a legislative council of seven.

Tasmania, happily, escaped from the distress that fell upon New South Wales in 1822, as a consequence of another flood in the Hawkesbury. Governor Brisbane distinguished himself in that crisis by directing the settlers not to pull up their cabbage stalks, but leave them in the ground to sprout again. Unfortunately, he distinguished himself in a more seriously compromising manner by attempting to depreciate the local currency—that last and worst expedient of incapable financiers—and this brought down upon him the censure and disapproval of the Home Government. But Brisbane lingered on in his governorship until 1825, when he was recalled in consequence of the dissatisfaction of the colonists. This was the first instance in which the Home Government admitted the right of Australia to have a voice in regard to the removal of an unpopular governor; and provided that this much be conceded, it should, I think, be admitted that the right of appointment rests solely with her Majesty's English advisers.

In 1823, New South Wales saw the last remnant and relic of her Prætorian guard disappear; the old military court was superseded by a supreme court, after the English fashion. Trial by jury was granted; and the Royal veterans, the waifs of the New South Wales corps left in the colony, were disbanded.

In 1824, New South Wales acquired her Legislative Council and freedom of the Press—a freedom that I may say has, with few exceptions, been thoroughly respected. In that year we find it noted that wool exports had increased from 100,000 lbs. in 1820 to 500,000 lbs.

In 1827-30, New South Wales experienced the first recorded drought of a serious character, and the needs of that colony had to be met by wheat imported from Tasmania.

In 1828, a census of the New South Wales population was taken, and her people numbered 36,598.

Having now glanced hurriedly at the early history of the parent colony of Australasia and her first scion, Tasmania, I will proceed to show, in their order of settlement, the other five colonies of the group.

1. New Zealand was first colonised from New South Wales, but I find two dates given in this connection—1814 and 1826; missionary stations had been established, however, as early as 1804. She was separated from the mother colony in 1840, from which year she was largely colonised from Great Britain by the New Zealand Company and others.

2. Western Australia was never attached to New South Wales. She was colonised from England as the Swan River Settlement in 1829, and a penal establishment existed there from 1851 to 1868.

3. Queensland, first colonised as Moreton Bay, and as a penal settlement attached to New South Wales, was made a separate colony in 1859.

4. Victoria was colonised by Tasmanians in 1834 as a part of New South Wales, and separated from her great rival in 1851.

5. South Australia, like Western Australia, has never formed a portion of the colony of New South Wales. She was colonised by British emigrants in 1836.

It is unnecessary, and, indeed, impracticable within the limits allowed to me, to follow the early fortunes of all these colonies. The early settlers in each, experienced in a lesser degree the hardships, perils, and occasional reverses that have been described as incidental to the colonisation of New South Wales; but these

may be left to your imagination. As to New Zealand, however, the case is different, as, indeed, is that colony different in nearly every respect from the continent of Australia. In its physical characteristics, its native population, its climate, its fauna and flora, New Zealand, justifying its position in another hemisphere, is essentially unlike Australia—so is its early history.

New Zealand was first seriously colonised by the New Zealand Company in 1840. Shortly after this somewhat grasping corporation had embarked on their colonial enterprise, Captain Hobson was sent out by the British Government to act as consul, and put some check on the Company's ambition, which, at that time, seemed to aim at sovereignity in this region. Captain Hobson shortly after his arrival proclaimed New Zealand a part of the colony of New South Wales, and it remained a dependency of New South Wales until November following, when it was proclaimed a separate British colony, Hobson ceasing to be consul and becoming governor.

But the English in New Zealand had to deal with a native people very superior to, and much more formidable than, the Australian blacks, and very shortly difficulties arose out of the not too clean-handed land purchases made by the New Zealand Company. In 1843, the Wairu massacres occurred, nineteen Europeans being killed in an attempt to serve warrants on the Chiefs Rauparaha and Rungiaiata. In 1845, Captain Fitzroy conducted a series of expeditions against the Chiefs Haki and Kamiti, with ultimate triumph to the British arms. In 1856, the Maoris set up a king, and demanded in his name the rights of government—New Zealand Home Rule in fact, and out of this movement arose a series of engagements in Taranaki that lasted over a year. In 1861, the Waikatoo war, directed against the claimants of sovereignty, was fought out. And the cost of the several wars in money alone was £10,000,000 sterling.

It may be safely assumed, and it is certainly to be ardently hoped, that there will be no further calamity of this sort. The Maoris, a people of high order of intelligence and many virtues, are thoroughly amenable to civilisation. They have proved this. They have shown that they are capable of worthily occupying a place, side by side with Englishmen, in the Legislative Assembly, or wherever the councils of the nation may be held, and with every year of intercourse the gulf that divides the whites from the coloured men is narrowing, and the old race antipathies are fading away.

It is estimated that when the English took possession of New Zealand there were 100,000 Maoris. In 1856 there were 65,000. In 1874 the number had dwindled down to 45,740, and it was said that the race was rapidly dying out. But recent figures show that while in 1886 there were 41,432, in 1891 there were 41,523, and that, therefore, it may be hoped that these interesting people are not to disappear, save by the admixture of races that has already commenced through marriage between Maoris and English.

Before leaving New Zealand, it should be mentioned that she was the first colony to embark in an heroic loan policy. In 1876, the Parliament of New Zealand adopted the following scheme, which was to be carried out by loans of some £10,000,000, viz.:—(1) Systematic immigration on a large scale; (2) construction of a main line of railway through the north and south island; (3) purchase of native land in the north island; (4) supply of water on the gold-fields; and (5) extension of telegraphic works. Sir Julius Vogel was sent home, in 1875, to negotiate £4,000,000 of this loan in England, and did so successfully. What, I wonder, would be the reception here at this time of any Australasian statesman who asked for a loan of £4,000,000, for any purpose whatever—even for public works of a decidedly reproductive character?

Fully responsible and constitutional government was conceded as follows:—Tasmania led the way, in 1855; New South Wales and Victoria followed in that year; New Zealand and South Australia obtained this boon in 1856; Queensland carried hers with her when she separated from New South Wales in 1859; and Western Australia acquired it in 1891.

Three of these seven colonies had been established by the British Government as penal settlements. Transportation to New South Wales was continued up to 1839, and to Tasmania up to 1853, both these colonies having made a strenuous fight to obtain relief from this incubus. In Western Australia, where no such opposition was shown, transportation lasted up to 1868. During the time that the system existed, there were transported to the three colonies 116,842 males and 20,139 females, or a total of 136,981, at a cost to the State of some £8,000,000.

Seeing that this total is equal to about 3½ per cent. of the whole population of Australasia, it might be assumed that there would be

in that population some of the taint of convictism. But this is distinctly not the case. Australasia is singularly free from that criminal class which in England stands out so distinctly defined from the general community. Criminals and offenders are there, as they are in every land where the law places restraint upon human action; but the crimes and offences committed are for the most part the consequence of an occasional lapse, and very rarely due to confirmed habit or life-long training.

It does not seem to me very difficult to explain this immunity from the heritage of convictism. There are two reasons for it that are conclusive to my mind (1), because the majority of those who were transported were not confirmed criminals, if, indeed, they may be styled criminals at all, but offenders to whom reform was as easy as it was welcome, and (2) because, as a rule, those who were beyond reform were also beyond anything like domesticity; liberty to them was not to be limited by the obligations due to any fixed abode or family. They wandered whither work was to be had. They went in rushes to the gold fields; the hollow log, or miner's tent, or farm out-house, where they laid their head was all the "home" they knew or cared for; and thus they went their way working for their daily bread—working out their salvation let us hope—doing but little harm to any man, and dying without an heir to any criminal instinct that may have been in them.

As to the first point, let me quote Sydney Smith, who closely studied this subject of transportation. This is what he says:—"Men are governed by words, and under the infamous term convict are comprehended crimes of the most different degrees and species of guilt. One man is transported for stealing three hams and a pot of sausages, and in the next berth to him on board the transport is a young surgeon who has been engaged in the mutiny at the Nore; the third man is for extorting money; the fourth was in a respectable situation of life at the time of the Irish Rebellion, and was so ill-read in history as to imagine that Ireland had been ill-treated by England, and so bad a reasoner as to suppose that nine Catholics ought not to pay tithes to one Protestant. Then comes a man who set his house on fire to cheat the Phœnix Office; and, lastly, that most glaring of all human villains, a poacher, driven from Europe, wife, and child, by thirty lords of manors, at the Quarter Sessions, for killing a partridge. Now, all these are crimes, no doubt, particularly the last; but they are surely crimes of very different degrees of intensity, to which different degrees of contempt and horror are attached, and from which those who have committed them may, by subsequent morality, emancipate themselves, with different degrees of difficulty, and with more or less success. A warrant granted by a reformed bacon-stealer would be absurd; but there is hardly any reason why a foolish, hot-brained young blockhead, who chose to favour the mutineers at the Nore, when he was sixteen years of age, may not make a very loyal subject, and a very respectable and respected magistrate when he is forty years of age, and has cast his Jacobin teeth, and fallen into the practical jobbing and loyal baseness which so commonly develops itself about that period of life."

Then as to another class of convicts—the agricultural followers of Swing, who resorted to rattening and machine breaking when the new threshing-machines were introduced; and as to the number of this class that fell victims to their violent outbreak, Sydney Smith writes:—"The law is up and the judge is coming. Fifty persons in Kent are already transported, and will see their wives and children no more. Sixty persons will be hanged in Hampshire. There are two hundred for trial in Wiltshire—all scholars of Swing! I am no farmer; I have not a machine bigger than a pepper-mill. I am a sincere friend to the poor; and I think every man should live by his labour; but it cuts me to the very heart to see honest husbandmen perishing by that worst of all machines, the gallows, under the guidance of that most fatal of all leaders, Swing!"

There were, in addition to the classes above named, others who were not, strictly speaking, criminals—mere jail-birds, *e.g.*, there were the misguided men who resisted by force the introduction of labour-saving machinery in factories; soldiers who, in a momentary ebullition of temper, struck or abused a commissioned or non-commissoned officer; and those too energetic and too previous people, the Chartists, who were transported for advocating six points, whereof three, vote by ballot, abolition of the property qualification for M.P.'s, and equal electoral distincts, have become integral parts of the British political system; while two others—universal suffrage and payment of members—have been very generally adopted throughout the British possessions.

Is it not reasonable to suppose that many of these unfortunates should have had the desire, as they had the opportunity, of reforming in

their new world, when for them reformation only meant the reverting to the principles in which they had been reared, and which, until a fatal moment, they had practised?

But it was by immigration of free men, not by transportation of convicts, that these colonies became peopled. Whereas, from first to last, the number of convicts sent out was 136,981 only, we find that the number that voluntarily emigrated from the United Kingdom was, to the end of 1872, no less than 1,020,502, leaving the emigration of the last 19 years (for which accurate statistics are not available) out of the account.

The history of Australasia's immigration policy presents some curious features. Sir R. Bourke, as Governor of New South Wales (1831 to 1837), introduced the practice of selling country Crown lands at 5s. an acre, instead of granting them free, as had been done there and in Tasmania. The proceeds of these sales, he, as far as possible, devoted to the promotion of immigration. But in this policy he encountered the opposition of his legislative council, and, at the end of six years, there was expended upon immigration £91,167 only, out of £439,652 realised by land sales. Sir George Gipps (Governor from 1838 to 1846) was directed by Lord Glenelg to raise the price of land to 12s., but he was at the same time instructed in the following terms:—"If you should observe that the extension of the population still proceeds with a rapidity beyond what is desirable, and that the want of labour continues to be seriously felt, you will take measures for checking the sale of land even at 12s."

From this it would appear that, in Lord Glenelg's opinion, the supply of labour diminished with an increasing supply of labourers. To-day immigration is opposed by some sections of the community for just the other and more rational reason, that labour competition increases with an increase of workers. This latter view was confirmed by the experience of that time, for, immigration being persisted in, the scarcity of labour ceased. But this policy was carried out in the face of much opposition on the part of the colonists, who urged that the Imperial Parliament had no right, under Lord Russell's Act, "for the regulation of the sale of waste lands in the Australasian Colonies and New Zealand," to make it compulsory on New South Wales to devote half of the proceeds of her land sales to immigration purposes.

Assisted immigration has now ceased in all the Australasian Colonies except Western Australia, Queensland having discontinued it only a month or two ago. From first to last, these colonies have expended upon this system £10,601,743, mostly out of revenue. But can it be said that Australasia is fully populated even now, when, upon its 3,075,736 square miles, it carries a population of a fraction over the unit per square mile?

Think of the size of Australia, with its 7,750 miles of coast line, and 2,994,019 square miles of territory. Extending from 10° 39′ south in the tropics, to 39° 11½′ south latitude in the temperate zone, and between the meridians of 113° 5′ and 153° 16′ east longitude, it is more than twenty-six times the size of Great Britain and Ireland, nearly six times as large as India, and only about one-fifth smaller than the continent of Europe. Then let us add Tasmania, an island something smaller than Ireland, and New Zealand, four times the size of Tasmania, and we have Australasia as the term is generally understood.

And over this wide expanse, stretching through more than 36° of latitude from the north of Australia to the southern extremity of New Zealand, there are, necessarily, many gradations of climate. In the north we find sugar cane, bananas, pines, and other tropical and sub-tropical products of field and garden; then for some thousand miles a succession of rolling downs and plains, upon which sheep and cattle flourish abundantly in teeming millions; then, interspersed with pastoral runs, wide stretches of arable land, upon which maize and wheat are grown, and vineyards and olive groves flourish, and so into the garden island, and New Zealand, where one meets with another England and Scotland, and all the fruits of the earth natural to the mother country, but in greater profusion, and mostly of superior quality.

And in all the period antecedent to the gold discovery in 1850, Australasia was given up to pastoral and agricultural pursuits, but more particularly to the former. Nature had there provided all but boundless tracts of grazing land, and sheep, especially in good seasons, improved and multiplied upon the runs. Whaling and sealing in the earlier days rivalled the pastoral industry in New South Wales and Tasmania, but they were for a time only; and now Hobart, which was the largest whaling station in the southern seas, has but two vessels left where once she had nearly fifty, while Sydney has, I believe, not one.

There were necessarily many fluctuations in

the pastoral industry in Australia, where from time to time droughts wrought havoc upon flocks and herds. At times, too, there was a glut of stock, as, after three or four good seasons, there is to-day. But to-day the colonists know how they may dispose of their surplus sheep and beasts, by sending carcass meat to England in the cool chambers of the large ocean-steamers. New Zealand has shown how this may be done profitably, and year by year has increased the number of carcass sheep exported thus, until she has reached something like 2,000,000 in the year. Australia has been doing this also for some little time, and will doubtless increase her exports very largely. But in the old time—the good old Arcadian time—when miners and railways, and progress were not, as for instance in 1838 to 1846, sheep were boiled down for their fat, and realised 2s. 6d. to 5s. each, while not many years before that their value had been £10 a head.

In that pastoral era, Australasia jogged along quietly, and I suppose contentedly, doing without the roads and railways, churches, schools, hospitals, libraries, mechanics' institutes, &c., that are now to be found, to a large extent, wherever there are people to be served by the conveniences of civilisation. In a humdrum sort of way these colonies prospered, population and wealth increased; and, as a set-off for the absence of those blessings above referred to, there was the absence also of that British investor, with his cry "you have borrowed too much."

In 1851 came the great awakening of this slumbering land. Gold was discovered in New South Wales in 1850, synchronously with the turning of the first sod of the Sydney to Goulbourn railway—the first line of railway in Australasia. It was also discovered in the same year in Tasmania. In New Zealand it was found as early as 1842. But little came of these discoveries at the time; and Victoria, where gold was found in 1851, immediately took the lead as a gold producing colony, and largely revolutionised the social and commercial conditions of the whole group.

In 1851, the gold raised in Victoria was of the value of £580,548; in 1852, the value rose to £10,953,936; and in 1853, it reached the maximum annual yield of £12,600,084. The output for the six years, 1852 to 1857, was £67,283,748, with an annual average of £11,213,951. For the four years, 1858 to 1861, it was £35,732,388, with an annual average of £8,933,097. For the ten years embraced by the above periods the gross output was £103,016,136, with an annual average of £10,301,613.

The effect of this discovery, when the richness of the alluvial fields came to be confirmed and widely known, was marked and far-reaching. In 1852-3, people flocked to the gold-fields of Victoria from all the quarters of the earth. South Australia was largely denuded of her manhood, and thrown back some years. Tasmania similarly suffered, over 22,000 adult males out of about 40,000 leaving her for the new El Dorado. But Tasmania was largely compensated for this exodus by the abnormal prices obtained from Victoria for her produce (£20 a ton for potatoes, and so on for other produce), which caused the value of her exports to rise from £665,790 in 1851 to £1,509,883 in 1852, and (the highest point yet reached) £1,756,316 in 1853.

From 1857, the annual value of the Victorian gold out-put declined, and has, with occasional slight fluctuations, continued to decline down to the present time. For the decade 1862 to 1871, the total output was £59,341,232, the annual average £5,934,123. For the decade 1872 to 1881, ths total output was £39,084,352, and the annual average £3,908,435. For the nine years 1882 to 1890, the total was £22,980,924, the annual average £2,298,092.

But Victoria well used the opportunity afforded to her, by the sudden accession of wealth and people brought to her in the palmiest days of her gold mining, and has not suffered her fortunes to depend upon the quantity of gold raised within her borders. In the heyday of her gold rush, she gave attention to the development of her industries; she soon became a rival of New South Wales as a manufacturing colony, and, like California, she shows, and has for some time shown, a steadily increasing trade, even in regard to exports, *malgré* the decline of her gold out-put, by many annual millions. For example, while Victoria's exports for 1853, when her gold out-put was £12,600,084, amounted to £11,061,544 in value; they were £15,302,454 in 1873, when her gold out-put had fallen to £4,809,670. Victoria's pastoral industry developed while her gold out-put was slackening. When gold was discovered in that colony the wool exports were of a value below £1,000,000 sterling; in 1860, they stood at £2,025,066; in 1870, at £3,205,106; in 1880, at £6,417,466.

Other colonies, notably New South Wales, Queensland, and New Zealand, have, since 1851, produced gold in quantity; the total production for the various colonies from the com-

mencement of the gold mining to the end of 1889, having been as follows :—

	Oz.
Victoria	56,250,798
New South Wales	10,050,960
New Zealand	11,625,028
Queensland	6,873,314
Tasmania	565,222
South Australia	273,441
Western Australia	135,492
Total	85,774,255

The production continues, and if the splendid alluvial fields of Ballarat and Sandhurst, and elsewhere, have been largely worked out, new discoveries of quartz reefs and alluvial ground are being yet made from time to time, nor is it outside the range of possibility that gold mining may yet do as much, or more, for Australasia than it has in the past.

Gold does not exhaust our list of mineral discoveries. South Australia has worked the great Burra Burra, Moonta, and other copper mines to her profit. Tasmania, New South Wales, and Queensland have, since the gold discovery, raised considerable quantities of tin; Tasmania having from 1873 to 1889 exported tin of the value of £4,711,890, while New South Wales and Queensland have sent forth tin worth £13,222,047. Then, in 1885, the wonderful Broken Hill Mines of New South Wales brought silver into the list of Australasian mineral resources, while, even later in the day, the West Coast of Tasmania was proved to be, as to some hundreds of square miles, one large and rich silver field. Magnificent seams of coal have been worked for years in New South Wales. And Queensland and Tasmania now produce a fairly good coal in quantity more than equal to local requirements. Iron is known to exist, and only awaits capital to develop it: and bismuth, asbestos, and other minerals of commercial value are there, with gems from zircons to sapphires.

The value of the gold raised in Australasia up to 1889, at a price slightly less than £4 per oz., is £343,000,000. Add to that the values of tin, silver, coal, and copper exported £80,000,000, and we have a total of £423,000,000 for minerals produced, excluding coal, &c., consumed in the producing colonies and unnoted in available statistics.

The gold discovery, which electrified the people into a new life, and caused an economical development that has been as lasting as it is favourable, created a difficulty that has caused at times much anxiety and a little trouble. Among the crowds from all nations that came to the Victorian gold fields, were some thousands of Chinese, and from that day to this these Celestials have been with us in Australasia, principally as miners on poor ground that would not keep a European; largely as market gardeners, in which capacity they have nearly established a monopoly, and in other lines of handicraft. And being with us they have leaped into fame, much against their wishes and interest, as the creators of a Question. That Chinese question which has afforded work for our legislators in the way of prohibitive and restrictive enactments; which has set our Supreme Courts and the Privy Council in motion, and has caused the statesmen of the seven colonies to meet in solemn conclave, for the discussion of the ways and means by which the Chinaman may be excluded from Australasia.

It was objected, in respect to this Asiatic, that in any very large number he was objectionable. It was feared that hordes of these Mongolians had come or were coming. An import duty (or poll-tax) of £10 a head levied upon each Chinaman, was in some colonies deemed insufficient to keep him out, and a duty of £100 was introduced; other drastic measures were adopted, not always with the complete sanction of the law tribunals of the colonies, and, in short, the Chinaman became worse than a menace—he became a bore.

And really there does not seem to have been any reason for this access of Chinaphobia. Statistics certainly do not provide it, for whereas there were estimated to be 43,000 Chinese in Australasia in 1859, of whom 42,000 were in Victoria, there were only 43,706 distributed over the seven colonies, according to the Census of 1881; and by the Census of 1891 it is shown that this number has declined by about 3,000. As to the number in Victoria, that was 12,128 in 1881, and only 9,377 last year. It is true that an abnormal number (2,049) entered the colonies in 1887, and hence the conference; but this was only the fifth occasion since 1861 when the annual arrivals exceeded 1,000, and the average immigration of the five years preceding 1887 was 619 only.

The population of Victoria, which was in 1851 86,825, against 187,243 in New South Wales, rose in 1861 to 540,322 against 350,860 for New South Wales. This sudden bound was, of course, due to the influx of people to the gold fields, the miners, and the suttlers who followed the great mining army. But an increase almost as phenomenal, and general to

all the colonies of the group, has resulted from the more progressive policy inaugurated in the golden era. Thus we find the population of Australasia recorded at 1,237,684 in 1861, at 1,923,195 in 1871, at 2,742,550 in 1881, and at 4,000,101 by the Census of 1891.

These increases of the people have been accompanied by the development everywhere of old, and the introduction of new, industries, Manufactures unknown in the early days have, since 1851, gone on, always expanding, until now the out-turn from local factories has an annual value of several millions, and to that extent makes Australasia independent of the outer world. Viticulture has become established as an important factor in Australia's industrial system, and against 3,435 gallons of wine exported by South Australia in 1860, we have for 1890 exports from that colony of 221,850 gallons, Victoria having exported 214,016 gallons in that year, New South Wales 48,480, and the united colenies, including Queensland and Tasmania, 486,247 gallons. And when the British public shall have come to appreciate at their true value the Tintara, Hermitage, Frontignac, &c., grown in those Antipodean vineyards, these exports will be increased indefinitely.

But the omniverous British public has already given all possible encouragement to Australasia's new trade of meat purveying. Now when the cattle of Australasia have increased from 2,302,327 in 1850 to 10,346,661 in 1890, and sheep from 22,186,833 to 114,141,893, the stock owner finds an outlet in the meat market of England; and there is little chance of the supply failing, however greatly the demand may increase.

Australasia, in short, has turned her resources to account, and is in the way to become, as regards food supplies, the Whiteley of the United Kingdom. Most dutiful of Britain's scions, she is doing more than any other to feed her mother. It is not now-a-days, as of yore, the mere supply of wool and corn. Australasia continues to provide these in quantity, her last season's wool exports having touched the value of £25,000,000. But now she is teaching Britain to look to her for wine, and corn, and oil, for meat and fruit, and the produce of the dairy. Tasmania has achieved a name in the English market for her splendid apples, New Zealand has commenced to supply us here with peaches, apricots and nectarines, that are also produced in Tasmania in perfection. Australia and New Zealand have established a butter and cheese trade with England. The irrigation colonies, Renmark and Mildura, have commenced to supply raisins, and promise to follow with other dried or canned fruits. In Australia there are awaiting the English demand, olives and their oil, with many another tropical and sub-tropical product; oranges and lemons are coming in number from the groves of Paramatta. And if need were, Northern Australia could supply this market with sugar, that is now largely grown in Queensland and New South Wales, and, the coloured labour difficulty being surmounted, will be more largely grown in future.

May I be permitted to employ in regard to this labour question the boast, "I told you so." On the 8th December last, I ventured, at the Royal Colonial Institute, to express my conviction that Australia's resources would not be wasted in those northern regions, if coloured labour proved to be essential to their due development: that when the exigencies of the occasion demanded it, the opposition to that class of labour would be conquered. It very rarely happens that prophetic statements of this sort are immediately verified. In this instance verification in part has come with exceeding promptness, for before two months had elapsed after that vaticination of mine, the Premier of Queensland proclaimed his intention to propose the reopening of the sugar fields of his country to the full tide of Kanaka labour,* and the Premier of South Australia had set out on a tour to India with the intention of studying the question of employing Indian coolie labour upon the tropical area of his country.

The importance of the Australian sugar industry may be gathered from the fact that now, while yet in its infancy, the area under cane has grown since 1871 from 13,975 to 71,368 acres (viz. Queensland, 50,922 acres; New South Wales 20,446 acres), the produce of sugar being in 1891 about 95,000 tons. Doubtless the northern territory of South Australia and Western Australia will, in the course of time, add to the area of production.

Now the wonderful progress in Australasia's material wealth, that is hinted at rather than described above, is mainly due to that progressive policy which has had among its consequences a very great enhancement of the Public Debt. Australasia, with what I believe to be an admirable spirit of enlightenment and self-sacrifice, has anticipated a century of

* Since this was written, the Queensland Act of Parliament for extension of Kanaka labour for ten years has become law.

lagging growth; she has bridged over an abyss of time, and, at a cost which she bears ungrudgingly, has given to this generation of men those advantages and comforts of civilisation that in the course pursued during the first half century, their grandchildren would not have witnessed and enjoyed. They have made Australasia richer far by every test, and more productive (not excepting agricultural produce) than Canada, which has 25 per cent. more people, and more than double the period of existence. Could she have done this without discounting the future? The answer should be "No." But the financiers on this side—the holders of those purse strings that are now close drawn against Australasian borrowers—will possibly leave that question unargued and unanswered. They will only say "you have borrowed too much," and shout *Anathema Maranatha!* upon the Australias as so many daughters of the horseleech—although at the worst they are only asked to lend with the certainty of regular payment of interest and the best security for their capital.

Should it not be sufficient for British investors to know that the capital they have advanced is safe, and has been employed with remunerative results? Of the Australasian debt of £185,000,000 no less a sum than £121,000,000 has been invested in railways, whereas if the capital sunk in railways of the United Kingdom were added to the National Debt of this country, that debt would be swollen by £897,000,000. There is this difference to the investor in the two investments, that while the capital he puts into Australasian railways gives a fixed return of, say, 3½ per cent., whether the railways pay or not, that put into the railways of the United Kingdom yields only such return as the profitable working of the lines may afford.

Supposing, for the sake of argument, that Australasian railways gave no net profit, they would be largely reproductive in that they yield what has been aptly styled a "hidden profit" greatly exceeding the net profit of the best paying lines. The hidden value represents the time and money saved in transport of goods, and the larger productive areas opened up by means of improved communication. It is a value that is appreciated by the colonist who pays interest on our loans, in that it obviously increases his wealth as well as adding to his convenience.

But as a fact Australasian railways do yield a net profit to meet in whole, or in part, the interest charge. Those of New South Wales and Victoria have thus paid over 3 per cent. All the colonies contribute something to this end. South Australian lines pay 5.32 per cent r more than the interest upon their capital cost.

Certainly South Australia offers a most hopeful example of what Australasian public works may do in this regard. Witness the following statement from the account of the Commissioners of Audit for June, 1891:—

Net interest payable upon loans		£751,295
Railways—net earnings	£606,820	
Telegraphs, say	25,000	
Waterworks	65,167	
Adelaide sewers (contributed out of rates)	13,352	
Balance of interest payable out of revenue	40,956	
		£751,295

What South Australia has accomplished will doubtless be achieved by other colonies as progress and opportunity serve.

It may be added that South Australia, Victoria, and other colonies, have expended some millions out of revenue upon railways.

South Australia is one of the three Australasian colonies that have the heaviest debt per head of population. Does not the above statement prove that what is called debt in her case is only capital wisely employed, and as to 95 per cent. so reproductive that it imposes no burden upon the colony.

New Zealand is another colony that ranks as most deeply indebted to the British capitalist. She was, at one time, the shocking example in this respect, and there were many in the neighbouring colonies who could see nothing but ruin—certain and inevitable ruin—awaiting the extravagant Maorilanders. But what have been the results of this daring policy? I do not question but that there have been times of anxiety, and struggle, and retrenchment, when, perhaps, New Zealanders lost faith in the policy of progress, but those times have been survived, and, always advancing by leaps and bounds from decade to decade, New Zealand now finds herseif flourishing, and able to hold her own comfortably without the aid of the grudging purseholders, who tell us we have borrowed too much, and tell us this all alike, whether we have borrowed at the rate of £60 per head or £40.

What was New Zealand among the Australias prior to that time when the forward

movement took place. In 1850 she stood lowest of all the colonies, save Western Australia, in regard to population, exports, imports, cattle, sheep, bank deposits, &c. In 1890 she stood second as to sheep, third as to wool exports and bank deposits, and fourth as to the other items named. Her population during that period increased from 22,108 to 626,658, or 28 times; her bank deposits (from 1860 to 1890), 19 times; her imports, 26 times; her exports, 53 times; her cattle, 29 times; and her sheep, 113 times.

But let me make the larger comparison of Australasia as she was in 1850 and 1890 respectively. In estimating the present condition of Australasia, I do not dwell upon the wealth represented by millions of acres of unalienated Crown estate, that have a prospective value far in excess of the total of the Australasian public debt, or the present value of the Crown estate in the form of railways and other public works, which is more than equal to that debt. Nor can I compare the private wealth of 1850 and 1890 in the absence of figures for the former period; but I may state that, by a careful valuation made by the Government statist of New South Wales, the private wealth of Australasia was, in 1888-9, no less than £1,129,000,000, or a sum six times larger than Australasia's national debt, and then I may leave the following comparative statement to speak for itself:—

	1850.	1890.
Debt	£57,917	£184,912,804
Population	648,133	3,532,050
Wool exports*	£2,836,514	£23,734,332
Total ,,	£4,763,594	£70,901,685
,, imports	£4,619,930	£68,495,581
Number of horses	183,892	1,613,585
,, cattle	2,302,327	10,346,661
,, sheep	22,186,833	114,141,893
Shipping, inwards and outwards ... tons	1,209,515	15,395,186
Bank deposits (say)	£6,000,000	£110,855,571
Savings (approx.)	£1,500,000	£17,312,795
Minerals exported	Nil	£14,122,117
Revenue	£1,201,068	£29,306,217
Railways (miles)	Nil	11,600

And as to this statement, I will only remark that the increase in stock of the colonies alone represents a value equal to two-thirds of the national debt; and that while one item of private wealth does this, the State railways give to the Crown estate an enhanced value of the like amount.

* Wool represented more than half of exports in 1850, but less than one-third of those of 1890, when they had increased eightfold.

If Australasia has husbanded her resources and increased her possessions—to some extent out of British capital—she has amply proved her purchasing power and her trade value to the mother country. In a return for the years 1879 to 1888, Australasia ranks third (next to the United States and India) among the consumers of British products. Of the total British exports, 9·57 per cent. were taken by Australasia, while Canada took 2·89 per cent. And in this connection, if we take Australasia's imports of British goods per head of population, she stands absolutely first in rank, with £7 10s. 10d. per head, Holland coming second with £3 7s. 11d., and Canada third with £2 9s. 7d.

In some directions Australasia has, as I have said, commenced her career as a manufacturing country. To that extent she has ceased to be dependent upon the United Kingdom for manufactured goods; and, doubtless, as she advances in her industrial career there will be expansion of this internal production. She will require fewer products of the United Kingdom then than now; but that difference will be compensated by the increased demand of the residue necessitated by an increased population, and it is impossible to foresee a time when Australasia shall be entirely independent of the United Kingdom in this respect.

But her dependence upon the mother country as a market for her ever-growing produce, her wool, and wines, and corn, and meat, and metals, must continue through all the ages; or, putting it the other way, the mother country must continue to be largely dependent upon Australasia for these products. There is here a mutual interest that must be a bond of union always, and one may hope, a sufficient inducement to the Government of this country to keep clear of any treaty with foreign powers that may impose the slightest restriction upon commerce within the Empire.

In her own interest, Australasia could not be otherwise than faithful in her commercial obligations, and loyal to the mother country that is her best customer. But, as a matter of choice, and on purely sentimental grounds, she is as loyal as any portion of the Empire; and English to the core, as no other colonial territory is, I say she is loyal by choice, because there is no pressure from without, as there is in the case of Canada, to quicken her loyalty; no power at her gates to make a close alliance with Britain the necessary alternative of separation: she is moved only by an honest love for the land of her forefathers, and a pardonable pride in those

great traditions of our race which she inherits in common with brother Britons all the world over. And, in spite of the empty talk of fifth-rate colonial politicians, and the equally vacuous babble of certain English critics, I believe this loyalty and this brotherly love to be enduring.

"But," says the financial critic, to these colonial brothers, "you have borrowed too much; and I will lend you no more." Putting sentiment aside, as something excluded from the region east of Temple-bar, is this just or business-like? Who was it that encouraged the Australias to borrow so largely, and led them on, by offering two or three millions for every million asked for? I answer, the critics who to-day charge us with borrowing too much. They are as guilty as any one, if guilt there be in the business. Their pockets were overflowing with money, to be placed at Australasia's disposal, two years ago; and then, with the suddenness of the lightning-flash (but not with such irradiation), they announced that their hearts and purse strings were closed to us. Surely there is injustice in such a *volte face* as this, without a note of warning, so that those to be affected by the change might prepare for it.

And it is, I think, a mistake, from a business point of view. The British public have put some £190,000,000 into railways and other State undertakings of Australasia, which, after all, only represent a portion of the enterprises required. They have encouraged the Australasians to push on with a vigorous progressive policy that has worked wonders already in increasing the national wealth. They have embarked with us in a course that has been proved to be a prudent one, and to which, owing to British encouragement, the people of Australasia stand committed. Can it be deemed wise to arrest this progress at a moment's notice, for the sake of reading the Australasian people a lesson of economy? Is it not, as far as British capitalists are concerned, a starving of their investments which they would not countenance if their money had been sunk in some undertaking at home, which they would not so readily adopt as to Australasian undertakings were it not that their interest is safe whether those undertakings give a direct return or not. Their capital and interest are alike safe, I am convinced. There is ample security for both in the facts and figures I have cited as illustrating Australasia's resources. But that does not entirely relieve the British investor from his obligation as such, and I may add that I feel confident that the generosity, sagacity, and rectitude that distinguish this purse-holder will ensure his good faith when he sees what his obligation is.

I have no time, nor is there occasion now, to reply to those critics who have recently impugned the credit of Australasia in every possible or impossible direction. They are of that class of warrior which begins the battle when the foe is stricken down, and their attacks bring them little honour and convey no discredit. But I may be permitted to say briefly, that in spite of much misjudged occasional criticism of the manners, customs, and morals of the Australasians, these people compare favourably with others of the English-speaking race, that in spite of much that has been said against Australasia's financial and political methods, honesty of purpose and a true spirit of altruism have, as a rule, regulated the management of her affairs. There has been a good deal of carping at the extent of the people's power, and the manner in which ministries have submitted to this. But it may be urged that while Governments here, as there, are the outcome of the popular vote, the people there, owing to the wider distribution of wealth, are as a whole more truly Conservative, and more directly interested in safeguarding existing interests, than the masses of the United Kingdom. Ministries there ordinarily dictate the public policy and lead the people. Ministries here occasionally are led by the people instead of leading them, and, it should be added, without any permanent ill effects to the common weal.

The Australias are just now suffering from depression that has spread over the greater part of the civilised world. They are, for the moment, regarded with less favour than they were two years ago; but they contain all the elements essential to a great career, and the four millions of Englishmen who are toiling there are building up an empire that shall be ranked in the time to come second to none of the possessions that constitute the British Empire.

DISCUSSION.

Sir SAUL SAMUEL, K.C.M.G., C.B., said he could add but little of interest to the very exhaustive, interesting, and historical paper to which they had just listened, but as his experience with regard to the colonies extended over a period of sixty years, he might be permitted to make a few observations. He went to the colony of New Sou Wales in 1832,

and at this time New South Wales was all Australia; Victoria, New Zealand, South Australia, and Queensland not then being on the map of the world as colonies. He recollected when the heavy traffic of Australia was done by bullock teams. There were no horse teams in those days, for the roads were so very bad that horses could not do the work. The mails were conveyed in a very rude way, and it took about four days to go 100 miles. This distance was now done in as many hours. In those times it took five or six months to go from England to Australia, while now the voyage was performed in as many weeks, and, by means of the electric telegraph, we are in daily communication. All this showed what vast progress had been made—a progress unparalleled in the history of the world. Unfortunately, he had not had an opportunity of seeing the paper before coming to the meeting, or he would have been better prepared to speak upon it, but still, he might say there was much in it of history which showed the marvellous progress made by the colonies. He noticed a reference to the indebtedness of the colonies. It was said that the debt of the Australasian colonies was £185,000,000. Now, what had been done with the amount thus raised? How had England benefited by it? In consequence of the absence of navigable rivers in Australia, it became necessary in order to provide for the settlement of the country that it should be covered with railways, and no one in his senses would suppose that these railways and other great public works could have been constructed out of the revenues of the colonies. This was impossible. The colonies then availed themselves of the facilities which were afforded for borrowing money in the mother country for the purpose of making these railways, and with the object of settling the surplus population of England upon the lands of the colony. What had been the result of all this? When he went there 60 years ago the population was 53,000, now it was over 4,000,000. These were people who had gone out from the mother country, settled upon the lands of the colonies, and made a trade for England which she would not like to part with. One result had been that the shipping of the mother country had largely increased. In 1819, there was a regulation in England that no vessel under 350 tons should be allowed to go to Australia; the people in New South Wales were so alarmed at this, because it would take so long to load a vessel of that tonnage, that they met in public meeting in Sydney and petitioned the Government to reduce the tonnage by one half. Now vessels of 5,000 and 6,000 tons were entering the port of Sydney every week. All this had been brought about by the instrumentality of borrowed money, upon which the people of the colonies were well able to pay the interest. A strange alarm had been created, though why no one could tell, and people were not so ready to invest in colonial stocks as formerly. He had great faith in the colonies, and in the honour and credit of Englishmen, who he was sure would never break faith with their creditors. He felt convinced that before very long the colonies would be able to borrow with the same facility they did a few years ago. It was a most insane alarm that had taken possession of the minds of some investors, and it was brought about in a great measure by mischievous people and a portion of the Press. All this would correct itself in time if the colonies were only quiet, and did not show too great anxiety to again come upon the market with loans. If investors held back, they would soon find that the result would be injurious to England herself, as the expenditure by the colonies in this country would be considerably diminished. He was not at all certain that English manufacturers were not beginning to suffer in this respect already. He hoped the English people would soon begin to realise that they could not have a better investment than in Australasian securities.

Mr. E. B. TREDWEN said he wished to point out the valuable nature of the security upon which British investors were asked to lend to the Australasian securities—viz., the security of the railways. When railways were constructed here they were constructed under Acts of Parliament, which limited the rates that could be charged, but in the colonies they were constructed by the State, and worked with the view of simply developing the country by inducing people to settle on the land. If the railways in the colonies had been constructed by private enterprise, there would not be the low rates which were at present charged, but rates would be charged so as to make the scheme remunerative. He felt sure that if the colonies had to realise their securities to pay their creditors, that the railways could be floated at such a price as would enable them to pay off the whole of their debts, because those who purchased the lines would be enabled to charge a rate for the carriage of goods which would at once show a remunerative profit upon the working. He thought this was a fact which ought not to be forgotten by English investors.

Sir JOHN BRAY, K.C.M.G., said, so far as Australia was concerned, he thought the colonists were too much depressed with the fact that they had not been able to float loans so successfully during the last few months as formerly, though, on the whole, he thought the money had been profitably invested both for the colonies and for the English people. Australians were English, and their interest was the same as the mother country. The railways had produced a net revenue of $5\frac{1}{2}$ per cent. after providing interest upon the money borrowed and for working expenses, so that they must be considered a good security for the money lent. No doubt the returns from a railway, to some extent, depended upon the season and the goods carried, but, upon the whole, he was convinced that the railways had been constructed with judgment for the benefit of the people

living in different parts of the colony, and for the advantage of those who had provided the capital. He trusted that the people of England would take greater interest in Australia than they had done in times past.

The Hon. J. MUNRO (Agent-General for Victoria) said the paper was a valuable addition to the literature of the previous history of the colonies, but he was much more interested in their present condition than in what occurred sixty years ago. He was not sure whether he understood Sir Edward Braddon correctly, but it appeared there was a mistake in the paper, historically, with regard to the borrowing of the different colonies, for, as he gathered, Sir Edward Braddon stated that Sir Julius Vogel was the first to borrow money on behalf of New Zealand.

Sir EDWARD BRADDON said the statement in the paper was that New Zealand was the first colony to embark on an heroic policy.

The Hon. J. MUNRO said that Victoria borrowed £10,000,000 for railway construction before New Zealand.

Sir SAUL SAMUEL said New South Wales had done the same.

The Hon. J. MUNRO said upon their loan Victoria had to pay 6 per cent., but the money had been made good use of. If the colony did not borrow any more, the existing contracts having been carried out, the result would be that she would cease to import, and British manufacturers would in consequence suffer thereby. He was quite sure that the Australian colonies, if they were simply cut off from the rest of the world, would be quite able to support themselves. They had a variety of soil, manufactures, and minerals, owing to which the colonies were quite able to get on without any assistance. It had been said that the colonies were extravagant in their borrowing, but taking the colony of Victoria as an example, it appeared that they had borrowed £44,000,000, and had spent £45,000,000 upon the construction of railways. About £35,000,000 from loans, and £10,000,000 from revenue. A greater sum than every shilling borrowed had been spent on railways, and yet they were told that they were going too fast in this direction. He was sure that those who said so did not understand the position. Had railways not been made, the land would have been unproductive. Of one thing he was convinced, and that was that there was no chance of the colonies ever repudiating their loans. In England, people were taxed in every direction, but in the colonies there was no such thing known as Income-tax, and in Victoria £450,000 a year was devoted to the making of roads. If the colonists were put to it they could increase the revenue very much indeed. For a population of but 1,140,000 a revenue of £9,000,000 or £10,000,000 was by no means a small amount, but if necessary this sum could be increased to over £10,000,000. If English people thought the colonies ought not to borrow any more money, they must share the consequence of so thinking with the colonies, for if money was not lent, the imports would be considerably diminished, the result being a serious loss to British industry.

Sir PHILIP CUNLIFFE-OWEN, K.C.B., K.C.M.G., said that, although he very much regretted that this country was still without a Colonial Museum, this regret would soon be removed when the Imperial Institute was completed. The fact was that English people were rather afraid of the producing power of the colonies, and although they did not like to say so, because they knew they were their best customers, yet secretly they felt that the colonists were manufacturing on their own account, and with so much success that the middleman was first of all doomed, and, what was more, some of the manufacturers were doomed. The general opinion of Englishmen was that Providence had created the colonies in order to provide a market for home productions, and they did not like the idea of the colonies producing for themselves. They think it is improper, and accordingly are determined to stamp out all idea of a Colonial Exhibition. The English people were somewhat ignorant of what was going on in the colonies, but a few more papers like that to which they had listened that evening would go far towards letting them know what was going on.

Sir JAMES GARRICK, K.C.M.G., said, listening to the paper had reminded him of the great success which had attended the efforts of the Chairman in the inauguration of the colony of Queensland. At the present moment the colony was passing through a time of difficulty, but he thought the Chairman would remember that the colony, five or six years after its birth, went through a time of difficulty—far greater than that which now presented itself—but within a few years it arose from its difficulties and became exceedingly prosperous. In 1866, when they were much pressed, they had to have recourse to Treasury bills, and they went upon the market as ordinary borrowers, paying interest at the rate of 10 per cent. With the money thus obtained the resources of the colony were helped to be developed, and Queensland soon occupied the proud position of being one of the greatest colonies. If they had got into debt, England derived a great deal of good from it. The foreign trade of England had shrunk during many years, while the trade with the outlying portions of its empire had increased by leaps and bounds. Queensland itself had, out of a population of some 400,000 people, sent about 200,000 souls from this country with borrowed money, and this had been a most profitable investment, for the people had been amongst England's very best customers. They had built up a colonial trade for England

amounting to millions a-year, and if that trade were capitalised, a financier would tell them that the value was greater than all the money which had been lent. It was a very common thing to compare Queensland with some of the old countries, and to say that the debt was greater per head than in other places, but this was a fallacy, for it must not be forgotten that the colonies had no debt for wars. Nearly all the debt was a productive one, and in estimating whether a nation was indebted more than another it was fallacious to place the debt at so much per head. In the colonies the railways and public works belonged to the State, and this fact had been entirely overlooked by those who referred to the capitation debt. He did not say that possibly the Australian colonies had gone into debt a little too fast; they might have sought to develop the country at a greater rate than they ought to have done, but that was simply a question of rest. He knew no country in the world that would recuperate faster than Australasia. Part of their difficulties had been brought about by those of the South American Republics. The Anglo-Saxon was altogether a different person from the people who inhabited the South American Republics; and further, it must not be forgotten that rebellions and revolutions were unknown. If England were to impress the colonies with the idea that they were going too fast, the result would be that they would rest and grow strong. The colonies had no idea of repudiation. In fact they would tax themselves to the very last shilling in order to pay their debts. In future he had no doubt the colonies would endeavour to lean less on England than before, and one result of this would be that English manufacturers would suffer. The trade of England with the colonies had already fallen off. He was sure the colonies had enough energy and honour never for a single instant to lose sight of the engagements which they had made with their fellow-countrymen in England.

The CHAIRMAN, in proposing a vote of thanks to Sir Edward Braddon, said this was not the first occasion on which that gentleman had obliged the Society of Arts with a paper, and he trusted it would by no means be the last. The audience must have admired the able manner in which the paper was put together, as the long historical statement was interspersed with touches of dry humour, which made it extremely light, notwithstanding that it was loaded with statistics. During part of the time he (the Chairman) was Prime Minister of Queensland the colony was in difficulty, as had been stated by Sir James Garrick, but it very quickly recovered itself, and soon became again one of the most prosperous colonies. His own opinion was that English people need not have the smallest anxiety with regard to Australian investments.

The vote of thanks having been carried, was briefly acknowledged by Sir EDWARD BRADDON.

INDIAN SECTION.

Thursday, April 28, 1892; SAMUEL SMITH, M.P., in the chair.

The paper read was "Re-organisation of Agricultural Credit in India," by Sir WILLIAM WEDDERBURN, Bart.

The paper and report of the discussion will be printed in the next number of the *Journal*.

NINETEENTH ORDINARY MEETING.

Wednesday, May 4, 1892; WILLIAM HENRY PREECE, F.R.S., Member of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Bamber, M. Kelway, Seleng, Jorehat, Upper Assam, India.
Griffith, Frank, Prujean-square, Old Bailey, E.C.
Grimes, Arthur John Luna, Telegraph Department, Bombay, India.
O'Connor, John, M.P., House of Commons, S.W.
Townend, James Hamilton, Haberdashers'-hall, Gresham-street, E.C.

The following candidates were balloted for and duly elected members of the Society:—

Chorlton, Thomas, 32, Brazenose-street, Manchester.
Hill, Lieut.-Colonel John, R.E., Poona, India.
Holzapfel, Albert C., 57, Fenchurch-street, E.C.
Lowenfeld, Henry, 31, Lowndes-square, S.W.
Ryder, Charles, Gledhow-hill, Leeds.

The paper read was—

THE BRADFORD CORPORATION ELECTRICITY SUPPLY.

By JAMES N. SHOOLBRED, B.A., M.Inst.C.E.

In the early part of 1888, the Corporation of Bradford, responding to the expressed desire of a number of their ratepayers, decided to provide a supply of electricity, in accordance with the Bradford Electric Lighting Provisional Order, 1883, for that portion of the centre of the town which had been approved of by the Board of Trade, under the title of the "Compulsory Area" of the Order.

The preparation of the plans, and the superintendence of the works necessary to carry out the above decision, were entrusted to the

author, who, as the consulting electrical engineer of the Corporation, had acted as their technical adviser throughout the earlier stages, while obtaining their Provisional Order.

After mature and careful consideration, it was decided to adopt the system of continuous current, generated at low pressure, and distributed direct to the houses on the two-wire parallel arrangement (at first, at least), but this arrangement could, later on, with the increase in the demand as well as in the distance of the distribution, be so modified as to meet those requirements.

In arriving at this decision, it was felt that the "continuous" current offered a number of industrial applications, such as motive-power, electro-deposition, storage, and others, peculiarly suited to the needs of a manufacturing town like Bradford; all of which would have been excluded by the selection of the "alternating" current, limited only to lighting.

While, again, with the "continuous" current, the use of the secondary battery (not possible with the "alternating" current) afforded, not merely a large reserve of power for use during the night, and at such times of the day, when it was also not desirable to run the engines and dynamos owing to the smallness of the demand, but also a most useful regulator acting upon the steadiness of the supply, and counteracting, or mitigating, any irregularity in the action of the steam-engines and other parts of the machinery.

The value of such a reserve as the storage battery, in case of any interruption or diminution in efficiency, through the sudden stoppage of any portion of the generating machinery, whether designedly or by accident, can hardly be appreciated.

The financial economy, due to the batteries, in the working of the generating station is very considerable, since the generating machinery can be completely stopped during many hours of the night and of the day, with a very marked saving in wages, coal, and other similar matters, as against the compulsorily uninterrupted running of the machinery, during the whole twenty-four hours, which is imperatively demanded on the "alternating" current system.

In the selection of "low pressure," for the distribution of the electric supply, as against "high pressure" (usually, though not necessarily, associated with the "alternating" current) it was felt that the primary duty of a municipal authority was to safeguard the public from as much danger as possible in a matter of this kind, even if such immunity should have to be purchased by the investment of a little more capital in the works (a fact which was extremely doubtful).

In the selection of the generating plant for a central station, in the centre of a large town, the important consideration, after efficiency, is probably that of compactness, and economy of floor space occupied, as ground is necessarily very valuable in such situation.

For this reason it was here determined, after very careful consideration, to adopt a steam-engine of the inverted vertical type, driving directly on the same shaft, a shunt-wound dynamo, both being placed upon the same bed-plate; an arrangement which allows of as much as 3 horse-power indicated per square foot of floor space being obtained.

Nor has this economy in floor space been obtained by a serious increase in the speed of the engines. Of the three engines first laid down, each of 150 horse-power indicated, two (Willans' single acting) have a maximum speed of 280 revolutions per minute, while the third (Marshall's double acting) does not exceed 180 revolutions. The rate of speed of horizontal engines for the same work would probably have been about 120 revolutions.

Owing to the difficulty of obtaining water for condensing purposes (at a rate of cost which would have been sufficiently reasonable to have effected any economy in fuel), it was decided to make the engines compound and non-condensing, with an initial steam pressure of 120 lbs. in the steam-chest.

It should be borne in mind that, with the Willans type of engine, triple expansion can at any time be readily adopted (if water for condensation should become available) by the interposition of a third cylinder between the steam-chest and the present high pressure cylinder.

The distinguishing feature of the demand for artificial illumination is the very great variation in the amount of that demand, which differs not merely according to the season of the year, but also during each twenty-four hours, which again may vary considerably according to the conditions of weather which may prevail on any individual day.

To endeavour to meet these varying demands, with due regard to economy, where steam is the motive power, it is absolutely necessary to have types of steam-engines which are of different producing capacities, so as to ensure that, according to the rate of the demand, a type of a size so proportioned be used,

such as may be doing a large per-centage of its full capacity, and therefore may be working under fairly economical conditions.

Bearing this in mind, there have been added later on (as the demand for the supply increased) two other types, namely, two engines of 80 horse-power indicated each, and two also each of 300 horse-power indicated.

Furthermore, secondary batteries (which may be looked upon as the equivalent of a 50 horse-power type of steam-engine), have also been erected.

With these four types (representing dynamos having each a maximum rate of output of 200, 300, 600, and of 1,200 ampères respectively), it will be seen that most of the very varying conditions of the demand for an electric supply can be met under fairly economical conditions.

In order to provide steam for the engines, it was decided to adopt the type known as the Lancashire boiler, which was considered as the most useful and the most economical, where steam in large quantities was regularly required.

There were first laid down three Lancashire mild-steel boilers, each of 7 feet diameter, and 28 feet long, working up to 140 lbs. pressure per square inch, and nominally of 180 horse-power. These have been working very satisfactorily for nearly three years.

A fourth similar boiler is now being added; and a Babcock and Wilcox, 120 horse-power nominal, has recently been fixed.

As adjuncts to the boilers, by previously increasing the temperature of the water with which they are fed, there were added later on a Feed-Water Heater, in order to utilise the heat of the waste steam after it had passed from the engines, and then a fuel economiser (Green's), to utilise the heat still remaining in the smoke before it escaped to the chimney.

To the above generating plant must be added the various electrical instruments and apparatus of many kinds (such as switch-boards, and regulating boards with their rheostats), intended for the regulation, measurement, and control of the supply of electricity before it was passed to the town.

All these various apparatus, though each individually partook of the general character implied by its name, were specially adapted to the circumstances of the locality, as well as to the magnitude of the currents to be carried. One distinguishing feature of their arrangement being that all connected with the +, or outgoing, mains were grouped along one side of the engine-room, while all those connected with the —, or return, mains were relegated to the other side of the room; an arrangement which, in the diminution of the chances of accident, has much to recommend it.

Of course, the standard instruments for comparing the measurements of other instruments, as well as those for the testing of meters, and many others, were placed apart in the testing room, as far removed as was practicable from the ever varying influence of the different masses of iron contained in the engine-room.

A further addition to the generating plant was made in the beginning of 1891, in the form of a secondary battery (Crompton-Howell), composed of a set of 70 67-plate cells (including some reserve ones for testing meters, &c.), each of 1,000 ampère-hours capacity, and with a normal rate of discharge of 200 ampères. This rate of discharge may, however, with this type of secondary battery, be considerably exceeded for a comparatively short period without injury to the cells.

In the working of a central station, where a very sudden call in the demand may arise most unexpectedly (through a fog coming on, or from some other cause), the importance of possessing such an elasticity in the maximum limit of the rate of discharge is very considerable; and it has here proved of great value on more than one occasion.

In the selection of a type of underground cable, including its protecting covering, which shall comply with the various requirements of an underground main in a town, the following points, amongst many, should be borne in mind (apart from its being an efficient and well protected conductor of electricity):—

1. It should be compact in form and take up little room.

2. It should readily adapt itself to the variations in direction as well as in level, which are constantly demanded from it in crowded thoroughfares by obstacles, such as gas and water mains; house services, cellars, lamp-posts, &c.

3. It should be readily accessible throughout its *entire* length, and not merely at certain points, for the connection of house services, as well as for side streets and for testing purposes.

All of the above points (and there are many other important ones) should be of much weight: but of them all, probably the last-named (readiness of accessibility throughout the whole of the cable) is of the most practical value in the various street operations, which are constantly occurring with a central station supply.

After careful consideration, a type of underground armoured cable (resembling, it was afterwards found, that in use in Berlin) was decided upon. It consists of a copper conductor, surrounded by an insulating layer, generally, but not always of a fibrous nature, with a seamless lead casing drawn over it by hydraulic pressure, and with a layer of well tarred jute or hemp round the lead. Then comes the mechanical protection in the form of two wrought iron or steel ribbons, each about 1½ inches wide, and wound spirally round the cable; the two ribbons breaking joint with each other. Outside is another layer of well tarred jute, braided and finished off. The total diameter of such a cable would be about 3 inches, even if the conductor occupied one-third of that amount.

This cable is laid direct in the ground, the excavation being again filled in with earth. After about 6 inches in depth have been filled in, a rough, ordinary deal board is laid down over the cable, to serve as a warning, when encountered by a pick or shovel, that an electric main is underneath.

It will be noticed that in this type of cable, the armouring or protection from external injury is carried directly upon the cable, and that at any point in its length this armouring can be cut and removed, in order to make a connection, without any detriment to the adjacent parts thereof.

All joints, with the above described armoured cables, whether upon the main itself, or for a street branch, or for a house service, are enclosed in a cast-iron case (mostly in an upper and lower half), which, after the joint is made, and the whole closed up, can be filled in from the outside, with a waterproof composition, so as to make the whole of the interior into a solid mass.

The mains are laid, almost without exception, along both sides of the streets under the pavement, thus avoiding breaking into the street itself (where the paving is generally expensive), in order to form the house connections, as would have to be done if a single main only had been laid.

Cast-iron street boxes of various kinds, to suit the several forms of connections, and placed under the pavement, complete the system of distribution, and afford ready facilities for movable attachments, whereby testing and other operations are much facilitated.

A site belonging to the Corporation, and containing about 1,200 square yards, and which is capable of considerable extension, was selected for the central station. Although in the middle of the town, it is outside of the compulsory area, selected to be first supplied with electricity.

On this ground the necessary buildings were erected. These were larger than was at first required, so as to admit of a considerable increase in the generating plant being placed within them. But these buildings themselves form only a part of a much larger building, which is now in course of construction—so rapid has been the development of the demand for the supply of electricity.

At the time of the commencement of the supply to the public, September 20, 1889, the following generating plant had been installed:—

Three Lancashire steel boilers, of 180 horse-power each; two Willans central valve steam-engines, each of 150 horse-power indicated, II. type; one Marshall double-acting steam-engine, also of 150 horse-power indicated; three Siemens shunt wound dynamos, each of 120 electrical horse-power (150 volts and 600 ampères), each dynamo being coupled to and driven direct by one of the above engines. Also, electrical boards and other apparatus necessary for controlling and regulating the supply to the town.

Since that time there have been added:—

In 1890, one Willans' engine of 300 horse-power indicated III. type, driving a Siemens' dynamo of 240 electrical horse-power (150 volts and 1,200 ampères); and in 1891, another similar Willans-Siemens set, and two sets each consisting of a Willans' engine of 80 horse-power indicated G G type, driving a Siemens' dynamo of 60 electrical horse-power (150 volts and 300 ampères), as well as a feed-water heater and a fuel economiser.

Early in 1891 there was erected the secondary battery of 70 Crompton-Howell cells of 1,000 ampère-hours capacity.

As regards the distributing system in the town: while at the commencement of the supply about nine miles of mains were laid in the streets, by the end of 1891 the total length had increased to 18 miles.

The motive power, as may be seen from the preceding statement, had about trebled, increasing from 450 indicated horse-power to 1,200 indicated horse-power; while the maximum rate of nightly output, from 1,400 ampères, at the end of 1889, had increased to a rate of 3,500 ampères at the end of 1891.

While the boilers and pipework had been constructed and laid down by Messrs. Holds-

worth and Son, of Bradford, and had given every satisfaction, the remainder of the work (exclusive of the secondary battery), but including the steam-engines, as well as the entire of the electrical work, both at the station and in the streets, had been supplied by Messrs. Siemens Bros. and Co., Limited; not merely of the original works, but also of the very considerable extensions that followed. Proving thereby, in the continued confidence which the Corporation reposed in them, and in Messrs. Willans' engines, how thoroughly and how efficiently the entire of the works had been carried out.

The secondary battery was supplied, and fixed by Messrs. Crompton and Co., Limited; and it is only fair to say, that so far it has given every satisfaction, and that it has proved itself a most valuable aid in the working of the supply of electricity.

The buildings, inclusive of their foundations, which are very heavy, owing to a portion of the site being upon the bed of a disused branch of the Leeds and Liverpool Canal, were built in a solid and efficient manner by Mr. Wm. Johnson, of Bradford; and they have proved, so far, well adapted to their work.

Cost of Working during 1890 and 1891.

The public distribution of the supply of electricity commenced on September 20th, 1889, since which date it has been carried on uninterruptedly. But as the working of the installation did not pass into the hands of the Corporation from those of the contractors, Messrs. Siemens, until about two months after, it will be convenient for the purposes of this paper to take the commencement of the regular working as from January 1st, 1890.

For the first few months the daily duration of the supply was from an hour before sunset to 11 p.m.; then, owing to a request for an extension of the hours of supply, it commenced at 10 a.m. and lasted till 11 p.m.

In February, 1891, the secondary battery already referred to having been fixed, the supply was made uninterrupted throughout the 24 hours; and it has continued so ever since.

It is well-known that the nature of the demand for the supply of light (that is, as to the time when it occurs, and as to the duration of such demands) depends very largely upon the character of the district. The one here supplied may be described as a "shop" district, with a few moderate-sized hotels in it, but without any private residences. Latterly, however, these characteristics have been somewhat modified, owing to extensions which have taken place into a neighbourhood where "warehouses" largely prevail. This term in the North of England is applied to a more ambitious building, both in its external appearance and the uses which it is put to, than a mere receptacle for goods and articles not in actual use, and does not include an office, nor possibly a resident keeper of the building.

A number of daily curves, some of which are shown in Figs. 3 to 7 (pp. 636-7), illustrate fairly the nature and extent of the lighting during that portion of each of the months selected, both in 1890, and on the corresponding day of 1891. Most of these curves are on a Saturday, which evening was, for some time, one of the heaviest in the week; but now is one of the smallest in demand (owing to the warehouses above mentioned not being on).

There is, even now, a certain amount of lighting during the day, due to basements of restaurants and of other buildings; this demand, of course, varies with the nature of the weather—if dark, foggy, or otherwise.

But there is another source of demand which is beginning to arise—that for motive power, for which a considerable field would appear to exist in Bradford. Where, dependent upon, and resulting from the larger manufactures of the town, are a number of much smaller industries, where mechanical power is needed, in quantity ranging from small dimensions up to that of several horse-power, a few of these electric motors have been fixed; some even up to twenty horse-power. They are used for hoists, lathes, and various other industrial purposes.

Then, again, electro-plating, a trade hitherto unknown in the town, has been started in one, if not more, establishments. I need not speak of the experiments which the Corporation are trying with the tramways, for the substitution of electricity for the steam-power at present in use; horse-power being quite inadmissible (except on one line), owing to the very steep inclines, which are constantly occurring. As steep as 1 in 15 (and even more so, in one or two cases); as well as to the great length of the inclines, averaging perhaps 1 in 30 to 40, for over a mile or more, without a counter-gradient to relieve them.

It is evident, therefore, that a very considerable demand will, before long, arise from the causes just enumerated, and that it will,

in great part, be a day demand, and also one which will arise in summer, just as well as in winter.

What a material advantage, financially, such a demand will be to the present working of the installation (successful, as it undoubtedly has been), a mere inspection of the lighting curves will show. Bearing in mind that this addition comes in to assist the weakest portion of the light curves—the daytime, and in summer too.

A mere glance at the daily curves for the latter part of 1891, will show what an important saving is effected each night by the use of the battery; instead of having to run the engines all night through, with so small a load as to be wholly unremunerative.

With respect to the working of the installation, much may be learnt from an examination of Fig. 1, which is a diagram showing the total receipts and the total expenditure of production, distribution, sale, &c. These, the running expenses, do not include interest on borrowed capital and sinking fund for the repayment of the capital, as required by the Local Government Board in the case of corporations.

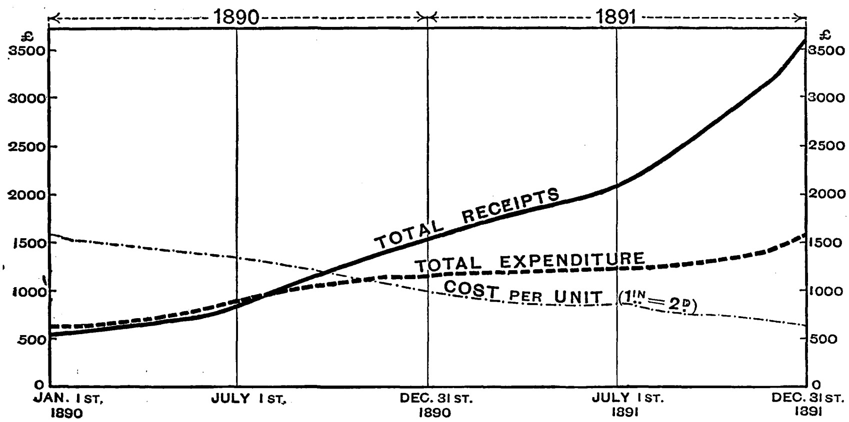

Fig. 1

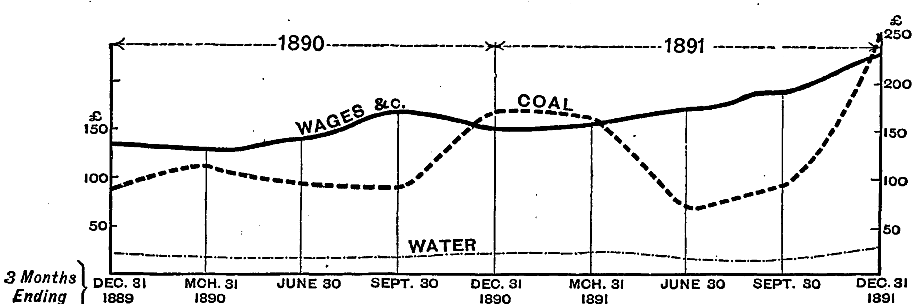

Fig. 2

The Table of the Profit and Loss account for 1890 and for 1891, which gives in detail the various items referred to in Fig. 1 is on p. 638. Also the Tables of the Capital Expenditure, and of the Net Revenue account for the same period.

An inspection of the wages, coal, and water consumption diagram (Fig. 2), as well as the rate of production per unit (excluding interest and sinking fund) will show in what a small ratio these items have increased; in proportion to the augmentation, both in the electrical output and in the receipts.

This is due, partly, to the fact that the services of the staff have been better utilised, latterly, than was possible at the commencement. To this result the use of the secondary battery has contributed largely; by allowing the services of the staff to be confined to twelve hours, on an average, mostly during the day

hours, instead of being scattered over the entire twenty-four (as would be the case with an "alternating" current station).

Again, as regards coal and water. Both of these items, the former more especially, have been much reduced of late by the use of the Feed-Water heater, and of the Fuel Economiser; these taking advantage of the heat (which would otherwise have been thrown away) contained in the waste steam, and in the smoke, after it has passed away from the boilers.

The economical value of each of these apparatus may be estimated from the following facts:—The average temperature of the feed-water to the boiler was when taken from the town supply, 55° Fahr.; this after passing through the feed-water heater was raised to 180°; and this again when passed through the fuel economiser, was raised to 280° before it entered the boilers.

By the word "coal" it must not be supposed that anything approaching to "picked steam-coal" is meant. The best of the coal used at Bradford would be well described by the word "nuts;" and to this is added, at the boiler, a very large proportion of "slack," or coal-dust of a poor description, and also of coke, of late. The best coal above used, the "nuts," costing from 8s. to 10s. per ton, according to the market value; while the "slack" costs about half that price.

It will be readily seen that engine trials,

intended to show a consumption of one and a half pounds of coal per indicated horse-power per hour, are not made with the above sort of stuff.

It should also be borne in mind that the figures given in the table are those of the "gross" coal bills, which include all the fuel required to keep the fires "banked" (during twelve out of the twenty-four hours), as well as all waste, and also engine trials, &c.

While on the question of coal, it may be urged that Bradford, and many other places in the vicinity of coal-fields, are in a better position than other towns which are situated farther away from those fields.

It may be of some interest to consider, what effect this difference in the cost of coal has upon the expenses, and consequently upon the selling price of the electrical energy, at each of such installations. For it may be assumed that the other matters, such as wages, water, oil, &c., remain pretty nearly the same in all large towns.

The author has had brought under his notice several places where these differences occur; in some cases engine coal costing about 25s. per ton, or about three times what it does in Bradford. After a careful consideration of such cases, the extra cost in the supply of coal would appear to be met, generally, by the increase of one penny per unit in the selling price.

This rough estimate is, moreover, borne out in the case of gas (the manufacture of which is affected in almost precisely the same way). It will be found that the price of gas per thousand cube feet, under similar circumstances, is increased by from 10d. to 1s., or a little over; and, taking roughly the illuminating power for domestic purposes of the electric unit as that of one hundred cubic feet of gas, this increase would correspond to the above rate.

In respect of water, however, the town of Bradford has a distinct advantage over many other places.

The Corporation supply (which alone is used at these works) is drawn from catchment mountain-basins, situate on a millstone-grit formation. It is of a peaty character, with a hardness of from two to four degrees, and it is admirably suited for use in boilers. It does not, of course, need the use of a "Water-softener," or of any other expedient, chemical or mechanical, to get rid of the excessive degree of hardness, or of other of the impurities which prove so detrimental to the well-being, as well as to the duration of boilers.

In conclusion, I have to request the Members of the Society of Arts (a Society which so faithfully and so thoroughly carries out its title as "The Society for the encouragement of arts, manufactures, and commerce") to join me in thanking

First, the Corporation of Bradford, not merely for their disinterested action in being the first to take up, and solve satisfactorily the question of the public supply of electricity by the local authority, but also for the way in which they have unstintingly and without reserve placed the results of their experience at the disposal of other Municipal Authorities, who may be desirous of carrying out, to the best of their ability, and for the benefit of their respective ratepayers, their duties, as regards a public supply of electricity.

Next, amongst the various members and officials of the Corporation, I must particularly refer to the Chairman of the Gas and Electricity Committee, Alderman Priestman, J.P., and to the worthy and much-respected Town Clerk, Mr. W. T. McGowen. Since it is not too much to say that, had it not been for the foresight and business qualities of those two gentlemen, coupled with their firmness and tact, in dealing with the many difficulties which, naturally, beset a young and novel undertaking of this kind, it is extremely doubtful whether there would have been any public supply of electricity in Bradford at all, even at the present time. To myself, personally, their kindly support and assistance, ever readily placed at my disposal, has been evinced on so many occasions, that I am unable, adequately, to do anything more than simply thank them.

I must also advert to Mr. S. W. Baynes, the present resident manager of the installation, and to the ready co-operation which he has always afforded me, not merely in his present position, but also previously, while acting as clerk of the works during the construction of the works described in the paper. To his indefatigable energy, and good management in the working of the installation, is due, very largely, the commercial success which has attended it.

My thanks are also due to the several contractors who have been connected with me in carrying out the works. But, as by far the largest part of those works, as well as the heaviest responsibility, fell to Messrs. Siemens Bros. & Co., so must I also mention Mr. A. Siemens, of that firm, and his hearty co-operation and assistance ·er afforded when-

ever any peculiar or novel question presented itself for solution.

To my various brother officials of the Corporation of Bradford, as well as to others outside thereof, I would give my best thanks for the kindness and courtesy which I have received at their hands.

DISCUSSION.

The CHAIRMAN said there was one omission in the paper which he wished Mr. Shoolbred would supply, viz:—the number of lamps fixed.

Mr. SCHOOLBRED said he always objected to put the information in that form, which he considered most delusive. The number of lamps fixed did not tell you the number burned, any more than the number of gas-burners told how much gas was consumed; 3,500 ampères was the maximum output, and if 16-candle lamps were used there would be probably about 7,200 burning at one time. How many were fixed he could not say — perhaps double that number, but the Corporation had no power to enter the houses and see what the fittings were. The lamps were of all kinds from 8-candles upwards, and there were some arc lamps. Possibly Mr. Baynes might have some data on the subject.

Mr. BAYNES said there were at present 19,000 lamps on the circuit, all reckoned as 8-candle-power lamps; and the arc lamps were counted in the same way.

Mr. R. E. CROMPTON said he was much pleased to find that what he had so long strenuously advocated—the use of accumulators, coupled in parallel with a number of steam dynamos of various styles—had proved so successful in this case, and that in such a crucial test as that shown in the last diagram, where the largest engine was suddenly thrown out of use, the accumulators had prevented a breakdown. Several similar instances had occurred in London, one in particular where the safety-valves of the boiler lifted, and the boiler was rendered useless for a considerable time. In that case there was a much greater drop in the E.M.F. than was shown in the diagram, but still the supply was maintained. In several large stations where accumulators were used there had been no interruption of the supply for several years. He was also glad to have Mr. Shoolbred's testimony to the fact that this method was not excessively costly, but on the contrary, economical. The diagrams showed very clearly what a fluctuating load was thrown on the engine, and what a different task the electric lighting engineer had to perform to that of driving ordinary machinery in a factory, or in a steamship. They were often told that accumulators were not economical, and it was only since he read a paper last year at the Institution of Engneers that people began to recognise the conditions under which they worked, and how widely they differed from those to which they had been compared. Though many engineers to private companies had volunteered similar information their testimony was often looked on with suspicion, but this was so entirely impartial and unbiassed that it would be of great use in combatting the absurd pretentions sometimes brought forward by the advocates of special systems. Mr. Shoolbred would add greatly to the value of his paper if he could give more detailed information as to the comparative efficiency of his boilers. In London, on account of the restricted space, they generally used other systems, and were often told that economy could be effected by the use of Lancashire boilers, and he should be glad to know, therefore, what the evaporative power actually was per heat unit. He did not think Mr. Shoolbred had done much better with his boilers than they did in London, allowing for the difference in the cost of fuel.

Mr. ALEXANDER SIEMENS, after thanking Mr. Shoolbred for the kind way in which he had spoken of his firm, said he could not agree with him as to the use of accumulators. The diagram showed that when a sudden stoppage occurred the battery-power was of great use, which he did not deny, but he thought batteries would only be useful in what might be called toy stations. If the demand required the addition of a battery giving 500 ampères, it only showed that the station was not big enough. If the same sort of thing occurred in a full-sized station, there would be a larger number of dynamos, and when one failed the others would take up the work, without causing even the trifling drop in the potential as had taken place there. He was very glad to see this success of a station worked by a local authority, because he thought gas, water, electric light and such things could be best supplied to the consumers by public authorities, so that any profit derived should go to the whole community. The diagram showed how quickly such an undertaking might be rendered profitable. The shape of the curves was startling enough, but it simply showed that, so far, there had been merely a lighting business done: the curve would flatten out when motors came more into use. There was another mode of overcoming the difficulty of a varying load, but, as it was about to be patented, he would say nothing about it, except that he thought it would astonish the accumulator people.

Mr. WILLANS congratulated Mr. Shoolbred and the Corporation of Bradford on the steady progress made since the commencement. It was very satisfactory to him to find that the first corporation to take up the subject had recognised the importance of adopting direct driving, especially as it was a town where all the machinery was driven by belts or ropes from large engines revolving slowly. Millowners and people accustomed to machinery hardly understood the conditions which obtained in a central electric light station. Last week he had occasion

to start a cotton mill engine of about 659h.p., and it was really child's play to what an electric light engineer had to do, it was so simple in comparison. If this station had been fitted upon the mill plan, they would have put up a 500 or 600h.p. engine, and if anything had happened to it all the lights would have gone out, unless accumulators were employed, and even they could not have carried on the whole thing; and the engine for a great part of its time would have been doing hardly anything in proportion to the coal it consumed. It was only by dividing the total power required into units of reasonable size, that economy could be effected. Even then the time during which the engines were at work was so short, that they could never hope to compete in economy with engines driving steamships or factory machinery.

Mr. BAILEY regretted the absence of any information as to the number of lamps connected, or the average time they burned during the year; and in order to give that, it would be necessary to analyse the use of each lamp. Nothing would be more useful than to know what was the most remunerative class of customer. It was clear from the diagram that if 3,200 ampéres went out on a certain day that would represent about 9,600 8 candle power lamps, and therefore if there were 9,000 lamps connected, the lamp factor was about 50 per cent. If that were so he congratulated the Corporation of Bradford on a result which was rarely attained, the average in London for house and shop lighting being 33 per cent. This point had several bearings, it might bring down the revenue per lamp, but on the other hand, it introduced a term which might be rather dangerous on very dark or foggy days when a greater proportion of lamps might be on. The whole object of keeping a strict record of lamp connections was to look out for that danger signal, and not go beyond the point where it was safe to connect more lamps without increasing the plant. It would always be very useful if a map of the district could be added to the paper. It was desirable that a corporation undertaking the supply of electricity should treat all ratepayers on the same footing. It was clear the whole town could not be supplied from this station, and therefore he should like to know, not only the number of lamps connected per yard run, but what area was left unsupplied by the existing plant, and if it would be possible, by increasing the present plant, as arranged, to supply the whole of those who might be expected to require the electric light.

Mr. RECKENZAUN asked for details as to the cost of installation, engines, boilers, dynamos, &c.

Mr. BAYNES was happy to be able to endorse all that Mr. Shoolbred had said concerning the Town Clerk and Chairman. In response to Mr. Crompton's inquiries, he might say that Mr. Shoolbred had rather over than underestimated the cost of coal; the average cost being rather over 6s., including a large amount of slack. The water evaporated was 6·684 lbs. per lb. of coal at a working pressure of 140 lbs., or reduced for feed water at 212° F., and evaporation at atmosphere pressure, 7·59. The coal was of very low calorific value, but, at the price paid, was probably cheaper than Welsh coal. The lamp hours could be arrived at from the following figures: 20 units were consumed per annum for a 35 Watt lamp, and the apparent revenue was 9s. 7d., taking the average cost of electricity at 5½d. per unit. The total leakage between the mains was ·02 ampères=500 ohms insulation resistance, including mains, switch boards, dynamos, and a large number of the lamps on the circuit.

Mr. MCGOWEN (Town Clerk of Bradford) said he did not pretend to any intimate acquaintance with the scientific side of the question, but he thought it was a bold venture on the part of the Corporation to go into the matter in the way they did. They had every confidence in the skill and ability of Mr. Shoolbred, but still it was thought necessary on all the most important points to obtain the advice of the highest authorities, and, though there were some differences of opinion, in the end, he believed, even those who held the strongest views in opposition to the methods proposed and carried out had been convinced that they were the right ones. It was very satisfactory to him to find such a general consensus of opinion, by gentlemen competent to speak, in favour of the means adopted for carrying out this work. One point which led to considerable controversy was the size and character of the engines to be employed—whether they should have one or two of enormous power, or a larger number of moderate size, which could be used as occasion required; and it would be very gratifying to the Corporation to learn that the course adopted had been approved.

Sir THOMAS BAZLEY, Bart., asked if the accumulators stood their work well, or required much repair.

MR. GARCKE said the accounts of local authorities were sometimes looked on with suspicion because it was supposed that any particular department might be favoured to some extent at the expense of another if so desired, and with a view to disarming that kind of criticism it would be well if further details could be given of the profit and loss account. The only item of standing charges was wages and salaries £506 for the half-year, which was a very low figure; he did not see any items for rent of offices, clerks, insurance, collection, bad debts, or any other items of that description. The total came out very low, and if there were any other matters which ought to be charged they would not prejudicially affect the result. The chief lesson to be learned from the paper was that local authorities could establish and work these stations very economically, and to the advantage of everybody. This point had already been mentioned, but deserved emphasizing, especially as the cost per lamp was very low, and compared

favourably with central stations established by private companies. The cost of coal was low for the special reasons referred to, but all the other expenses also were very low. If Mr. Shoolbred could conveniently tell them the total number of units generated it would afford, in comparison with the units sold, a very clear view of the efficiency of the system.

Mr. ALBRIGHT asked if the 2·47d. per unit included the cost of distribution as well as the engineering expenses, and if the depreciation of the mains was included in "repairs and miscellaneous." That had an important bearing on the question raised by Mr. Bailey as to the size and nature of the district. He feared some people would take up these figures, and jump to the conclusion that the difference between the 2.47d. and the price at which it was supplied was all clear profit. Mr. Baynes said the average earning per lamp was 9s. 7d., and the total number of lamps fixed 19,000; but if the total revenue were divided by 9s. 7d., it gave about 7,000 lamps fixed. Of course, the number of lamps might have been doubled or more since that account was prepared.

Mr. BAYNES said that was the explanation. There were 19,000 lamps now, reckoning the present applications for lights, &c., but at the date when the balance-sheet was made out they were much fewer.

Mr. OLIVER WILLIAMS asked for further information as to the probable deterioration of the plant and the mains, and particularly in the batteries.

Mr. SHOOLBRED, in reply, said it was very difficult to give exact details as to the evaporative power of boilers, when they were once started in regular work. Several trials were made in early days as to the quantity of coal consumed and water evaporated, but when once the station was fairly in work, it was almost impossible to go on with such inquiries. He thought it very doubtful whether the Babcock and Wilcox boiler, taking it all round, came up to the Lancashire, though, in certain circumstances where steam was suddenly required, it might be more convenient. With reference to the remarks of Mr. Bailey and others about lamps, he would point out that there was a material difference between the position of a corporation and that of a company; a corporation had nothing to do with the lamps inside the houses, and did not know what they cost or how long they lasted; whereas companies frequently derived a considerable income from lamps and fittings. The number of lamps was a delusive mode of gauging the output of a station, which should be reckoned in ampères, at a certain pressure. With regard to the invidious distinction involved in selecting a certain portion of the town, some complaints were made about it in early days, but the ratepayers' fears and jealousies were allayed when it was found that the compulsory area was selected by the Board of Trade in the first instance, and the question of extension was entirely in the hands of the ratepayers themselves. When a sufficient number came forward and asked for a supply to guarantee a certain revenue, the corporation could make the extension by a resolution of their own body. They had to begin somewhere, and in order to do it at all under commercial conditions, a small number of streets were selected by the Board of Trade, so as to relieve the local authority of the onus of such selection. He had no hesitation in saying that this system of low pressure selected could be carried out, not only throughout the town of Bradford, which was, roughly speaking, an oval about five miles by three miles in extent. But it might be readily extended to other districts in the vicinity. For, he thought, the Corporation intended supplying neighbouring districts, though outside the borough, with electricity in the same way as they did with water. Of course there would have to be proper intermediary stations, which would be gradually increased. There would be no necessity for introducing what was termed high pressure. In some of the feeding mains it might be necessary to go beyond the 300 volts, which was the nominal limit of low pressure, but not to anything like 2,000 volts, which was ordinarily used with the alternating current system. The question Mr. Reckenzaun asked was, to a certain extent, answered in the paper, and he could not, from memory, give the full details. The total cost of the first installation was £18,456, which included engines of 450 horse-power and dynamos and street distributing service, to correspond; but at that time there were no batteries. They cost, when finished, with their connections, about £2,000; and it was about the best investment that had been made, the saving thereby effected being very great. With regard to their working and maintenance, it was very satisfactory so far; he heard very little ot buckled plates or sulphating; but that was no doubt largely due to careful management. It could be seen by the diagrams that they were charged gradually and regularly, and discharged in the same way; and that really conduced to keeping them clean and in good order; the cost of maintenance was, in fact, a mere trifle. The figures given in the Table included production, distribution, cost of sale, &c; there were no clerks or collectors to charge for as extra. Possibly a few items might come in under the head of "miscellaneous;" but every thing connected with the business was included in the Table. Later on, a larger staff might be required for collection, but that would be similarly included. A careful distinction was made between expenditure on capital account—such as laying down new mains—and what was fairly charged to revenue. But he should point out, as was distinctly stated in the paper that these running expenses did not include interes on capital, or sinking fund for its redemption, which formed a large proportion of the expenses which a corporation was bound to meet; and, of course, the

proportion of these expenses was to be added to the cost of the 2 47d. per unit (the cost of production in the latter part of 1891), as named in the Table. He was glad to find that the mode of dealing with the question of the engines to be employed had met with approval. It was of course desirable that these engines should be worked, as far as possible, under the most favourable conditions, which meant under as near a full load as possible; and that could only be attained by having several sizes of steam-engines, which should correspond somewhat to the variation in the daily demands of the different seasons of the year.

The CHAIRMAN, in proposing a vote of thanks to Mr. Shoolbred, said he felt very strongly that the Coporation who failed to introduce the electric light to their ratepayers were neglecting a very serious duty. Not only on economical but on sanitary grounds they ought to take up the matter, and this paper showed very forcibly that financial success would attend the operation. Bradford was the first Corporation which had had the temerity to attack this question, and they were all delighted to find that their courage had met with its reward. He had been surprised at the hesitation shown by Mr. Shoolbred in answering the question he put as to the number of lamps, which was the very pith of the whole question. In regulating domestic expenditure or establishing a business you required to know how many mouths you had to feed or what demand you had to meet, and if you wanted to supply electricity you wanted to know how many lamps you would have to supply with current. When you knew how many lamps were to be fixed all the rest followed as matter of course. Experience showed that only a certain percentage of those fixed required to be supplied with current at the same time, and when you knew the current you knew the power required, and from this could calculate the engines, dynamos, and plant necessary at the central station. Another reason for asking the question was because he wanted to have some conception how far electricity was interfering with gas in Bradford. He was interested in this as a gas shareholder, but up to the present moment he had never felt any anxiety about his gas property. Electricity was not interfering with gas in any way, and he did not think it was likely to do so. The users of gas wanted to know what was the comparative cost of electric light. The average price of gas in England was about 3s. per thousand feet, and the average cost of a gas lamp was 9s. per annum. If at Bradford the average price paid per electric lamp was 9s. 7d. it showed there was not much difference between the cost of electricity and gas, and they could tell people with confidence that the cost would not be much more. But when a man introduced electric lighting he generally had gas fixtures, pipes and so forth, and he began to think how he could make use of them and apply the gas to other purposes, and so he applied it to heating, cooking, and power. Wherever electric lighting was introduced it not only did not diminish the supply of gas, but increased it. He must also enter his protest against the question of the relative advantages of continuous and alternating current being disposed of so summarily as was done in this paper, and the same with regard to high pressure and low pressure. Engineers were called upon to apply this great force of nature, and to do it in such a way as to incur the least possible expenditure both of capital and revenue. When an engineer went to a particular district he had to take everything into consideration, and if he found he could more cheaply apply continuous currents he would do so, but if he found the alternating current was more advantageous he would use that. He was using much more the continuous current than the alternating on account of the special circumstances. There were two central stations in London connected with the Post-office, each as large as that of Bradford, one in the City, supplying sufficient current for 10,000 lamps, the other, nearly completed, and of the same size, at Mount-pleasant. In each of those localities they had to supply a small compact district; but when they went to large scattered districts like Manchester, Bristol or Liverpool, he could not conceive any one introducing anything else but a good, well worked out high pressure system. Mr. Shoolbred had said that the alternating current could not be utilised for supplying motive-power, or for electrical deposition or storage; but though this might have been true once it was not true now. The great lesson they learned at the Frankfort Exhibition was that alternating currents were more economical for motive-power than continuous, and you could charge batteries and deposit metals equally well with such currents; it only required the introduction of a transformer to convert the alternating current into a continuous form. One other question was that of using secondary batteries as a stand by to provide against a breakdown. No one in a toy station, as Mr. Siemens called it, would dream of constructing his installation without putting in a battery, but it was simply a question of £ s. d. Mr. Shoolbred had shown that the one he used was equivalent to an additional 50 horse-power engine. On the one hand must be put the depreciation in the battery, the attendance required to keep it in order, and so on; and on the other, the cost of maintaining and working a 50 horse-power engine. If they were about equal, well and good. You must choose whichever was most convenient, but you would come to a point sooner or later where the cost of maintaining a small engine and dynamo would be much less than that of maintaining the battery, and then the battery must go, and the engine would have to do the work. They were much indebted, not only to Mr. Shoolbred, but to the authorities of Bradford for having so cheerfully, not only shown the details of their central station to all who were interested, but for giving and allowing their consulting

engineer to give so much detailed information. The pluck and liberality shown by the Corporation had done more probably to assist the progress of electric lighting than anything else could have done, and he must therefore ask the meeting to include the Corporation of Bradford in the vote of thanks.

The vote of thanks was carried unanimously, and the meeting adjourned.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at Eight o'clock :—

MAY 11.—G. L. ADDENBROOKE, "Uses and Applications of Aluminium."

MAY 18.—Captain W. de W. ABNEY, C.B., F.R.S., "Colour Blindness." R. BRUDENELL CARTER, F.R.C.S., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m. :—

MAY 19. — JERVOISE ATHELSTANE BAINES, I.C.S., Chief Census Commissioner for India, "The Indian Census of 1891." Sir CHARLES BERNARD, K.C.S.I., will preside.

FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at Eight o'clock :—

MAY 24.—Colonel HOWARD VINCENT, C.B., M.P., "The Extension of Colonial Trade."

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock :—

MAY 17.—WILLIAM SIMPSON, R.I., "Mud as a Material for Architecture in Persia and the East." General ROBERT MACLAGAN will preside.

MAY 31.—WILLIAM DE MORGAN, "Lustre Ware."

CANTOR LECTURES.

Monday evenings, at Eight o'clock :—

Professor PERCY F. FRANKLAND, Ph.D., B.Sc., F.R.S., "Recent Bacteriological and Chemical Research in connection with the Fermentation Industries." Four Lectures.

LECTURE II.—MAY 9.—Culture media—Methods of sterilisation—Pure cultivation—Special methods for the cultivation of particular micro-organisms.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 9... SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Dr. Percy F. Frankland, "Recent Bacteriological and Chemical Research in connection with the Fermentation Industries." (Lecture II.)
North-East Coast Institute of Engineers and Shipbuilders, 8, Nicholas-buildings, Newcastle-on-Tyne, 7½ p.m.
Surveyors, 12, Great George-street, S.W., 8 p.m. Professor G. E. S. Boulger, "The Scientific Study of Timber."
Geographical, University of London, Burlington-gardens, W., 8½ p.m.

TUESDAY, MAY 10...Society of Architects, St. James's-hall, Piccadilly, W., 8 p.m. Rev. J. E. Field, "Monumental Brasses."
Royal Institution, Albemarle-street, W., 3 p.m. Mr. F. E. Ives, "Photography in the Colours of Nature." (Lecture I.)
Medical and Chirurgical, 20, Hanover-sq., W., 8½ p.m.
Civil Engineers, 25, Great George street, S.W., 8 p.m. Mr. A. P. Trotter, "The Distribution and Measurement of Illumination."
Photographic, 5A, Pall-mall East, S.W., 8 p.m.
Anthropological, 3, Hanover-square, W., 8½ p.m. Mrs. Bishop (Miss Bird), "The Ainos of Japan."
Colonial Institute, Whitehall Rooms, Northumberland-avenue, W.C., 8 p.m.

WEDNESDAY, MAY 11... SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. G. L. Addenbrooke, "Uses and Applications of Aluminium."
Geological, Burlington-house, W., 8 p.m. 1. Prof. T. G. Bonney, "The so-called Gneiss of Carboniferous Age at Guttannen (Canton Berne, Switzerland)." 2. Prof. Grenville and Messrs. A. J. Cole and G. W. Butler, "The Lithophyses in the Obsidian of the Rocche Rosse Lipari."
United Service Institution, Whitehall-yard, S.W., 3 p.m. Mr. W. Laird Clowes, "The Place and Use of Torpedo Boats in War."
Royal Literary Fund, 7, Adelphi-terrace, W.C., 3 p.m.

THURSDAY, MAY 12...Royal, Burlington-house, W., 4½ p.m.
Antiquaries, Burlington-house, W., 8½ p.m.
Society for the Encouragement of Fine Arts, 8½ p.m. Third Conversazione at the Galleries of the Royal Institute of Painters in Water Colours, Piccadilly, W.
Royal Institution, Albemarle-street, W., 3 p.m. Professor Dewar, "The Chemistry of Gases." (Lecture III.)
Electrical Engineers, 25, Great George-street, S.W., 8 p.m. 1. Discussion on Mr. A. P. Trotter's paper, "Notes on the Light of the Electric Arc." 2. Dr. J. H. Gladstone, "The Cause of the Changes of Electro-motive Force in Secondary Batteries."
Mathematical, 22, Albemarle-street, W., 8 p.m.

FRIDAY, MAY 13...United Service Club, Whitehall-yard, S.W., 3 p.m. Captain J. D. Fullerton, "Modern Aërial Navigation."
Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting, 9 p.m. Dr. W. Huggins, "The New Star in Auriga."
Institute of Architecture, Science and Art, Dundee, 8 p.m.
Astronomical, Burlington-house, W., 8 p.m.
Philological, University College, W.C., 8 p.m.
Clinical, 20, Hanover-square, W., 8½ p.m.
Physical, Science Schools, South Kensington, S.W., 5 p.m. 1. Mr. Richard Inwards, "An Instrument for drawing Parabolas." 2. Mr. F. H. Nalder, "Some Electrical Instruments." 3. Messrs. E. Edser and H. Stansfield, "An Instrument for measuring Magnetic Fields."

SATURDAY, MAY 14...Royal Institution, Albemarle-street, W., 3 p.m. Mr. E. Dannreuther, "J. S. Bach's Chamber Music" (with illustrations). (Lecture III.)
Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.

The Telegraphic Address of the Society of Arts, and of the Royal Commission for the Chicago Exhibition, is "Praxiteles, London."

Journal of the Society of Arts.

No. 2,060. Vol. XL.

FRIDAY, MAY 13, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

GENERAL MEETING.

Temporary Alteration of Bye-laws.

The Council hereby convene a General Meeting of the members to be held at the Society's House, in the Adelphi, on Wednesday, the 18th May, 1892, at 4 o'clock in the afternoon, for the purpose of considering, and if thought desirable of passing, the following resolutions:—

1. That in accordance with the proposal from the Council, the Bye-laws be altered and varied in such manner that the Council shall be empowered, during the years 1892 and 1893, to appoint not more than six members to be Vice-Presidents or other Members of the Council in addition to those appointed under Bye-laws 79 and 84, and that the Council be empowered to determine the period or respective periods that members so appointed shall continue in office, not being later than the end of the Session commencing 1893, and that all Bye-laws which are inconsistent with such appointment and determination be suspended or varied.
2. That Bye-laws 8, 9, and 10 be suspended during the Sessions 1892-3 and 1893-4.

By Order of the Council,

Henry Trueman Wood,
Secretary.

2nd May, 1892.

Bye-Laws 8, 9, *and* 10.

8. The Chairman of the Council shall be chosen from those Members of the Council who are of one year's standing at least.

9. The Chairman of the Council, after two years' service, shall not be re-eligible to the office for at least one year.

10. The Chairman of the Council shall deliver an address to the Society at its Ordinary Meeting after his election.

CANTOR LECTURES.

The second lecture of the course on "Recent Bacteriological and Chemical Research in connection with the Fermentative Industries," was delivered by Professor Percy F. Frankland, Ph.D., F.R.S., on Monday evening, 9th inst.

The lectures will be published in the *Journal* during the autumn recess.

Chicago Exhibition, 1893.

INDIA COMMITTEE.

A meeting of the India Committee was held on Tuesday, 10th inst. Present: Major-General Sir Owen Tudor Burne, K.C.S.I., C.I.E. (Chairman of the Committee), Sir Frank Forbes Adam, C.I.E., Lionel Robert Ashburner, C.S.I., M. M. Bhownaggree, C.I.E., Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M D., C. Purdon Clarke, C.I.E., William Digby, C.I.E., Sir Joseph Fayrer, K.C.S.I., M.D., LL.D., F.R.S., Colonel C. L. O. Fitzgerald, C.B., W. S. Halsey, Lieut.-General J. Michael, C.S.I., Dadabhai Naoroji, Charles Pontifex, Vincent J. Robinson, C.I.E., Alexander Rogers, Thomas H. Thornton, C.S.I., D.C.L., Stephen Wheeler, Sir Alexander Wilson, Sir Henry Trueman Wood, M.A., Secretary of the Royal Commission, and S. Digby, Secretary to the Committee.

AMERICAN PATENTS.

The following Act has been passed by the United States Congress:—

"An Act to protect foreign exhibitors at the World's Columbian Exposition from prosecution for exhibiting wares protected by American Patents and Trade marks."

"*Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled.* That no citizen of any other country shall be held liable for the infringement of any patent granted by the United States, or of any trade-mark or label registered in the United States,

where the Act complained of is or shall be performed in connection with the exhibition of any article or thing at the World's Columbian Exposition at Chicago.—Approved April 6, 1892."

APPLICATIONS FOR SPACE.

Intending exhibitors are reminded that applications can only be received up to Saturday, 21st May. Any applications received after that date will be filed, in case of any space becoming hereafter available, but will not be included in the allotment.

All applications must be made upon forms to be obtained from the Secretary of the Commission at their offices, Society of Arts, John-street, Adelphi, London, W.C. They must be sent in, properly filled up, and addressed to the Secretary, as above.

Proceedings of the Society.

INDIAN SECTION.

Thursday, April 28, 1892; SAMUEL SMITH, M.P., in the chair.

The paper read was—

THE REORGANISATION OF AGRICULTURAL CREDIT IN INDIA.

By SIR WILLIAM WEDDERBURN, BART.

In India, the one great industry is agriculture. There are very few large towns. And of the 222,000,000 of British subjects some 80 per cent. are more or less directly dependent upon agriculture; the backbone of this great agricultural class being the ryots, or peasant cultivators, who, throughout the whole peninsula, live grouped together in village communities, somewhat similar to English rural parishes. Such being the nature of the population, the most vital of Indian questions is the condition of the Indian ryot. Upon his ability to pay taxes depends the financial stability of the empire, and upon his contentment depends its political safety. If, therefore, we regard our Indian empire from a selfish point of view, the ryot comes first in importance. Also he comes first from the point of view of our responsibility and duty. For if there is death and disaster in India from war, pestilence, or famine, the ryot is the principal sufferer. And in his sufferings he has no one to look to but us. We retain all the power in our own hands; and therefore upon us rests the whole burden of the responsibility.

I repeat, the most vital question in India is the condition of the India ryot. And unfortunately his condition, for the most part, is very bad. He and his family subsist with difficulty upon the poorest and most scanty fare. A well-known official estimate has declared that one-fifth of the population, that is some 40,000,000 of persons, are chronicly in a state of semi-starvation, passing through life without ever having their hunger satisfied. Possessing no savings of money or food, and living thus on the verge of subsistence, the Indian peasantry are therefore helpless in times of scarcity. And one bad season, one failure of the periodical rains, is sufficient to produce widespread famine, and to cause the death of hundreds of thousands, and even millions, of these unfortunate people. In the last great famine in Madras and Bombay 5,000,000 of persons were officially reported to have died of starvation: that is, a mass of human beings exceeding the whole population of Ireland, mostly frugal industrious peasants, men, women and children, for whose welfare we are directly responsible, perished within the space of little more than a year from the slow pangs of hunger.

Now my object in addressing you to-day is to say that I am firmly convinced that this suffering is altogether unnecessary and preventible. These wholesale disasters are simply and solely due to the extreme and chronic poverty of the people. Famine would practically be prevented if the ryot were in a position to tide over even one bad season. And there is no reason whatever why, with his industry, thrift, and skill, he should not attain that position. The ryot's difficulty is a financial one. Give him but reasonable fair play in that respect, and he would make himself not only safe from famine, but comfortable and even prosperous. The poet speaks of the "Wealth of Ind." The phrase seems a mockery looking to the present condition of the country. But none the less India possesses the conditions of almost boundless agricultural wealth. In her vast domain she has climates suited to every known product. She has a fertile soil and an unfailing sun, with abundant labour, skilful and cheap. All that is wanted is capital. Give the ryot that, so that he may be able to command a proper supply of water and manure, and he will produce in perfection every valuable crop known to cultivation. At present the ryot, as a

class, has no capital. He has less than none. For he is deeply, and often hopelessly, in debt. Through this burden of debt his independence and enterprise have been crushed, and he has become the bond-slave of the village money-lender. What the ryot wants is to be delivered from this bondage, and to be supplied with sufficient capital at reasonable rates. He may then be left alone, for he is by nature sturdy and industrious. He will at once proceed to dig a well on his ancestral land, he will supply himself with water and manure, and in the end will turn the whole of India into a garden. I have myself seen such a process going on upon a small scale under my own eyes when, in the neighbourhood of Poona, water and manure were made available. The same land which, when dependent on the natural rainfall, yielded a precarious crop of millet not worth ten shillings an acre, produced, when irrigated and manured, an assured crop of sugar-cane which sold uncut upon the ground for £25 an acre. As I have already said, the ryot's difficulties are of a financial kind. Help him in that matter, and he will do the rest, and soon place himself and his dependents beyond the reach of famine.

It is not as though there were any lack of available capital in the country. From the returns of the three Presidency banks I observe that last year some 14 crores (that is 14,000,000 of tens of rupees) were locked up in those institutions. In Bombay there was such a glut of capital that the Presidency bank had 5 crores of deposits which it did not know how to use, so that it was driven to refuse municipal and other deposits except as current accounts which bear no interest. In the Post-office Savings' Banks at Bombay, some 2 crores were locked up, while private banks could get any amount of deposits at 4 per cent. Such is the plethora of money nigh at hand in India, not to speak of the accumulated capital in Europe seeking investment, while the ryot is perishing for want of it. It is as though on the one hand we had rich but thirsty soil: on the other hand vast stores of fertilising water. What we want is to construct good channels of communication, so that the water may be brought upon the land, to the great benefit of all parties concerned. The question is, how is this to be done? How can agricultural credit be best organised and established on a firm and scientific basis? Fortunately we have for our guidance the example and experience of credit institutions which have been successfully worked elsewhere, especially on the Continent of Europe. There it has been found that agricultural banks have been the salvation of the peasant cultivator. And I propose now to lay before you a brief statement of facts showing the steps taken to adapt the same system to the special needs of the Indian ryot. I will relate the circumstances under which a scheme was formed to establish an experimental bank for this purpose in the Bombay Presidency; and I will show how our project seemed on the eve of success; but how at the last it was defeated and upset. In this matter I have a complaint of a grave kind to make against the authorities of the India-office. The scheme was one which they were bound to support. Nay, more; they ought themselves long ago to have initiated similar measures for the ryots' relief and safety. Yet instead of giving the movement every encouragement, they alone threw obstacles in its way. As I will show presently, all those locally interested welcomed the scheme gladly; public opinion in India and in England was in its favour; the Viceroy in Council strongly recommended the experiment being tried. Everything seemed favourable. All that was needed was the formal sanction of the India-office. This was refused; and the whole scheme was wrecked. To make the facts clear I will divide what I have to say under three headings, showing (1) the position of the ryot and the cause of his financial distress, (2) the nature of the proposed remedy, and (3) the attempt to apply this remedy, and how the attempt was defeated.

(1) *The financial misfortunes of the ryot.*—As our attempt to establish an Agricultural Bank was made in the Dekkhan districts of the Bombay Presidency, and as the Dekkhan ryot is in most respects typical of the peasant cultivator throughout India, I will briefly describe his economic position, showing his customary connection with the village money-lender, and some of the principal causes which have led to his present ruined condition. We shall then see that the ryot's original relations to the money-lender were highly beneficial to both parties; that these relations have become disorganised, mainly through the introduction of unsuitable English laws; and that what is now wanted is to restore the old friendly relations between the parties upon a scientific and well organized basis. In the Dekkhan, then, the old-established connection between the ryot and the village money-lender is the following: the ryot owns the land and

the cattle, and supplies the labour by himself and family. On the other hand the money-lender, who is also a general dealer, maintains the whole party until the harvest becomes available, and provides cash to pay the Government assessment, and for incidental expenses, as when a plough bullock dies, or when a marriage has to be celebrated. He also generally supplies the seed corn. The crop thus obtained is shared between them at harvest time; and this arrangement is fair and equitable, one share of the crop going to the ryot as the reward of his labour, and one share to the money lender as the profit on his capital. There existed thus a sort of *métayer* partnership between them, neither being able to get on without the other. As Sir John Strachey has put it, "Money-lenders are obviously as necessary to the Indian agriculturist as the seed which he sows, or as the rain which falls from heaven to water his fields." In a bad year, if the crop failed, the ryot asked for time to pay his debt: "Have patience with me and I will pay thee all." As in the parable the creditor was then expected to show forbearance, and as a fact he rarely failed to do so. And this natural leniency, arising from the friendly relations of the parties, was increased by the fact that under native Governments, and in the earlier days of British rule, disputes between debtor and creditor were usually disposed of by arbitration, and the creditor had but little legal power to enforce his demands. He had to trust chiefly to persuasion and moral pressure, supported by an appeal to the religious feelings of his debtor. But this easy going arrangement, this friendly partnership between the ryot and the money-lender, was put an end to when, in accordance with English models, the British Government established civil courts in the rural districts, and thus placed a new and very sharp weapon in the hands of the creditor. The power and activity of these courts was gradually increased, and by the Civil Procedure Code of 1859 everything the ryot possessed was made liable to seizure and sale in execution—his house and his land, his plough and oxen, his bedding and his cooking utensils; even his clothing and that of his family was not exempted; and he was further liable to be arrested in default of payment and imprisoned in the debtors' jail. It is easy to understand how completely this change reversed the old order of things. The high rates of interest, 12, 24, and 36 per cent. which were before to a great extent nominal, became now a stern reality. And the creditor, holding in his hand a decree of the court, and attended by its bailiffs, was complete master of the situation. The process of the court became thus a sort of legalised torture by means of which all that the ryot had was squeezed out of him, and he became the mere bond slave of his creditor. The result was an angry antagonism between the two classes, ending in a financial deadlock. On the one hand, the ryot, sunk hopelessly in debt, lost all energy and enterprise; while on the other hand the business of the money-lender was paralysed: he was afraid to make new advances, and unable to recover either the interest or capital of his old loans. The situation and its causes cannot be more forcibly described than in the language of Sir George Wingate, the father of the Bombay Revenue system: "This miserable struggle between the debtor and creditor is," he says, "thoroughly debasing to both. The creditor is made by it a grasping hard-hearted oppressor. The debtor a crouching false-hearted slave. It is disheartening to contemplate, and yet it would be a weakness to conceal the fact, that this antagonism of classes and degradation of the people which is fast spreading over the land, is the work of our laws and our rule."

Such is the unfortunate financial position. The evil is apparent enough. Now let us consider (2) *the nature of the proposed remedy*. We have no heroic remedy to propose. Our objects are of a simple and practical kind. We want to conciliate the classes, to revive good customary village methods, and to restore the old friendly relations between lender and borrower. And these results we hope to obtain by organising a good system of agricultural banks, which are intended not to put aside the village money-lender, but to organise his operations, so that the business may go on smoothly for the benefit of all parties. In this matter we cannot expect much guidance from banking arrangements in England, where the tenure of land is so different from that in India. But, fortunately, in many other European countries we have the example of excellent credit systems specially devised for the benefit of small cultivators whose position is similar to that of the Indian ryot. In all these countries experience has shown that a good system of agricultural banks is absolutely essential for the prosperity of the class of peasant proprietors. It has been found that without such help they cannot maintain their position, and must inevitably

fall into the grasp of the local usurer. Accordingly these banks are universally regarded as State necessities of the first importance. The modern European system originated in Prussia more than a century ago, in the form of mortgage debenture associations, under the guidance of that sagacious monarch, Frederick the Great; and it is in Germany that agricultural banks have received their largest and most varied development, more than 2,000 such institutions being now actively at work with a business amounting to something like £150,000,000 sterling. Among German institutions the "Raiffeisen Agricultural Loan Unions" are specially deserving of notice, being peasants' banks conducted on co-operative principles. Similarly in Austro-Hungary, Italy, France, Belgium, and Switzerland, credit institutions on a large scale have been established for the benefit of the peasant class, private enterprise being the basis of these institutions, while the State gives them every support and encouragement. The Hon. M. G. Ranade, in a valuable paper read last year before the Poona Industrial Conference, gives the latest figures regarding the banks in each of these countries, and points out how liberal are the concessions granted by the respective Governments. For example, the Hungarian Government granted a subsidy of half a million of florins to the reserve fund of the Boden Credit Institute; while it exempts the bank's operations from all stamp duties; lends the help of its officers in assessing the value of property mortgaged; and permits the bank to foreclose or sell the mortgaged and also the unmortgaged property of the debtor, on default being made, without recourse to a court of justice. In France, the Government guarantees the *Credit Foncier* against competition, and lends the assistance of its officers. And similarly in each country direct and active support is given according to local requirements. The result is that an immense business is done at the lowest possible interest, and with the least possible friction and expense. Thus, in France, since 1852, 3,400 millions of francs have been advanced to the landholders through the *Cérdit Foncier*, and the current rate of interest has thus been reduced from 9 or 10 to 5 per cent. In Switzerland, the system is very complete, nearly every canton having its separate mortgage bank. It appears that the Berne Bank has within the last fifteen years been able to reduce its rate of interest from 5 to 4 per cent., the result being that it has nearly trebled the volume of its business. The deposits have increased from about £1,000,000 to over £3,000,000 sterling, and the loans from £1,600,000 to £3,200,000. In the Australian Colonies land credit companies have attained a large development, but I do not lay so much stress upon them because their dealings are for the most part with large land-holders, whereas the European system is suited to small cultivators like the Indian ryot.

As regards methods of working, there are of course differences of detail in different countries. But all these institutions operate chiefly with borrowed capital; and the secret of their financial success consists in this, that they keep down the amount of the shareholders' paid-up capital, upon which a dividend has to be earned, while making their loans out of capital borrowed from the general public at low rates of interest. The bank thus occupies the position of a credit institution between the cultivator, who must have capital to work his land, and the general public who desire a safe investment without the trouble of inquiring into the individual borrower's title or credit. And the profit for these good offices consists in the difference between the two rates of interest. Thus at present the average Indian ryot pays 24 per cent. to the village money-lender. We propose to commence by letting him have the advances he wants at 9 per cent.; and we expect to be able to borrow at less than 5 per cent. Let us see how that would work out as regards the prospects of our experimental bank, operating on the mortgage debenture method. Borrowing at 5 per cent. and lending at 9 per cent. the bank would have a working margin of 4 per cent. on all its operations. If therefore it had a paid-up capital of £100,000, and passed £1,000,000 sterling through its hands, it would realise a gross profit of £40,000 a year, equal to 40 per cent. upon the paid-up capital, an amount sufficient to yield a large profit to the shareholders after providing for all expenses and unfavourable contingencies.

I now come to the last portion of my subject, (3) *our attempt to apply this remedy* in the case of the Indian ryot. In making this attempt our object was to frame a scheme upon the lines of the Continental system, while adapting the details to local circumstances. Especially we had to provide for the settlement of the old debts; we had to restore the friendly relations between the ryots and the village money-lenders; we had to secure for our project the hearty co-operation of

both these classes; and we had to induce the local native capitalists to give our scheme their financial support. Last but not least we had to claim from Government concessions similar to those accorded to such institutions on the continent of Europe. In Europe, as we have seen, it has long been the recognised duty of the State to see that well organised banks are established for the benefit of the peasant class. Private enterprise has been found to be the best basis for such undertakings. But this fact is not held to diminish the responsibility of the State. And when private enterprise is willing to work on the lines approved by Government, the Government gives the banks every possible support, the public credit being utilised to strengthen their financial position, while the machinery of the State is made freely available to facilitate the recovery of their advances. In making our claim for similar concessions on behalf of the India ryot, we felt that in India a similar responsibility rested upon the Government, and in a higher degree than in Europe; because in India Government is the universal landlord, and is therefore more directly responsible, in its administrative capacity, for the welfare of the cultivating class; also as regards legislation, the Government of India retains all the power in its own hands, and is therefore solely responsible for providing the required remedy.

These were the conclusions which formed the basis of the scheme which originated in Poona at the close of 1882. For a considerable time before careful inquiries had been made, and many local meetings held in order to learn the wishes of all parties concerned, and to explain to them the nature of our proposals. At last all was ready. The ryots gladly welcomed the proposal; the village money-lenders were prepared to co-operate; and the native bankers were ready to provide capital. A public meeting was then held at Poona under the presidency of the collector of the district, resolutions were passed for the establishment of an agricultural bank, and an influential committee was appointed. This committee, representing the promoters, waited upon the Governor (Sir James Fergusson) and set forth their proposals, stating that they were willing, upon certain conditions, to establish an agricultural bank for the Purandhar Taluka of the Poona Collectorate, as a private undertaking. They proposed that the capital of the bank should be one crore, the paid-up capital being 20 lakhs of rupees; and the main conditions were that the Government should appoint a Commission to effect a settlement of the old debts within the Taluka, by means of a voluntary liquidation; and that in case of default the advances of the bank should be recoverable by summary process through the revenue authorities, instead of by regular suit in the civil courts. H.E. Sir James Fergusson received the deputation in a very cordial manner, and said that in the Australian Colonies he had had experience of similar institutions which had proved very successful. He expressed himself personally favourable to the scheme, and promised that he and his colleagues would give it their best consideration.

Our proposals reached the Viceroy in Council at a favourable moment. It had always been the policy and wish of the Indian Government, as general landlord, to help the ryot with loans for land improvement. But from various causes the attempts to make these advances through official agency had failed in every part of India. And the Government had at last come to the conclusion that it must look to private enterprise for any real progress in this direction. The Marquis of Ripon was then Viceroy, and Sir Evelyn Baring, who was then Finance Minister, had personal experience of the Egyptian Credit Foncier, so that the Poona scheme received immediate and sympathetic consideration, as providing the exact means desired to carry out the Government policy. And a very important despatch, No. 638 R, of 5th December, 1882, was sent from Simla to the Bombay Government, expressing the satisfaction of the Viceroy in Council with the proposals made, and setting forth in detail the action which the Government were prepared to take. Subject to certain minor conditions, the Government accepted the Poona proposals. They were willing to appoint a Commission for the liquidation of the ryot's debts within a limited experimental area; they would advance, in the first instance, the cash (some 6½ lakhs) necessary for the composition of these debts; they would, as regards the bank, remit a part of the stamp duty on documents and the court fees in suits; and they would concede to the bank the privilege of recovering its advances through the revenue officers as arrears of revenue. While granting these important concessions, the Government of India were careful to explain to the Bombay Government that similar privileges would not necessarily be granted in future to other similar

banks. The Poona Bank was, in fact, treated as a pioneer enterprise; the object being to make a practical experiment in a limited area, with the hope that when the system was once established and found to be workable, it would spread wherever needed, and, to use the words of the despatch, "prove of incalculable benefit to the whole country." In conclusion, the Government of India stated that they attached very great importance to the experiment, and asked the Bombay Government to undertake the working of the measure. In reply, the Bombay Government, in their despatch of 5th April, 1883, stated their willingness to give the scheme a trial.

In this way, after no little labour and negotiation, every interest and every authority in India has been brought into substantial agreement as regards the scheme. And on the 31st May, 1884, a despatch, signed by the Viceroy and his colleagues, was forwarded to England, setting forth fully the circumstances of the case, and asking the sanction of the Secretary of State to the proposed experiment. "We are anxious," they said, "to give effect to a scheme which we believe to be advocated on purely disinterested grounds, which can, under the experimental conditions proposed, be carefully watched, and which is likely, if successful, to be productive of much benefit to the country." Nothing now was wanted except the formal sanction of the India-office. But this was just what we could not get. How the project suffered shipwreck, and how our labour came to nought, I will presently relate. But before doing so I ought briefly to describe the friendly reception which was accorded to the scheme by public opinion in England. While the negotiations were still proceeding in India I went home on furlough, and was asked by the bank promoters to do what I could to make the scheme known in England. Accordingly, on arrival, I communicated the whole circumstances to two of India's best friends, Mr. John Bright and Sir James Caird. They sympathised warmly in the scheme; and Mr. Bright consented to take the chair at a meeting held at Exeter Hall on the 5th July, 1883, under the auspices of the East India Association, when I read a paper on "The Poona Ryots' Bank." A discussion followed, in which Sir James Caird and other high authorities took part. The chairman's speech, and the debate generally, were strongly favourable to the scheme, and next day the *Times*, *Daily News*, *Standard*, and other London papers gave their approval to the proposal. Next it was necessary to make the scheme known in Lancashire. And accordingly, on the invitation of the Directors, I read a paper before the Manchester Chamber of Commerce, under the presidency of Mr. G. Lord, the chairman. The paper was entitled "Government Concessions to Agricultural Banks in India." A resolution in cordial support of the scheme was moved by Mr. John Slagg, then senior member for Manchester, and seconded by Mr. (now Sir William) Houldsworth, M.P., and was carried unanimously. And in accordance with a further resolution this expression of opinion was forwarded to Her Majesty's Secretary of State for India. Further, a Corresponding Committee was formed, including the Chairman and Deputy-Chairman of the Chamber, in order to give the scheme continuing support. Finally, with a view to placing the bank's debentures on the English money market, it was thought desirable to approach the authorities of high finance in London. Accordingly, on the introduction of Mr. Bright, I had an interview with Sir Nathaniel Rothschild, M.P., who had already expressed himself interested in the subject. He informed me that, if addressed by the authorities at the India-office, and satisfied regarding the terms that would be granted, he would be prepared to give the scheme favourable consideration. He added that if the terms seemed satisfactory from a financial point of view, he did not think there would be difficulty in obtaining the capital necessary for the proposed experiment.

There only remains to tell the sad conclusion of the tale. I have to show you how the scheme to establish agricultural banks in India was defeated: how our poor little ship, the object of so much care and labour, was wrecked almost in sight of land. In order to properly appreciate the action of the India-office in this matter, it is necessary to bear in mind its position and responsibility with regard to this movement in relief of the ryot. We must remember that the great mass of the Indian peasantry are in a condition of extreme danger; they have no savings or stock of food, and consequently die in hundreds of thousands if there is one failure in the periodical rains; worse still they cannot hope to make savings, being deeply sunk in debt, while their ancient system of credit has been shattered by the action of our civil courts. For all these matters the Government is directly responsible, both as general landlord and as the sole depository of all political

power. Fortunately a remedy exists by which this danger may be averted and the ryot placed in a position of safety; this mode of treatment has been tested under the most varied circumstances, and has invariably proved successful in practice; and in every civilised country the duty of the State to see this remedy applied is acknowledged. In India the authorities are desirous of giving the remedy a trial in a cautious experimental way; all public opinion in India and in England has declared itself in favour of the movement; only the India-office at Westminster stands in the way, and forbids the experiment to be tried. It seems almost incredible, but such is the fact. How the scheme was baffled by delay; how the promoters were wearied out by interminable correspondence on theoretical points of difference; and how finally the proposals were met by a point blank refusal, will be found set forth in a Blue-book of 72 closely printed pages, obtained at the instance of our present chairman. The final answer was given on the 18th of August, 1887, in the House of Commons, by the Under Secretary of State for India, in answer to the following question, of which Mr. S. Smith gave notice:—"Looking to the indebted and depressed condition of the Indian ryot, to ask what steps are being taken to carry out the practical experiment proposed by the Government of India in their despatch No. 658 R. of 5th December, 1882, with a view to introducing into India the system of agricultural banks which have proved so useful in Germany and elsewhere in providing the peasantry with capital at moderate rates, and in protecting them from the exactions of small usurers." To this Sir John Gorst's answer was that "the proposals made in the letter referred to by the Honorable Member were carefully considered in 1882 by the Secretary of State in Council, with the result that it was determined that they were not capable of practical application." Now, was not this a most extraordinary answer, and a most extraordinary decision? These gentlemen sitting at Westminster had not been in India for years; they were not practical bankers; they had no special knowledge either of the continental system or of the banking requirements of the Poona district, where the experiment was to be made. Yet they assumed to know what was practicable there better than the bankers of Poona and the Government of Bombay: they made up their mind that agricultural banks could not be introduced into India, and decided that the Government of India must be prevented from making the attempt. What were the reasons for such an unusual exercise of authority? Was it denied that the ryot was urgently in need of help? No. Was it pretended that the objects aimed at were not most beneficial and most important? No. Was it alleged that the proposal of the Government of India trenched upon any accepted principle or policy of Indian administration? Again, no. The reasons for the refusal are set forth in the India-office Despatch No. 95, of 22nd October, 1884; and it will be found that the objections refer to matters of detail, and are of a speculative kind. For example, it is objected that the scheme professes to be one of private enterprise, whereas in reality the bank will be a Government institution; again it is contended that the financial calculations of the Poona bankers do not show that the business will be profitable; and it is argued that the condition of the ryot is either too good or too bad to be suitable for the operations of an agricultural bank. The only objection that can at all be called a practical one is that which has reference to the coercion of defaulting debtors, and this objection is founded upon a misconception. The despatch takes exception to the proposed concession under which the bank's advances may, in the case of a defaulter, be recovered as a revenue demand. This is objected to from the fear, to use the words of the despatch, lest Government should "incur all the unpopularity and odium of collecting debts which, though private obligations, are treated as public demands." This objection evidently arises from a misapprehension, the Secretary of State being under the impression that the Government proposed to undertake the collection of the bank's debts. There could not be a greater mistake. Both the distribution and collection of the bank's advances was to be done entirely by the paid agents of the bank. The question was one of jurisdiction, not of collection. With its moderate rates of interest, and with its desire to show forbearance to its debtors, the bank expected very seldom to require any compulsory process. Still it was necessary that some ultimate means of coercion should exist; the only question being whether this compulsion should come through the costly and cumbrous machinery of the civil court, with its lawyers and bailiffs, warrants and executions, and sales of land; or whether it should come through the simpler and cheaper methods of the revenue courts, in which case the village officers

would exercise their customary authority, preventing the defaulter removing his crops until he had paid the instalment due to the bank. All that the Government of India proposed was that when compulsion was required, the less grievous method should be preferred, the method which Government itself employed when recovering its own agricultural advances from defaulters. As regards "unpopularity and odium" arising from coercive process, Government will have to bear that, whether the jurisdiction is exercised in the judicial or in the Revenue department. The masses in India make no distinction between the Revenue and judicial departments; to them these two departments are equally the "Sirkar" or Government, while the educated classes know that the Executive Government, as the sole legislative power, is responsible equally for the constitution of the courts and the revenue administration. The only difference is that if the Revenue machinery is employed there will be less friction and less hardship, and consequently the unpopularity and odium falling upon Government will be less in amount.

I do not know whether I need say anything further in answer to this objection. But perhaps the situation may be made more clear by the help of an illustration which I have already employed. Let us suppose that Government, wishing to irrigate certain thirsty lands, puts up a great pumping engine to raise and distribute the water, intending that this machinery should be worked by its own servants. But its servants, not being professional engineers, are unable to work this machinery successfully. Consequently the land remains unirrigated. In this difficulty a respectable and competent firm of engineers come to the help of Government, and offer to carry out the work of irrigation upon the lines approved by Government. The Government gladly accepts this offer, and recommends that the engineers should be allowed the use of the machinery for this purpose. Would it not be considered the height of absurdity if the India-office refused to sanction this arrangement? Yet such a refusal would be on all fours with the present case. To supply capital to the ryot, Government is willing and anxious to advance cash out of the Treasury, and to employ the time of their revenue officers in distributing and collecting these advances. Further, Government passes a law to make such advances recoverable as arrears of revenue. But experience has shown that revenue officers have neither the time nor the qualifications for successful money-lending. So Government welcomes the offer of the Bank promoters, who are experts in this business, and are willing to carry out the objects of Government. Originally the Government was willing to do the whole work itself. If it is relieved of three-quarters of the burden why should it hesitate to bear the remainder? The Bank promoters are willing to give their professional skill; to bear the cost of distribution and collection; and to risk their own money instead of the money of Government. There is no reason why Government should hesitate to do what remains to be done, and give them the free use of the simple and effective machinery provided by law for the recovery of agricultural advances; The more so because without these facilities the bank would be driven to employ the costly and oppressive machinery of the civil courts, and thus create afresh for the ryot the very evils which we desire to remove.

For any further discussion of these questions I would refer to the Blue-book, where the objections raised by the India-office are patiently and fully answered by the Poona Committee. But I do not attach much importance to any dialectic victory in such a controversy. Our main contention is that the time for academic discussion is long past. What we now want is a practical experiment. It is the old story of the live fish and the full bowl of water. The philosophers proved, by good metaphysical arguments, that if the fish was put into the full bowl the water would not overflow. And this held good until some one of less subtle mind tried the experiment and found that the philosophers were in the wrong. So, in the present case, we desire to bring the question to the test of experience. We want a pioneer bank to be started, without delay, on the lines above indicated, and we believe that in this way a system will gradually be worked out free from practical objections and well suited to the special needs of the Indian ryot.

My story is now ended. I have tried to bring before you the terribly precarious condition of many millions of our fellow citizens—gentle, industrious, law-abiding peasants. And I have indicated one of the measures most urgently required in order to place them in a position of safety. We do not say that this remedy alone will produce prosperity. Many other reforms are urgently needed. But this measure is so simple and practical, so completely in accord with the general policy of the administration, so free from any collision with

vested interests, that its immediate adoption seems quite unobjectionable. It is indeed surprising that any one should be found going out of his way to oppose such an interesting effort of self-help and public spirit. In conclusion, I would most earnestly ask you to bring public opinion to bear upon the India-office with regard to this great economic question. The present time is most opportune for two reasons: 1st, because even now the shadow of famine is over the land. No doubt the public officials will do what they can to save life and relieve suffering. But this will be done at a vast expense, which can ill be afforded. We want to remove the originating cause of such disasters, instead of merely mitigating the effects by means which pauperise and degrade. And the second reason is that public attention in India is now being particularly directed to the necessity of organising agricultural credit. The subject was prominently brought forward at the recent Poona Industrial Conference. And, at its last session, the Indian National Congress included the establishment of agricultural banks in its programme of Indian reform. I also observe, with much satisfaction, that the Madras Government has taken up the subject, and has appointed a special officer, Mr. Nicholson, to collect information regarding agricultural banks, at home and abroad, and formulate a scheme for the consideration of Government. May the scheme prosper; and when it comes up for the sanction of the India-office, may the authorities look favourably on it, not unmindful of the injunction of the Eastern law-giver, whose words seem intended for the present case: "Thou shalt not harden thine heart, nor shut thine hand from thy poor brother; but thou shalt open thine hand wide unto him, and shalt surely lend him sufficient for his need."

DISCUSSION.

Lord REAY, G.C.S.I., said he had great pleasure in thanking Sir William Wedderburn for having again revived this important subject. It was not a new subject to either of them, as they had treated it officially, and therefore, he was very glad to greet it on that platform as an old friend. He should have preferred to hear the arguments against the scheme by many gentlemen present with longer and wider experience of India, but unfortunately, he had to attend another meeting, and before leaving he wished to support in the main the views which had been enunciated in the paper. It was impossible at such a meeting to enter into the details of the Purandhar Taluka scheme, and he thought his learned friend had very wisely abstained from giving the details. What the meeting had to do was to show their sympathy for the main principles stated in the paper, that it was the duty of the Government in India to assist institutions which rested on a solid financial basis, and which had for their object to give credit, at a low rate of interest, to its agricultural subjects. The Government of India had a direct interest in good agriculture, and solvent occupiers were the first condition of good farming. When in England they were placing the credit of Government at the disposal of proprietors who did not as yet exist, surely in India they might place the credit of the Government at the disposal of existing proprietors, in order to keep them on their legs. Without some such scheme being adopted, as had been pointed out before, there was great danger that the ryotwari system in Bombay would be transformed from a small-holdings system into a zemindari system of larger properties—a transformation which everyone would deprecate. It would be a curious comment if, while legislation was all in the direction of creating a smaller proprietary in England, we should do nothing to prevent small properties being absorbed by capitalists in India. This was actually going on in the neighbouring districts of Bombay. With reference to the statement in the paper of the large amount of money locked up in the banks, this statement probably referred to certain periods of the year. It was due to some fault in our banking system that at times there was such a glut of money that the rate in Bombay fell to 2 per cent., when the rate in London was higher. But at times, when the export trade was brisk, the rate of interest rose considerably. This was an important banking question, and he merely alluded to it to show that they had to deal with very great fluctuations in the rate of discount. There was one omission in the paper to which he should like to refer, as it related to a somewhat important matter. Sir William stated that the friendly relations between the debtor and the money-lender were increased by the fact that under native Governments, and in the earlier days of British rule, disputes between them were usually disposed of by arbitration. But one of the objects of the Deccan Relief Act, which had not been mentioned in the paper, was to restore arbitration. The Act did establish conciliators for that very purpose. He supposed Sir William would retort that the clause of the Deccan Relief Act had remained a dead-letter; and he was afraid there was a great deal of truth in this, but, at the same time, the fact remained that the Indian Legislature certainly wished, when that Act was passed, to establish a better and inexpensive form of procedure between debtors and creditors. No doubt Sir William would also say that the Deccan Relief Act impaired the credit of the ryots, and made it more difficult to obtain money at easy rates. But to this the answer would be that it certainly was not in the

interest of the ryots to increase unduly the facilities which create a condition of insolvency which place him in a helpless situation at the mercy of the money-lender. With regard to the statement as to the bank in Hungary having the right to foreclose, he should like to have some assurance that it was not proposed to give a power to the banks in India of foreclosing without going to arbitration.

Sir WILLIAM WEDDERBURN—Certainly not.

Lord REAY said that in France an experiment had been made by the Bank of France, which advanced in the Nièvre money upon condition that the directors of the Agricultural Society of that Department, who were well acquainted with the financial position of every farmer and landlord, gave their signature. The bank advanced money to the advantage of the agriculturists of the district with perfect safety. If by any chance those who might speak after him were of opinion that this experiment should be tried, not in a whole *taluka*, but on a smaller scale, Sir William would probably not object to this. Like many other questions in India, the present question could only be solved by experience, and, therefore, it was important that we should make some beginning, and cease the triangular correspondence between the Government of Bombay, the authorities at Simla, and the India-office. It was possible that, in some parts of India, the conditions under which this experiment could be tried would be more favourable than in so poor a district as the Deccan. There was one difficulty which he did not want to obscure. He saw it stated that the village money-lenders were prepared to co-operate in this movement. This was a very important statement, because, from the dim recollection which he had of some of the records upon the subject, he knew it was one of the most formidable arguments raised, that, from the moment the bank charged 9 per cent. interest, the money-lenders would charge 8 per cent. or 7 per cent. By this means the scheme could be imperilled if not defeated. If the money-lenders were given some position in the bank, this might be avoided, and their knowledge would be useful. Notwithstanding all his efforts to encourage takavi advances, there was not much progress made; and one of the difficulties was, that the native officials, on whom the responsibility mainly rested of carrying them out, were reluctant, being afraid that the advances might not be repaid when the time came. It was, however, the duty of the Government to face a certain amount of risk where these advances were needed by deserving agriculturists, especially to counteract the influence of bad seasons.

Sir CHARLES BERNARD, K.C.S.I.—I am sure that we of the Indian Section of the Society of Arts are deeply indebted to Sir William Wedderburn for the very interesting paper we have just heard. As he says, the indebtedness of the classes connected with the land is one of the most important of Indian questions. The ryots of India will ever be grateful to Sir William Wedderburn and his Poona friends for the zealous and able way in which they have investigated the subject and placed it before the public. Sir William has unfolded his view of the case with a clearness which we must all acknowledge, but I am not sure that the whole case has been fully stated. Much fault has been found with the action or inaction of the India-office. I have no brief to defend the India-office, which, being absent, is naturally found to be in fault. But these things were not done in a corner. The grounds on which the India-office acted are explained in papers presented to Parliament nearly six years ago, at the instance of our chairman, whose sincere interest in the welfare of our Indian fellow subjects we all acknowledge, and to whom we are most grateful for being present this evening. All who are interested in the subject have no doubt read this Blue-book, and I will not trouble you with any discussion thereon; but it is perhaps worth mentioning that Lord Kimberley's despatch of November, 1884, of which the reader of the paper has spoken, recognised most emphatically the importance of the question, signified a disposition to entertain favourably any practical proposal for the relief of the Indian peasantry from indebtedness, and promised the most careful attention to any revised scheme for promoting the objects in view. I may not trouble the meeting with general remarks regarding the Indian village banker, who is by no means the wealthy Shylock that he is often represented to be. His services to the landed classes are most valuable; he keeps the ryot and his family on their legs; without his assistance the village polity could not be kept going; and though his rates of interest may sound high to English ears, yet there must be many counterbalancing losses in his business, for the Indian village banker usually lives poorly, and is very rarely a rich man. Nor will I stop to point to the risk of making borrowing too cheap and too easy for the ryot. In Burma, where the interest on rural loans ranges from 2½ to 5 per cent. per month, even where good security is given, it has been found that only 2 per cent. of the ryots were hopelessly involved, while only 15 per cent. owed more than they could repay in a single year. Many of us believe that the Indian peasant would not have been indebted to the extent he now is, if he had not been prematurely enabled by British laws to borrow money easily on the security of his land. As has been said, Lord Kimberley invited the submission of a revised scheme from India, but, as yet, such is the difficulty of the subject, no revised scheme has been matured. I hope that some scheme of the kind may soon be forthcoming. The reader of the paper mentioned that Mr. Nicholson, of the Madras Revenue Service, who has closely studied the subject of agricultural banks in Italy and Germany, and has published interesting papers thereon, has recently been deputed by Lord Wenlock to report upon the matter; and

received a letter from him last week, saying that he hoped soon to have his report ready. So I trust that before long a revised scheme, such as Lord Kimberley suggested, may be received from India. Like most other Indian revenue officers, in more than one province, I have had to consider the question of rural inbebtedness, and watched with great interest the Poona discussions and proposals. I was employed in another part of India when those proposals were sent home, and when Lord Kimberley's despatch came out; and I confess to having felt relieved when it became known that the Poona proposals were not to be carried out in their entirety. The Purandhar scheme was intended to be a pioneer scheme, on which, if it succeeded, similar arrangements for other parts of India might be modelled. Yet the authorities who sent forward that scheme admitted the questionable character of some of its provisions, and were careful to say that they could not undertake to apply those questionable provisions to other parts of India. To me it seemed that the Poona scheme could not have been practically successful, and could never have been made generally applicable to other parts of India. If my view—which was probably shared by many revenue officers—was correct, then the Poona scheme, if it had been sanctioned, might, by its failure, be thrown back. The shortcomings of the Poona scheme were, to my mind, these:—First, the undertaking was on too big a scale, and tried to do too much at the outset. A general settlement and liquidation of all the debts of nearly all the ryots in the country treated was to be made. The settlement was to be made by the executive officers of Government, and the money was to come from the funds of the general taxpayer. Then the bank was to come in—was to give fresh loans to the ryots, who had thus been made solvent, and was, by and bye, to pay off the money advanced by the Treasury, if it could. No doubt the tract would have been solvent and prosperous for a time, and the ryots would have merrily contracted fresh debts to the bank, which, in its turn, was to borrow money on debentures in England. But if the advance made by the general taxpayer was ever repaid, I fear the last state of the tract would have been worse than the first. I question if English capitalists would have advanced money to the bank without some understanding with the Government, which would be interpreted into a Government guarantee directly the bank got into difficulties. Some proportion—possibly a considerable proportion—of the borrowing ryots, who had been taken in the mass without selection, would be behindhand with their payments, from one cause or another, and so the difficulties of the bank would begin. In Germany, and especially in Italy, where circumstances most resembled Indian facts, the rural banks began on a small scale. There were a great many of them, they were managed by local people, and they got the local money-lenders and the local farmers to take shares; they began with only a few clients at first, and they gradually—though, in most cases, very rapidly—extended their business. In India, too, the business must begin on a small scale, and tentatively; and it should not be heralded by a general liquidation of all rural debts at the cost of the general taxpayer. Each bank or local branch should secure the co-operation of one or more of the village bankers and solvent ryots as shareholders; these men would know what ryots could be trusted and what could not. For the rural banks, if they are to succeed, must select their clients; and with a number of local shareholders—as in Italy—the banks would be likely to select discreetly and to exercise constant vigilance over borrowers. Secondly, the Poona scheme relied too much upon Government help. At the outset it required a general settlement of debts all over the country by the agency of Government officers and from the Public Treasury. Then —and this seems the worst feature of the whole—the executive officers of Government were to step in and realise the bank's debt from borrowers who would not pay. The process by which arrears of Government revenue are collected is, that the collector certifies as to the arrears; his certificate has the force of a decree, and can be enforced just as the decrees of a civil court are executed. Who would give the certificate in the case of the bank? If a borrower claimed that the account against him was wrongly stated, that interest was overcharged, or that his payments were not duly credited, who would try these issues? Surely the collector and his staff could not find time to try them properly. Such issues could best be decided by the civil courts. Twenty-three years ago rent suits in Bengal—which are the burning questions in that province—were transferred from the jurisdiction of the collectors to the civil courts; and it is matter of common knowledge that the poorer parties in these cases—about 200,000 suits a year—get better justice under the present system than they did under the old. So with issues between ryots and bankers, the ryots will in the long run fare better in the civil courts than under the executive arrangements of the collector. I greatly question whether the Indian Legislature would be generally ready to apply the collector's executive jurisdiction to disputes between the ryots and rural banks. It was only last month that the Indian Legislature refused to pass a Court of Wards Act for Bengal, until the Government gave a pledge to take measures for preventing arrears of rent on Wards' estates from being realised under the collector's executive authority, or under the certificate procedure, as it is called. These two faults—namely, attempting too much at once, and relying too much on Government aid—would, I believe, have wrecked the Poona scheme, if it had ever been launched. And the experience gained would only have been of a negative kind, showing mainly what courses must be avoided. If a revised scheme is brought forward of a more practical kind, under which rural banks should start from small beginnings, as purely local institutions, and under

which the banks should only have the ordinary remedy against their debtors, then, I think, the establishment of such banks should be sanctioned, as experiments, in one or more districts of every province, where the people and the collector for the time being may be ready to work the scheme. And, in that case, I think the State might reasonably help rural banks by some such concessions as the following, namely:—(*a*) The loan of public money at 4 per cent. per annum, on the security of the bank and all its assets, in proportion of one rupee of public money for every two rupees of actually paid-up private capital; (*b*) the reduction of all stamp fees by one-half, or even two-thirds, on litigation, and on deeds for a period of (say) ten years, to begin with; (*c*) the remission of registration fees on documents for five years, and the reduction of fees by one-half for five years more; (*d*) the auditing and publication of the bank's accounts by the public officers once in every half year; (*e*) the custody of the bank's cash, beyond a certain minimum, and of the bank's securities in public treasuries and sub-treasuries. As I have said, I have no authority to speak for the India-office, and I cannot say how a revised scheme of this kind might be viwed by the highest authorities, but I have, on the invitation of your chairman, so far as time allowed, expressed my own views on a subject of really paramount interest to the bulk of the Indian population.

Mr. A. ROGERS said, although he entirely concurred in the principle of agricultural banks, his chief objection to the proposed scheme for India was that the bank would be impracticable, owing to its not being able to compete with the local money-lender. In order to do this, the bank would require to have a branch in every single village. As was well known to all Anglo-Indians, almost every village had its money-lender, and this person also acted as a grain dealer and pawnbroker, and with him the ryot had a running account. It was impossible that any bank could compete with such persons. The ryot did not want a certain sum of money once a year, but a varying amount perhaps as often as once a week. It would be impossible for the bank to have branches in every village; and unless it did so, it could never compete with the local money-lender. The scheme would not thus be a financial success, and must ultimately break down. With regard to the change in the friendly relations between the money-lender and the ryot, which had been referred to, he thought Sir William Wedderburn had not traced this to its true cause. It was due to a change that was made in the law. Under the former Bombay law a running account went on for twelve years, which enabled the parties to it to look round them and arrange with each other, but upon the twelve years being cut down to three, the money-lenders, in sheer self-defence, took to putting their debtors into court and getting decrees against them. Had this change in the law not taken place, the amicable relations which formerly existed between creditor and debtor would not have been disturbed. The best thing one could do in order to restore these amicable relations would be, as far as possible, to restore the old state of the law, and allow a longer period within which the money-lender and debtor could come to terms. It was said in the paper that 40,000,000 people in India were continually on the verge of semi-starvation, but if such were the case, he thought the population would not have increased by 80,000,000 in the last decade. The Government was doing all it could in order to place the ryot in a proper position of independence. The land tenure in Bombay was most favourable; a man got a full proprietary title to his land, and could mortgage or sell it very quickly, the system of transfer being of the most simple possible description. The Government were also prepared to make taccavi advances. He could not quite understand how the pressure of population upon the land, to which the ryot's indebtedness was chiefly due, could be remedied by agricultural banks.

Surgeon-Lieut.-Colonel HENDLEY C.I.E. thought it would be better to lend in kind or seed than money. It was contrary to his experience that the agriculturist was thrifty, for he believed a ryot spent all the money he earned in times of prosperity on marriage and funeral expenses. In fact, he often went out of the way, and created the necessity for spending money. He quoted from a friend, a native noble, who stated that the cultivator did not lose by the rent, but was kept in poverty by extravagant expenditure on marriages, &c. A short time ago he himself employed a mechanic to make some brass vessels. He was very successful, and made a deal of money; but the first year he spent nearly all in celebrating his father's funeral; and he then went back to his grandfather, and spent the remainder on *his* funeral ceremony. One of his (Dr. Hendley's) clerks spent his own income, his brother's income, and that of his father for two years upon the marriage ceremony of certain of his children. In Rajputana the nobles had formed a society, chiefly under the inspiration of Colonel Walter, lately agent to the Governor-General, for reduction of such expenditure, and so far it had been worked most successfully. This showed how much they felt the necessity of reform, and he (Dr. Hendley) hoped that their good example would be followed by the lower classes. In establishing these banks, it was very necessary to see that the ryot did not have the easy handling of too much money, and that he should be kept under proper control by the village authorities. The most important point of all was to make it as difficult as possible for the ryot to get cash, though we ought to do our utmost to provide him with seed and subsistence in times of scarcity, and to teach him to be provident. The great desire of the ryots in some Native States, where the central authority was weak, was to live on the estates of nobles rather than Government land, as in the latter case the collec-

tion of the rent fell to an agent, who had no heart in the matter. One of the most important things in India was to protect the nobles and the people against the middleman. It would be more to the advantage of the nobles if we taught them less of the power of passing a successful examination at the university than how to deal justly with their ryots, and to protect themselves against the agents who preyed upon them. In some of our noble's colleges he believed this was done. Speaking for himself, he might say he was as much in sympathy with the nobles as with the ryots.

Dr. A. J. VOELCKER said that when he was in India some time ago, he tried to ascertain some of the causes of the indebtedness of the Indian people, and the conclusion he had come to was, that the existence of the money-lender was a result of the indebtedness rather than the cause of it. Money-lenders would not go to a place if there were nothing to be got from it, and one sign of true poverty was the scarcity of money-lenders. The secret of the present position of the ryots rested very much more with themselves than Sir William Wedderburn would have one believe. The principal cause of the misery was the improvidence of the people; and, if they had their old debts paid off and further money advanced, he did not believe that they would, as Sir William Wedderburn imagined, at once proceed to dig wells and to manure the land. The ryot often would not use canal water, in order to increase his crop and get more off his land, but he would only begin to use it when his crop was actually about to fail. When in Madras, he came across an interesting instance of the the cultivators of the soil combining together to form a co-operative association for the purpose of protecting themselves against the extravagant charges of the money-lenders. Instead of paying 25 per cent. or more, money was lent by the association to its members at 12 per cent. A measure like this would, he thought, go farther than the establishment of agricultural banks towards the improvement of agricultural credit.

Sir STEUART COLVIN BAYLEY, K.C.S.I., thought there were one or two points which had not yet been brought forward by previous speakers which he would refer to, and, if possible, he hoped the reader of the paper would help him to come to a conclusion upon them. He had taken a strong interest in this question from the beginning, having been a member of the Government of India when the subject was under consideration, and more especially responsible for the despatch wherein the recommendation to which Sir William Wedderburn had alluded went home. He might excuse himself now from saying anything further about that, except that he was still in principle strongly in favour of that or some similar experiment being tried. He did not recede one iota from that point of view when he said there were some objections to it which had not been properly met. The objections which the Secretary of State took would be supposed by anyone who had only heard what the reader of the paper had read, to arise from want of sympathy, hard-heartedness, and a desire to obstruct what was really an obvious blessing to the poorer agriculturists of the Deccan. The real grounds on which exception was taken to the proposal were distinctly practical. It was urged that, after the ryot had been relieved of his previous debts by Government money, he would have first of all to pay off the amount which had been advanced, and this was calculated to occupy twenty years, and during that time he would have to pay his assessment as well, so it was not quite plain where the surplus income at his disposal was to come from on which he could go to the bank and borrow. Another objection was, that the bank would come into competition with the ordinary village sowcar but would not be able to oust them; that was to say, the ryot would have to go to the sowcar for a continuous supply of petty loans, and the result would be that the latter, having had the cream of his business taken away by the banks, would be forced to increase his rate of interest, in his dealing with the ryots on the smaller matters. They were told that the intention was to bring the money-lender into connection with the banks, which was also proposed in the Ghoozerati scheme, but he had never yet seen how it was proposed to work out this plan in connection with the Purandhar taluka scheme. It was important, and he would be glad to have some further explanation of the *modus operandi*. The chief objection, however, was to the recovery of dues by the Government officials. The reader of the paper thought there must be some misapprehension upon this subject, but the papers that went home were as clear as they possibly could be about this. He did not think there could be any misapprehension upon the matter, though there might have been a difference of opinion. The Secretary of State probably imagined, that although the intention was only to resort to Government officials as a last resource, yet, as a matter of fact, when the bank found any difficulty in collecting its dues, if all they had to do was to hand the paper of claims to the collector, they would have recourse to that very simple and easy method of recovery very often. Those were not obstructive objections, but practical objections to the scheme, which had to be met, and the correspondence with the Secretary, of State so far as he knew, ended there. His own information only extended up to 1886. The case then stood thus. The Secretary of State had made his practical objections; he had asked that the scheme should be reconsidered in the light of these objections; and he further said he would be glad to give his favourable consideration to a revised scheme. The committee that had, in the first instance, investigated the scheme put forward a paper of answers; and at that stage he (the speaker) left it. He knew that the matter was referred to the Government of Bombay, but he did not know whether the committee

at Poona had ever tried to make such alterations as would meet the objections. He should be very glad if the reader of the paper could tell them exactly what had happened after that point, and also if the objections could not reasonably and fairly be met. For instance, was it essential that you should go to the revenue courts for assistance in attesting the revenue debts. The matter did not seem to him to be one so entirely for denunciation of the Secretary of State as Sir William Wedderburn would have them believe.

Sir GEORGE BIRDWOOD, K.C.I.E., C.I.E., said he was not entitled to express any opinion on the subject of Sir William Wedderburn's paper. It was true he had lived many years in India, but India was not a single country, but a continent of many countries, and you might know a great deal of one part of it without knowing anything worth acceptance of the rest, and even as regarded the Bombay Presidency his observations had been limited to but a few of the many sides of local life there presented to him. But with reference to the reflections that had been cast on what was termed the unthrifty habits of the Indian ryots, he would like to say that, so far as the ryots of the Southern Mahratta Country and the Canarese marches of Western India were concerned, they did not in the least correspond with his own experience. They were a most thrifty people, most industrious, and most enduring, while their lavish expenditure on funerals, marriages, and other ceremonial observances, was determined by their religious beliefs; and though it might waste their resources, it promoted their happiness, and would be continued so long as they remained in the faith of their forefathers, by which their lives had been regulated for nearly 5,000 years. He might say, also, that he thought Sir William Wedderburn had made out a strong case for a carefully limited experimental trial of his proposals for the relief of the almost universal indebtedness of the Indian ryots. He appreciated all the difficultles besetting the attempt. These simple people would never distinguish between the agricultural banks Sir William wished to establish and the Government. In India every man who wore a shoulder-belt and brass plate was identified with the Government; and Sir William Wedderburn would remember how, on the eve of the Mutiny, in 1857, an enterprising native swindler went all about the Southern Mahratta Country levying improvised taxes in the name of the Government, on the sole authority of a label of the Royal Arms of the United Kingdom on an empty Fortnum and Mason's, or Crosse and Blackwell's pickle bottle, in which he collected the contributions of his easy dupes. The proposed banks seemed to him somewhat unsuited to the genius of the people, and this was the fundamental difficulty of our position in India, that we were a foreign Government there, and that the ideas and institutions of our modern Western system of competitive civilisation, to which we owed our prosperity and great international position in the world, were in direct, and inherently antithetical, opposition to the whole social and economic constitution of a country still organised, throughout its greater part, on the basis of the ancient Eastern co-operative system of civilisation. Under that system, as originally developed, the law of landed tenure wae associated with the benignant provision familiar to us all under its Biblical designation of the "Law of Jubilee," by which no ryot's debt could run more than fifty years [Leviticus xxv. and xxvii.]. He did not pretend to fully understand such intricate economic questions, and did not know whether the suggestion was a sound one or not, but in treating of the picturesque aspects of Indian village life he had more than once indicated that some such conditions as those of this law of Jubilee might be introduced by us for the relief of the apparently hopelessly encumbered ryots of India. He thought also that Sir William Wedderburn had made out a strong case of the most exasperating neglect of his benevolent proposals; but this indictment lay, in his opinion, less against Lord Kimberley than the usual "cussedness" of Providence; and he felt sure that Sir William Wedderburn's present paper, and the discussion that had taken place on it, when published in the Society's *Journal*, would lead to a revival of official interest in the subject, and probably to its being once more referred by the Government of India to the India-office. At any rate, the Indian Section were under deep obligation to Sir William Wedderburn for his interesting paper; and the earnest sympathy it evinced with the people of India must have been gratifying to all present, and would secure him the unanimous and hearty thanks of the meeting. He desired also to acknowledge the obligation of the Indian Section to Mr. Samuel Smith for presiding on the occasion. Occupying the onerous and honourable public position he did, it was most kind of him to give up three ungrudged hours of his time to the service of the Society.

Mr. H. M. HYNDMAN denied that the Credit Foncier in France, or similar institutions in Germany, Austria, Italy, or elsewhere, had been of any benefit to the peasantry, as alleged by the reader of the paper. On the contrary, the Agricultural Commissions in France showed that facilities for borrowing were dangerous to the small landowners. The Imperial Commission in Germany, of which Professor Nasse was President, showed the condition of small owners in Baden-Baden and Alsace, and that of which Senator Jacini was President, the state of things in Lombardy. So far from having benefited the peasantry, the tendency had been quite the reverse. The creation of land banks in India of the kind advocated by Sir William would, he feared, increase the domination of the towns over the country, and slowly drain away the substance of the peasantry still more. If, by the establishment of a

bank, the rate of interest now charged by the money-lender was cut down, some good would be done; but he should be very sorry to see the plan introduced into India, as it would have other effects, which would be injurious.

The CHAIRMAN thought the paper must have impressed everyone, as it dealt with a question of vital importance to India. The most pressing question was the poverty of the peasantry and their indebtedness. It was true there might be many difficulties in the way of remedying this, but he thought the lines upon which Sir William Wedderburn had advocated relief were, in the main, sound, though whether they could be carried out to the extent suggested was not in his power to say. He certainly thought the experiment ought to be tried. It was to be extremely regretted that, from some fault or other, for ten years the valuable suggestion which had been made should, through the action of the home Government, have remained a dead-letter. He hoped the discussion that day would do something towards reviving interest in the question, and that they would be able to press the Government to remove any impediments which they might have placed in the way of the authorities in India. It struck him that the Indian Government was far more competent to judge of this matter than the English Government. In conclusion, he begged to propose a hearty vote of thanks to the reader of the paper.

Sir WILLIAM WEDDERBURN, in reply, said that, in his opinion, the Poona Committee had given satisfactory answers to all the objections raised by the India-office. The correspondence would be found in the Blue-book. The promoters, however, did not attach much importance to a victory in this academic discussion. What they wanted to do was to try a practical experiment. In India things seldom turned out as was expected even by the most experienced officials. For example, it was believed that the financial difficulties of the ryot would be best relieved by an Insolvency Act, and accordingly insolvency clauses were introduced into the Deccan Relief Act. But not a single ryot would accept the benefit of its provisions. Two or three ryots were declared insolvent by the court, but it was done against their tears and protestations. They said they would be disgracing their ancestors if they did not pay their debts, as religion required, and that they were being ruined both in this world and in the next. To go on arguing about matters of detail was waste of time. The thing was to set the bank going, when the real difficulties and the best remedies would come to light. He was grateful to the gentlemen who had taken part in the discussion. Sir C. Bernard had said the promoters proposed the experiment on too large a scale. To that he would reply that this objection had never been taken before. Also they were quite willing that the experiment should be tried on a smaller scale, say in a group of villages, provided a real genuine experiment was made. Then it was objected that the money-lenders would not come into the scheme; but the fact was the money-lenders had already agreed to co-operate, for they saw that as shareholders in the bank it would be more profitable for them, lending borrowed funds instead of their own capital. It was only when the local money-lenders had agreed that the deputation of bankers, money-lenders, and ryots waited on Sir James Fergusson. The scheme was mainly decreed by experienced native pensioned officers, revenue and judicial, who were thorough men of business, who had themselves carried on the administration of the country and knew the needs of the people. The interminable correspondence, lasting over five years, had wearied out the promoters. The chairman, a leading banker of Poona, had died during the negotiations, and others had got disgusted by the obstruction and delay. That was how the scheme was defeated. With regard to the action of the French Credit Foncier, to which Mr. Hyndman referred, it would of course be necessary to guard against the tyranny of large capitalists as against the tyranny of small capitalists; but, in this particular case, it was proposed to place the management of the bank in the hands of a class of men who had the complete confidence of their fellow citizens. He had purposely omitted reference to the Deccan Relief Act, because it was a very controversial question. Also although the Act did something to disarm the creditor, it also struck at the credit of the ryot. He agreed with Mr. Rogers, that the shortening of the term of limitation had done great mischief to the ryot.

The vote of thanks having been unanimously agreed to, the meeting terminated.

TWENTIETH ORDINARY MEETING.

Wednesday, May 11, 1892; Prof. WILLIAM CHANDLER ROBERTS-AUSTEN, C.B., F.R.S., Member of the Council, in the chair.

The following candidates were proposed for election as members of the Society:—

Castle, Sydney C. C., 40, Chancery-lane, W.C.
Gubbins, John Harington, British Legation, Tokio, Japan, and Oriental Club, Hanover-square, W.
Smith, Sir Donald A., K.C.M.G., LL.D., Montreal, Canada.
Woolf, M., 16, Greville-place, N.W.
Young, Herbert Edward, White Hart-street, High Wycombe.

The following candidates were balloted for and duly elected members of the Society:—

Collins, Ernest, The Gables, Wedderburn-road, Hampstead, N.W.
Deverell, Frederick Harold, The Custom-house, E.C.
Dowling, Dennis John, Bromley, Kent.
Elworthy, Herbert S., care of William Watson and Co., Bombay, India.
Fowler, Alexander Farquharson, Highfield, Ashton, Preston, Lancashire.
Gray, Robert, Glenclune, Port Glasgow.
Grinlinton, J. J., care of Messrs. Darley and Butler, Billiter-square-buildings, E.C., and Colombo, Ceylon.
Grover, Colonel George Edward, R.E., British Section, World's Columbian Exposition, Chicago, U.S.A., and United Service Club, S.W.
Gwynne-Griffith, J. St. A. Mansel, Hendre-Owen, Bedford-park, Chiswick.
Hutchinson, Surg.-General Robert F., M.D., 35, Clanricarde-gardens, W.
Ismay, Thomas Henry, J.P., D.L., Dawpool, Birkenhead.
Jones, Julius Marris Wilson, 309, Kennington-road, S.E.
Kempster, William Henry, M.D., Oak-house, Battersea, S.W.
Osborne, Major-Gen. W., United Service Club, S.W.
Rollit, Sir Albert Kaye, M.P., LL.D., Dunster-house, Mark-lane, E.C., and Cottingham, East Yorks.
Sandell, Henry William Adrian, M.R.C.S., L.R.C.P., Leighton Buzzard, Bedfordshire.
Saubergue, Arthur de, 3, Victoria-street, S.W., and Barbadoes, West Indies.
Sherwell, John William, Saddlers'-hall, 141, Cheapside, E.C.
Tonks, J. William, Vittoria-street, Birmingham.

The paper read was—

THE USES AND APPLICATIONS OF ALUMINIUM.

By G. L. Addenbrooke.

The utility of a metal in the arts is governed by its physical properties, and the price at which it can be produced in an available form. I propose, therefore, as a commencement, to deal with both of these aspects of the question this evening, in order that a fairly correct basis may be arrived at on which to estimate the uses to which aluminium is applicable; and, in what I say, it must be understood that I refer generally to aluminium itself, or to aluminium alloyed with a few per cent. of other metals, unless it is mentioned to the contrary, and not to aluminium bronzes, or bronzes consisting chiefly of copper alloyed with a few per cent. of aluminium.

Let us commence with the cost of the metal, as that so largely determines its sphere of usefulness. Just three years ago, in this room, Mr. William Anderson described the Deville-Castner process, which had then just been put in operation by the Aluminium Company of Oldbury, near Birmingham. It was then stated that it was proposed to manufacture aluminium at 20s. per lb., or at about one-third of what its price had been previously, and still leave a satisfactory commercial profit. These anticipations would have been duly realized but for the contemporaneous perfection of the electrolytic methods of reducing aluminium, which, being brought into use on a large scale, have resulted in an enormous reduction in the cost of production, and this has constantly reduced the market price of aluminium in a manner which is probably without parallel in the industrial history of metals. Starting three years ago, as has been mentioned, at 20s. per lb., the price of aluminium quickly fell to 15s., then to 12s., next to 8s. and even 6s. It was thought, about a year ago, that the climax, for the time being at any rate, had been reached, when the Pittsburg Reduction Company of Pittsburg, Pa., announced that they were prepared to supply aluminium at a dollar, or 4s. 2d. per lb. But the competition chiefly of the Aluminium Industry Company of Neuhausen, Switzerland, whose works are operated by water power and are on a large scale, has led to still further reductions, and at present, in considerable quantities, aluminium of 99 per cent. guaranteed purity is obtainable at 2s. or even less per lb.

On anything like the present output this price is hardly a remunerative one for the companies engaged in production; and it seems to me that it is improbable that there will be much greater reduction at present. On the other hand, I do not think the price is likely to rise very much again, because a larger consumption of the metal would make this rate a paying one, which would lead to increased output. This, then, is the cost basis on which we have to estimate the openings for aluminium during the next year or two, a cost, bulk for bulk, not greatly exceeding that of copper, for at present the cost of copper is about 5d. per lb., and, since it is $3\frac{1}{2}$ times as heavy as aluminium, the latter, at 2s. per lb., would equal copper a $\frac{24 \times 2}{7}$ = say 7d. per lb., or a relative cost for equal quantities of as 5 for copper is to 7 for aluminium.

It may be interesting to outline briefly the processes by which these astonishing results have been obtained, particularly as finality has by no means yet been reached; and should the uses of aluminium warrant a largely increased output in the future, considerably better economical results could be attained.

As usual, success has been achieved by the labours of many minds, but there are two patented processes under which most of the aluminium at present made is being manufactured. The first is that of Mr. Hall, of Pittsburg, Pa., whose patents are owned in America by the Metal Reduction Company of Pittsburg, and in England by the Metal Reduction Syndicate of Patricroft, near Manchester. The second is that of M. Heroult, a young French engineer. This latter process is controlled by the Société Electro-Metallurgique of Troyes (Isere), in France, and by the Aluminium Industry Company of Neuhausen, Switzerland, at which latter works the largest plant in the world for the reduction of aluminium and its subsequent working is situated.

Although, however, two in name, there is, in fact, very little difference between these two processes, so far as the details have been made known, and therefore, for my purpose this evening, one description will answer for both.

In both cases the oxide of aluminium, or alumina, $Al_2 O_3$, is the material from which the metal is reduced. This is dissolved in a fused flux, consisting of fluorides of aluminium and sodium, which simply serves as a vehicle to carry the alumina. The furnace for effecting the operation is made in the form of an iron-cased box, which is thickly lined with carbon, having a cavity in the centre into which the materials for reduction are introduced. Two or more of these furnaces are placed in series, and one pole of the dynamo is connected to the carbon lining of the first, forming the kathode. A large block of carbon carried on an adjustable support, and arranged so that it can be dipped into the central cavity of the furnace, forms the anode, from it connection is made to the lining of the second furnace, and from the carbon anode of the second furnace, if there are two, the main passes back to the other terminal of the dynamo.

In starting the plant, the carbons are brought well down in the furnaces, and the current turned on. At first considerable resistance is offered, but as the materials in the furnaces get warm this decreases, and the carbon anode can be raised somewhat. Decomposition takes place at about a full red heat, the alumina is resolved into its elements, the oxygen partly unites with the carbon, and is given off as carbonic oxide, and partly escapes free, while the aluminium sinks to the bottom, and gradually accumulates. When a sufficient quantity has collected, it is tapped off and run into moulds without interrupting the process of reduction, which is thus continuous. As the aluminum in the furnace is decomposed, the resistance rises, as the workman can see by watching the ammeter, and this is an indication to him to add more alumina.

It will thus be seen that the process is a pretty simple one. First, we have the dynamos, which must be driven by steam or water power, and which, as they are operated continuously, can be worked to the best advantage. The load is fairly even, and therefore the wear and tear on this part of the plant should be small. Then we have the furnaces, which are not expensive, and will only require the carbon lining and anodes renewed occasionally. Lastly, the flux, acting simply as a carrying vehicle, needs only small additions from time to time. The four great items in the cost of production of aluminium are, therefore, the cost of the electric energy, of the alumina required, wages and superintendence, and depreciation and interest on capital employed.

Now, in the Hall process, it is found that 22 electric horse-power flowing through the bath, at a potential of 8 to 10 volts, for one hour, is what is required to reduce 1 lb. of aluminium, and this can easily be produced by the combustion of half a hundred weight of coal, which, at 10s. per ton, means a cost of 3d.

As to the alumina, I am informed by the Metal Reduction Syndicate that the anhydrous alumina which they use, and find most suitable, on account of its freedom from impurities, costs £30 per ton, and yields about 50 per cent. of its weight in aluminium. The cost, therefore, of the raw material is at present about 6d. per lb. for the aluminium contained.

The cost of the pound of aluminium then totals up to 2s. 9d. per lb. for the aluminium extracted, unless indeed water power is employed, as at Neuhausen, where the first item is of course considerably reduced.

Coming now to the capital required, a horse-power of plant, working for 24 hours, produces, in practice, about 1 lb. of aluminium. Supposing the plant works 300 days a-year, we

have 300 lbs. of aluminium as the product of an indicated horse-power of plant working for a year. Now, such a plant as this could easily be erected complete, including buildings and all accessories, for £30 per indicated horse-power available; and supposing we take upkeep at 10 per cent., and interest and profit at 10 per cent., this represents £6 per annum to be spread over 300 lbs. of aluminium, or 5d. per lb., which is a very liberal estimate, and may well include the cost of carbons and fluxes. For these three items then we have a total of 1s. 2d. per lb. Finally, come labour, superintendence, and administration expenses. These so much depend on the output, which at present is small, that I shall not attempt to estimate them. It will be sufficient for my purpose if I have shown that the present price of aluminium ingots, say 2s. per lb., cannot leave much margin of profit on the present rates of output, which are about as follows:—The Aluminium Industry Company, 1,000 lbs. per diem; the Pittsburg Reduction Company, 600 lbs. per diem; the Metal Reduction Syndicate, of Manchester, 300 lbs. per diem; Cowles Company, 600-700 lbs. in alloys. At the same time it is sufficiently near the remunerative level to prevent any great advance, except by a reduction of output, or some agreement amongst manufacturers.

To get further cheapness, a larger demand and production are needed, which must come within a moderate time, when we may safely calculate on aluminium comparing at any rate on equal terms with copper as to price for equal bulks; but from what I have shown I think it is pretty clear that we cannot look for much reduction on the price I have named in the immediate future. Improvements will certainly take place in the processes of manufacture, and I feel very hopeful of them, but they will probably be in details rather than in any fundamental alteration of the present electrolytic process of reduction, and will chiefly take the form of improvements in the methods of obtaining pure alumina or some other salt of aluminium, and in the method of operating the furnaces, in which at present only about 25 per cent. of the energy is utilised for reduction directly, the rest being absorbed in heating the materials. Electric heating has so far been, I believe, found preferable to direct heating, but I cannot help thinking that, at any rate where steam engines are employed, further experience will lead to improved forms of apparatus being devised, which will admit of the heat required being applied directly and more economically than through the intermediation of a steam-engine, which, as a heat producer, is so very inefficient.

To pursue these lines of thought further would be speculative, whereas my object this evening is of a more practical nature; therefore, having settled on an approximate price at which aluminium will be obtainable for present use, it remains to be seen what field this price, coupled with its peculiar physical and mechanical properties, will enable it occupy.

Within the last ten years the quality of metal manufactured has been very much improved, and the larger quantities in which it has been dealt with have given better opportunities of estimating accurately its nature than was possible before. Most of the metal made is now of over 99 per cent. purity, and the reduction in the amounts of iron and silicon contained in it, which are the chief impurities, has altered and improved its working qualities considerably, when it has to be rolled, spun, and drawn.

To show exactly what its properties are, I have here a cast bar of pure metal, about ½ in. wide, ⅜ in. thick, and 1 ft. long. Taking the ends of that in my hands, you will see that I can bend it double, bringing it into the form of a rather elongated **O**, without breaking; that is about the limit of what it will stand. As regards hardness, it is rather softer than copper, and in the lathe, or under the file, behaves in much the same way, having a strong tendency to pull, and tear, and clog the tools. Like copper, too, it is softened by being plunged hot in cold water, and hardened by being cooled slowly.

Clearly, in this state, it is not very suitable for castings, and, just as zinc and tin are added to copper to improve its qualities, so some similar additions must be made to aluminium, if it is to be as useful in this form as its other qualities lead us to anticipate.

In the endeavour to improve the qualities of aluminium, without detracting appreciably from its characteristic properties of lightness and incorrodibility, I have gone over some old ground, and perhaps entered a little new, and a few notes on the results of additions of other metals to aluminium may be interesting, as the literature on this subject is rather fragmentary and incomplete, and early experiments were mostly performed with impure metal.

To begin with, the pure metal does not cast quite so well, nor is it as hard or strong as when it contains 2 to 3 per cent. of silicon,

though its malleability is decreased, and it has a scratchy sandy feel.

The addition of iron appears to be simply detrimental, leading to porous castings, while the metal is of a rotten nature.

Copper gives much better results; it hardens the metal considerably, when added up to 5 or 6 per cent., after this brittleness is produced.

My experience with copper, however, is that the alloy does not stand re-melting well, but soon becomes porous; on the other hand, until it has been several times melted, and allowed to stand, scum is apt to form, and mingle with the metal, producing bad marks in the casting. The metal also still pulls in the lathe. Silver alloys with aluminium very well, but its cost puts it out of court for most purposes.

Zinc hardens aluminium, and also toughens it when added to the extent of 3 or 4 per cent., but the resulting metal is difficult to turn, and the alloy is not a very clean one; it does not stand re-melting well.

The addition of tin appears primarily to have two actions—up to 3 or 4 per cent. it makes the aluminium short, but improves its turning qualities; if 10 per cent. is added, the bar is at first as pliable as the pure metal, and of about the same strength, but if this metal is once or twice re-melted it soon becomes crystalline.

Nickel has much the same effect; when added to copper, it however produces a closer grain, though still leaving a bad surface under the tool.

Though the qualities of aluminium therefore are improved in some respects by the addition of alloys, none of them seem to produce alone quite what is wanted.

In combination, however, better results are obtainable, and I have here some specimens made by the Phœnix Engineering Company. The exact composition of these I am not at liberty to disclose at present, but it will be seen that the metal is both whiter and much harder than aluminium, while it can be turned with practically the same facility as brass, leaving as good a surface. A good example of the alloy will have a rigidity slightly superior to ordinary cast brass, though it cannot be bent to the same extent; however, it is still fairly malleable, and bears considerable extension under the hammer. As with so many other alloys, the best results are obtained after the metal has gone through a certain amount of mixing and re-melting; afterwards frequent re-melting renders it more brittle, and is apt to produce porosity. This, in fact, constitutes the chief difficulty in casting aluminium, and it is aggravated by the fact that most of the objects hitherto made in aluminium are small, while, owing to the lightness of the metal, higher heads are needed than for brass or iron; there is therefore necessarily a good deal of re-melting if metal is not to be put aside. This difficulty is, however, one which practice and the use of aluminium for an increasing number of objects will diminish.

To illustrate what can be done with this alloy, I have here a dumpy level made from it, including all the screws and working parts. Further, I have camera screws and nuts, tripod heads, and a portable galvanometer, while Mr. Dallmeyer has been kind enough to send down examples of his lenses, particularly his new ones, all the parts of which, except the tubes, have been made of this alloy. It will be noticed that satisfactory screws can be cut in the metal. I have here also a specimen of a small resistance box, of which the top is made of it, and which appears to answer very well.

The alloy will also be useful, I think, for the frames of light motors, and for some of the working parts, for parts of portable microscopes and telescopes, range finders, heleographs, projectors, arc lamps, field telegraph apparatus, stands for portable lamps, and for a considerable number of other purposes where a fair degree of strength and rigidity is needed, combined with lightness and incorrodibility.

Before passing on from the consideration of alloys, I must mention the beautiful one of aluminium and gold, containing, I believe, about 23 per cent. of the former metal, which has been discovered by Professor Roberts-Austen, and which he has been kind enough to bring to-night. In structure it is crystalline, but the interesting point about it is its beautiful rose-pink colour, which is quite different from anything that has been observed in metal before.

Of alloys with aluminium in general, it may be said that they decrease its malleability, and that, for metal which has to be rolled or drawn, it is usually expedient to employ the pure metal, in fact the purer the better. I think, however, that as the handling of the metal is better known, some of these alloys may prove useful, and provide us with harder sheets, and wires of higher breaking strain than can be obtained from aluminium itself.

Passing now from cast aluminium to rolled

and drawn. There are on the table some 5 lb. ingots cast in iron moulds, such as are used for rolling from. These can be rolled right down into sheets of any thickness cold and without annealing, of which there are several specimens before you, ranging from the ordinary grades down to one which I have, and which is only 1-1000th of an inch thick; while, to proceed further, foil can be beaten out into leaves, the thickness of which is about 1-40,000th of an inch. This leaf has almost entirely superceded silver for gilding on account of its permanence, as a good instance of which I can show you a book of leaf which was made in 1868, and has been in London since. You will perceive that it is as bright as the day it was made.

Sheets of aluminium cold rolled become very hard and quite springy, in fact their rigidity is greater than that of ordinary brass sheets. They will still stand a fair amount of bending, and can quickly be made quite soft by annealing at a temperature of about 400°. It is evident that such sheets are applicable to a number of purposes in the flat. For instance, they have been used for making canoes and the hulls of steam launches, or for parts of photographic cameras. Sheaths for holding photograph films, and a number of the parts of portable instruments, are also readily made from aluminium sheet, and it will also, I think, have a future for ornamental work for electroliers and gas brackets, especially in conjunction with iron work, with which it forms an excellent contrast; but its greatest value lies in forming the substratum, so to speak, for stamping and spinning.

Of the various useful articles which will be made of aluminium in the immediate future, it is safe to say that a large proportion will be stamped or spun, for aluminium lends itself particularly well to this work, and anything that can be so made in other metals can be carried out in aluminium. It has, like other metals, a few peculiarities of its own which require to be mastered, but when this is done, we have a metal which is as tractable in the hands of the workman as silver. As instances, there are on the table some fine stampings of a couchant lion and examples of buttons, also forks, the backs of brushes, &c., which show how much can be accomplished, and what a nice effect the work has.

Of spinnings, Messrs. Still and Co. have been kind enough to send some fine examples: there is, for instance, a stethoscope entirely spun up, including the tube and both ends, from a circular plate, such as I have here; a more perfect specimen of what can be done with a metal, and what it will stand, it would, I think, be difficult to conceive—though so light, it is yet very rigid. There are also examples of surgical specula; an ewer and basin; and, lastly, some helmets for firemen or military purposes; these, Messrs. Still and Co. assure me, they consider as strong and stiff as ordinary brass, of which there is also an example, that its weight may be compared with those in aluminium.

Then I have here an example of the aluminium flask, of which so much has been said lately in connection with the German army; it will be observed how light and strong it is. For comparison, there is another somewhat similar one of English manufacture. The uses of aluminium for cooking utensils, probably for cartridge cases, should also be noted here.

Lastly, there are some very interesting plaques and picture frames, the work of the Scovil Company of New York, which are an interesting example of scratch brush work.

Turning now to a slightly different field, here are examples of tubes. Some provided by the Mannesmann Company, as examples of their power, are 12 or 14 feet long, and of excellent quality. For the remainder I am indebted to the Phœnix Engineering Company. All these tubes, I need hardly say, are solid drawn; and it will be noted what excellent examples of workmanship they are. For telescopes, and wherever lightness is essential, they must supersede brass or German silver. Whether they will answer for bicycles still remains a moot point. I have tested two sets of tubes of the same dimensions—one of steel and the other of aluminium—in the following way. The tubes were supported in **V** groves a foot apart, and a lever was brought down on the centre of the tubes between the supports, a pad and narrow ring being used to secure a fairly even pressure. The lever was then adjusted, and it was found that the aluminium tubes stood about half the strain of the steel tubes, though their collapse was a little more complete on passing the critical point. As an instance, an aluminium tube one inch in diameter and forty mils. thick stood a strain of 200 lbs. applied in this way. This, I think, must be considered very satisfactory.

Of the applicability of aluminium to opera and field-glasses it is needless to speak, but there is an example on the table of a glass

made in 1864, which has been in constant use since. In 1870 the wheel of a carriage passed over it, but it was afterwards straightened out and made usable. It has made two voyages across the Atlantic, two across the Pacific, and has had other shorter experiences of the sea air, besides lying on one occasion for some time in salt water; this disposes of the idea that aluminium is readily spoiled by contact with sea air. For my part, I have kept strips of aluminium for two or three weeks in salt water, and have noted very little effect.

I might continue this somewhat discursive paper further, and it is obvious that I have only enumerated a few of the uses to which aluminium can be put, but I have rather relied on showing from the examples before you that aluminium is an easily workable metal, and can be worked into almost any form which metals, such as copper, brass, and silver, are capable of assuming, having once grasped which, each in his own sphere, can find uses to which it adapts itself. At its present price, it can be classed as eminently a useful metal, and the lower the price becomes, the wider will be its sphere of utility.

There is, further, one goal towards which aluminium workers will look forward, and the attainment of which it is not unreasonable to expect in the future. At present, the price of aluminium is about four times that of pure copper for equal weights, and its output is little more than a ton a day for the whole world. In the improvements in the process of reduction, and an output of some thousands of tons per annum, is it looking too far a-head to anticipate that the price will be reduced to that of copper, when aluminium, with its conductivity of 200 per cent. that of copper—weight for weight—would, in a large measure, replace the latter metal for mains for electric lighting.

In what I have said nothing has been mentioned about solder. I have here an example of some joints I have had made, which are fairly satisfactory. Strength of joint is secured, but the process of making it requires a good deal of care, on account of the high melting point of the solder and the difficulty of getting it to flow readily. Still it can be done. Messrs. Balfour and Co. have, however, informed me that they have a solder which they propose to bring out shortly which is a great improvement on previous ones. They have brought some examples of work done with it to-night, from which it will be seen that the joints are quite invisible. I have not yet seen any actual joints in the process of being made, but aluminium workers will await further results with interest.

DISCUSSION.

The CHAIRMAN said Mr. Addenbrooke had referred to the probability that where steam engines were employed further experience would lead to improved forms of apparatus, which would admit of heat being applied directly; but it seemed to him that that was very doubtful if the heat were applied to the carbon, which was the reducing agent, because it required more heat to dissociate aluminium than it did to dissociate the products of the reduction, which he held in this case was carbon anhydride. He held the effect was due to the conbined effect of heat, and the dissociating influence of the tearing electric current. But of course this was a matter for discussion. Mr. Addenbrooke had referred to the interesting alloys of aluminium with other metals, and mentioned some facts which were perfectly new to him, especially that nickel and aluminium appeared to disintegrate spontaneously. There were other cases in which alloys behaved in that peculiar way, but they were very rare. He also referred to the alloys of aluminium with the precious metals, and on one of the series he had carefully worked recently, and found that alloys of aluminium and gold possessed certain pecularities which deserved very careful attention. The melting point of gold was 1045° C.; when alloyed with 10 per cent. of aluminium, the melting point fell about 400°, and the alloy was as white as silver; but on adding another 10 per cent., the melting point rose to 20° above that of gold itself and the alloy was a brilliant purple. By adding further quantities of aluminium, the melting point was again reduced until it came to that of aluminium itself, about 650° C. He believed that was the only case known, free from mercury, in which the melting point was higher than that of the least fusible of the constituents, and pointed to the fact that the union of the two metals must be very peculiar indeed.

Mr. S. G. GORDON said the paper was very interesting, and he regretted that he could not add any information, as he had very little opportunity of doing anything with aluminium except seeing the working of it by the Mannesman process. In that way pure aluminium worked very satisfactorily, as was proved by the spinning, and in other ways. The Mannesman Company had made large quantities of aluminium tubes, and found that as long as the metal was pure there was no difficulty in working it, and it would stand repeated rolling, cold, without injury. It had been mentioned that a small quantity of silicon had a great influence on the casting properties of the metal, and that was a line of research which should be followed up, the alloys which had hitherto been made having usually consisted of a fairly large proportion of other metals.

Mr. B. H. BROUGH said he exhibited, at one of his late Cantor Lectures, a series of mine-surveying instruments, made of aluminium, to show its applicability to such purposes. Of course, lightness in this case was of the utmost importance; and anyone who had to carry surveying instruments through the tortuous passages of a mine, or up the steep sides of a mountain, where every additional ounce became a grievous burden, would appreciate that; but, since then, he had had an opportunity of testing the wearing capacity of these instruments, and did not find them altogether satisfactory. He had used a theodolite as an educational instrument, with a class of about thirty students from the School of Mines, and it did not stand the hard usage it was thus exposed to. The screws stripped, and the wear had been very bad, so that it might be safely asserted that aluminium was unsuited for such instruments where an occasional stress had to be borne; for whenever the metal was bent out of shape it seemed almost impossible to restore its original adjustment. He noticed in that week's number of the German mining journal a note about the Neuhausen Aluminium Works, stating that about 54 per cent. of the daily output was consumed by German steel makers, as an addition to molten steel, with a view to obviating the formation of blow-holes. If that were so, it seemed a very important use, and worth mention in the paper. When the members of the Iron and Steel Institute visited the aluminium works at Pittsburgh, they had presented to them, as a souvenir, a little aluminium box, which was one of the prettiest objects he had ever seen. It consisted of a very tasteful design, and showed very clearly how ornamental workmanship in this metal could be made.

Mr. C. W. PARKER (Messrs. Balfour and Co.) said he was not at liberty to go into much detail on this matter, but there was no doubt that this metal was very useful, and his firm had just produced a very reliable solder, the best yet tried, which would be a great service in many ways. One great point about it was that it did not oxidise, and, further, it amalgamated with the metal in the soldering. On one of the pieces he had sent, it had been hammered, and though the metal had bent the joint had not given way. The solder was composed of aluminium and tin; was patented, and instructions for using it would be given to licensees.

Mr. WALTER T. REID said the question of soldering seemed to be of great importance. The composition of one had just been published in *Dingler's Journal*, consisting of 50 cadmium, 20 zinc, and 30 tin. Like other aluminum solders, it was said to be better than the metal itself, and to do everything required of it. He had made some experiments in soldering aluminium, and found that one of the chief points was a flux to cover the joint, as you then had a much better chance of getting a sound joint. Probably the surface of the metal became covered with a thin film of alumina, which prevented the solder flowing. He had also made a few experiments with aluminium as pure as it could be obtained, and had one or two failures to record. It did not answer his expectations, perhaps because they were too high. He found it would not stand sea water, nor even a solution of pure chloride of sodium; the metal was corroded in a very peculiar way, almost as if there were impurities in it, but on cutting out the corroded portions, and testing them, he found they were as pure as the bulk of the metal. Another thing he tried it for was cartridge cases; but he found, when subjected to atmospheric influences, either with black powder, or with some of the nitre compounds which fomed the basis of smokeless powders, it was corroded, not perhaps more than brass, but quite enough to interfere with the strength of the metal. It was well known that the pressure of a very small quantity of sodium had a very deleterious effect on this metal. He should like to ask Mr. Addenbrooke if he had any information as to the action of ordinary liquids used for beverages on aluminium. Some time ago, in the German papers, there was some allusion to an alleged case of poisoning through the action of brandy on the metal of one of these flasks, and although not proved, the statement was sufficient to discourage their use.

Mr. PARKER said the solder he referred to required no flux. There was a specimen on the table which had been in a salt bath for some time, and it was not at all oxidised.

Mr. ADDENBROOKE said he thought the Chairman hardly understood his reference to the use of heat; he did not mean to reduce the metal, but simply to bring the bath to a red heat, which was now done by the current itself. In electric heating you had to put coal under the boiler, turn the water into steam, pass it through the engine, and then operate the dynamo, which was an uneconomical mode of producing heat, though of course you had the heat inside the furnace instead of outside, which might help to balance it. With regard to alloys of aluminium with small quantities of other metals, the work he had done had been with aluminium of over 99 per cent. purity, and in ordinary work he had noticed that the addition of ½ per cent. of other metals did not make much difference; you required one or two per cent. before perceiving any effect; but no doubt by testing the breaking strain accurately, you might find there was a difference. It must be remembered that you had, say, ¾ per cent. of impurity to start with, so that it was impossible to say what was due to the added metal, and what to the impurity. Perfectly pure aluminium had not been furnished, and he did not think its electrical resistance had yet been accurately determined. It was tested some time ago, when the metal might have had from 2 to 3 per cent. of impurities, and they knew what a great difference a slight impurity made in the resistance of copper.

The figure usually given was about 56 per cent., but in some samples he had measured he had found 58 per cent. of copper. The mention of the survey instrument introduced a point on which some stress ought to be laid. People talked about aluminium as if it were something quite definite, whereas, for all these instruments, an alloy of some kind ought to be used. If they were made of a suitable alloy he would not say they would have lasted as well as brass, but they would certainly wear better than ordinary aluminium even with a little silicon in it. With regard to the addition of aluminium to steel and bronze, he did intend to refer to it, as it was exceedingly interesting, but he thought the scope of the paper was large enough without going into it. One gentleman said he found he could solder aluminium better with the use of a flux, but the usual methods were without any flux, which was generally found to be a nuisance. He had noticed some discrepancies with regard to the action of salt, but fancied they might be traced to the fact of a rather impure sheet being rolled cold. If that were the case, it disintegrated in laminæ, and the salt got underneath and forced out the metal, forming a sort of exfoliated surface. With a really pure metal, well rolled, there was very little action indeed. He had put some in salt water with various organic matters and left it for weeks, and it was very little acted on. He also put some in a bottle of cider and left it uncorked for many weeks, and there was very little action. Most of the soldering must be done with a blowpipe, but an aluminium bit to work over the surface was a useful addition. The difficulty was that the solder did not flow well. You had to heat the metal up to a certain point, when it was just beginning to disintegrate, apparently before the solder began to take: first it went to a pasty state, and then, on a rise in temperature, it began to flow. He hoped the new solder spoken of would be more successful. The melting point of the solders he had used was nearly that of aluminium, and it was almost impossible to do fine work with it without many failures; you were so apt to melt the sheets. There was a method of autogenous soldering by bringing the two surfaces together, and pouring metal on to them until the edges melted and united together, and then cleaning the metal off; it could also be done by means of electricity, but he had not had much experience of these.

The CHAIRMAN then proposed a vote of thanks to Mr. Addenbrooke, which was carried unanimously.

Miscellaneous.

PRESERVED GINGER.

The marked difference between the Chinese preserved ginger and that from the West Indies has been the subject of inquiry by the authorities at Kew as to whether both articles are really the product of the true ginger plant (*Zingiber officinale*). The evidence—other than that of the root—pointed at one time to the fact that the same plant yielded both commercial articles; subsequent materials, however, indicated that Chinese preserved ginger was the rhizome of *Alpinia Galanga*, while that from the West Indies was from the original *Zingiber officinale*. It would seem, however, that still further research into the matter has restored the origin of Chinese ginger to the same plant as the West Indian.

Of the practice of ginger cultivation and the process of preserving but little is generally known. As ginger is, however, an important article of commerce, both in its dried and preserved conditions, the following notes on the subject from the December number of the *Bulletin of the Botanical Department of Jamaica* may be of interest. The most suitable soil for ginger culture is said to be a well drained clayey loam. The land should be well dug and cleared of weeds. Small pieces or protuberances of the root, one or two inches long, are planted during March or April, four inches deep and nine to twelve inches apart. It is well to cover the land with a moulding of dead leaves, weeds, straw, or litter mixed with manure. In a few months the whole ground will be covered. The flowers appear in September. When the stalks wither in the following January or February, it is time to dig up the roots. When the tubers have arrived at maturity and have put forth stems they are fibrous, but before this takes place, while they are still succulent and the young stalks are not more than five or six inches long, they should be taken up for preserving. Ginger is an exhaustive crop on the soil, and should not be planted in the same ground two consecutive years. The yield per acre is said to be 4,000 lbs. and upwards.

Black ginger of commerce is prepared by washing the root in water, boiling for a quarter of an hour. and then drying in the sun. White ginger, a much superior article, is prepared from the best and soundest roots, by scraping off the outer dark coloured part, and then carefully drying, without boiling.

Preserved ginger is made from the young tubers, which are scalded, washed in cold water, and then peeled; the roots are then covered with a weak syrup, and left for two days. The syrup is then poured off and replaced by a stronger syrup, and this is repeated two or three times until the syrup is thick and the ginger bright and nearly transparent. The following is given as the best method of preparing preserved ginger. Pour boiling water on your ginger, and let it steep for a day and a night, then peel and pare away all discoloured and hard parts Boil a syrup of 1 lb. lump sugar to six pints of water (this is for 12 lbs. of ginger). Put your ginger into a stone jar and pour the thin boiling syrup on it, let this stand for a week or ten days, then draw off the syrup and throw another, exactly the same as the

last, again boiling, over your ginger; let this stand for another week, then throw off the second syrup and drain the ginger well on a hair sieve, return it to the jar, and pour over it the final syrup, made as follows:—12 lbs. loaf sugar to 12 pints boiling water; stir till the sugar is dissolved, for fear it should settle and burn, then boil till it is as thick as good honey, and drops slowly from a silver spoon; now pour boiling water over the ginger and let it stand till cold, when you can put it into the bottles or jars in which it is to remain. Put in the pieces of ginger, first, as close as they will pack, then fill right up to the cork to leave no room for air. The corks should be new and good, not old ones that have been pierced by corkscrews.

Since the above was written, some instructions, similar to the foregoing, on the cultivation and curing of Jamaica ginger, printed for distribution in Trinidad, have appeared in the *Kew Bulletin* for April last, together with a notice of a sample of ginger recently received at Kew from Fiji, where it had been grown and cured, and the reports from experts in London were such as to induce further efforts in Fiji. It is described as "remarkable for its exceedingly fine aroma and peculiar pleasant taste, recalling that of lemon."

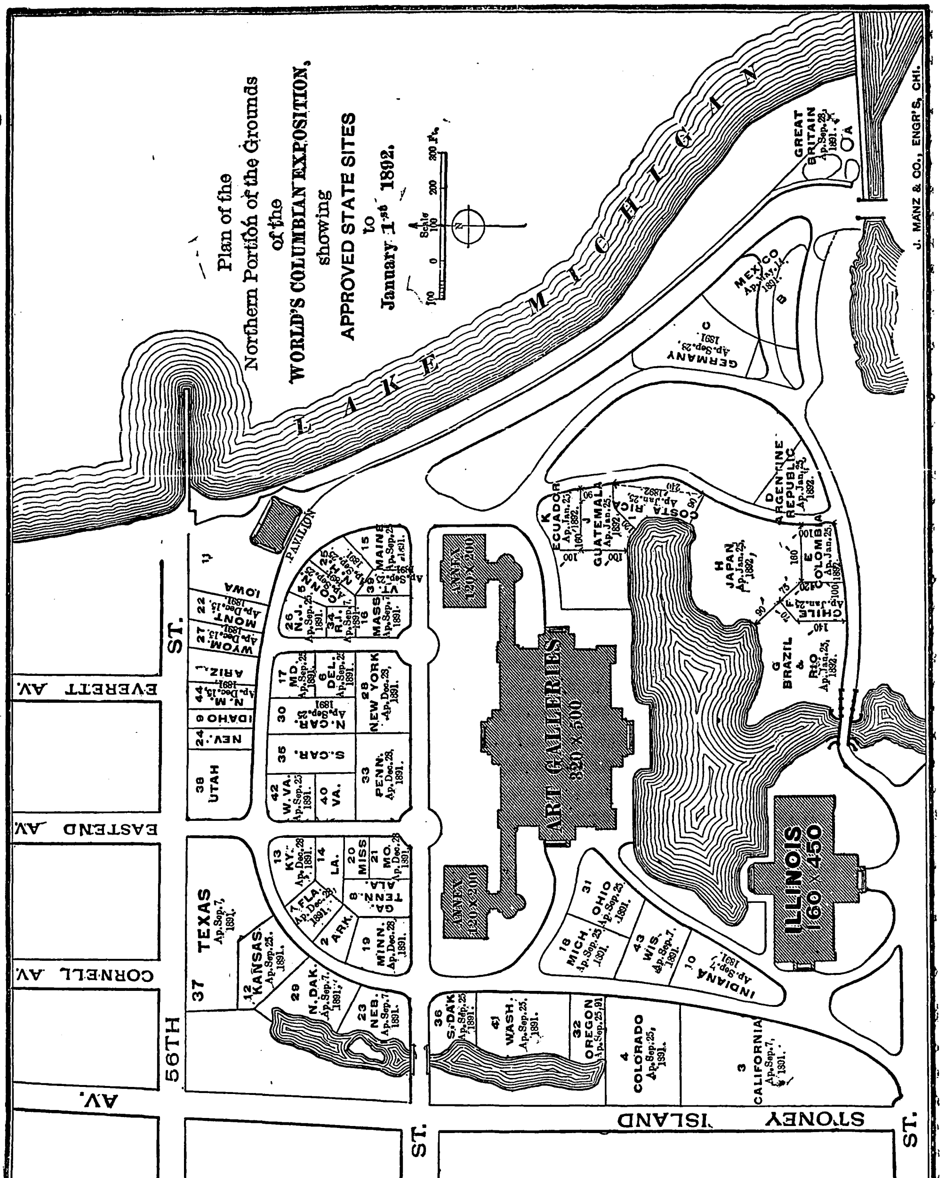
On the subject of the cost of preserving ginger and some of the Jamaica fruits for the English market, a correspondent of the Botanical Department, who, it is said, has been most successful in the operation, writes thus:—"The price charged for all Jamaica preserves is excessive, and defeats its own ends. For instance, preserved ginger, say one shilling for the young ginger, to make 12 lbs., one shilling for the first syrup, and for second, allowing sixpence per lb. for lump preserve sugar, the cost of this being 19s. 9d. per cwt. in England; sixpence for the last syrup. In fact, 6d. per lb. would more than cover the cost of production, apart from labour, and the labour is certainly not greater than that bestowed on most English preserves sold at from 4d. to 6d. per lb. The usual statement as to the cost of the manufacture of ginger is as follows:—It takes 3 lbs. of lump sugar, at 9d. per lb., to make 1 lb. of ginger. Ginger has to be so much pared away, that a shillingsworth makes only a few lbs. The labour is very great, and the profit very small. All these are, I maintain, false statements, and have stood in the way of anything like a large and remunerative trade in Jamaica preserves being established. Fortnum and Mason give it as their opinion that the bar to such a trade is, that Jamaica preserve cannot be sold in London in one shilling glass jars; the British public will buy a small jar of any foreign delicacy at 1s., when they would refuse a larger one at 1s. 6d. This seems a hint worth taking. We ought to popularise our beautiful and delicious preserves by selling them at a small profit, which experience has found again and again results in a much larger gain in the long run. For instance, can any Jamaican assert that guava jelly costs more to make than the best strawberry jam, which is sold in highly ornamental glass jars at 6d. per pound anywhere in England. The guavas grow wild here, and can be had in profusion for the picking. Jamaican vacuum pan sugar makes the jelly in perfection, and can be bought by the bunch at about 2½d. per lb., if I am not mistaken; and, having made both strawberry jam and guava jelly myself, I can confidently assert that the latter is not half the trouble of the former. My sole object in writing this is, that I believe Jamaica is throwing away a large and lucrative trade, which might be hers, if she would remember her own wise saw, "Greedy choke puppy."

These plain words may draw attention to this important subject, not only in the West Indies, but in other tropical countries.

TINPLATE TRADE WITH AMERICA.

Machinery forms an exception to the list of manufactures—rather a long one—in which so far this year but little has been done with the United States. That list includes various metals and metal wares, and also steam-engines, but in general machinery we have done better. From the Board of Trade Returns to hand since our last issue, giving statistics for the first quarter of the year, we notice that the value of machinery and millwork in the first quarters of the three past years rose from £151,994 in 1890, to £224,715 in 1891; and to £236,195 in 1892. To some extent confirmatory of the better business which such figures indicate, is the quarterly return of the United States Consul for Birmingham, also issued since we last went to press. This shows an enormous expansion in the trade in cycles and cycle materials, the advance (in dollars) being indeed as great as from $152,197 last year to $292,911 this year. Cycle exports from the Wolverhampton agency rose also from 5,262 to 14,014. Bedsteads from Birmingham rose from 29,628 to 47,689; and anvils from 19,672 to 21,545. Hardware and steel and iron are down on the year, but the advances above indicated are gratifying, and go to show that, notwithstanding the increasingly severe Protectionist policy of our Transatlantic friends, they are still unable to do without the assistance of British machinery manufacturers. As to the tinplate business with the States this, of course, has fallen off on the year, the quantity we sent being 64,611, or about 34,000 tons less than in the corresponding quarter of 1891. Yet the former quantity may be looked upon as a fair, normal average under the altered conditions brought about by the M'Kinley Tariff, as the average for the three years preceeding was equal to 81,500 tons quarterly. Satisfaction is expressed that the Ways and Means Committee of the United States House of Representatives have reported in favour of the Bill reducing the duty on

tinplates from $2\frac{1}{2}$ cents to 1 cent per pound, and making tinplates duty free after October 1, 1894. The measure is, however, threatened with severe opposition in the Senate, and it is doubtful whether it will become law.—*Implement and Machinery Review.*



CHICAGO EXHIBITION.

The above illustration shows the northern portion of Jackson-park with the allotments made for the buildings of the various states, and the additions which are being made to the Art Gallery.

The plan also shows the positions which have been granted to various foreign countries for the erection of special buildings. The position of the building, which will be erected for the British headquarters, is indicated in the right-hand lower corner of the plan.

Correspondence.

BRADFORD CORPORATION ELECTRICITY SUPPLY.

As I had not an opportunity of replying to one or two statements made by the Chairman, Mr. W. H. Preece, at the termination of the discussion on the above paper last week, may I request the insertion, in the next issue of the *Journal*, of the following remarks:—

1. *As to estimating the output of an electricity station in terms of the number of lamps fixed, of eight c.p. each.* Instead of this being, as the Chairman stated, "the very pith of the question," it is (as named in my remarks at the beginning of the discussion) a very delusive one, often misleading, and one which is purely theoretical, and liable to considerable errors. It may be only part of the output, which (with a "continuous" current at least) may be utilised for lighting purposes; and even that is liable to use in different proportions in several kinds of lamps, which again may vary according to their make. Moreover it is well known how difficult it is to ascertain the actual number of lamps fixed· With a Corporation, who are forbidden to have anything to do with the supply, or with the fitting up of the lamps of the consumers, it becomes, therefore, little more than matter of guesswork, as to how many lamps are actually fixed.

But the principal argument against this mode of estimating the supply is, that it does *not* comply with the terms in which, in the various Parliamentary Electric Lighting Provisional Orders, it is enacted, that the supply is to be estimated. In the earlier Orders of 1883 (of which that of Bradford is one), it is termed a supply of electricity—and each customer is to state, in his application, the maximum rate of current required to be supplied. In the later Orders, 1890, and after, the supply is termed one of electrical energy; and the application must be for the maximum rate at which the electrical power is to be supplied. In all cases the reply should be in "ampères," and certainly not in lamps; for the Legislature certainly contemplated the electrical supply in its fullest application, and not merely as limited to lighting purposes.

2nd. *As to the relative value, in their respective applications, of "continuous" and of "alternating" currents.* After stating, that the Frankfort Exhibition had shown, that the latter form of current was capable of all the applications of the former class, the Chairman adds, "it only required the introduction of a transformer to convert the alternating current into a continuous form." Surely this is very suggestive of the famous discussion on the respective merits of "Black" and of "White" (colours). "But black isn't white," says A; "Yes it is," replies B, "provided you paint it white."

It is not, however, necessary to wait until the year 1891, and the Frankfort Exhibition, to behold the wondrous transformation. For, in 1853, Mr. F. H. Holmes (the designer, subsequently, of the "Holmes" machine for our Trinity House), in Paris, under the auspices of the Société Générale de l'Electricité, transformed, by means of a complicated commutator, the output of several large alternating machines, of eight magnets each, into a continuous-direction current.

One, if nor more, of these machines has been working ever since, under the name of the "Alliance" machine, at the lighthouse of La Hève, near Hâvre—the commutator, however, has been dispensed with.

It is singular, too, how many times, of late years, our expectations have been raised (apparently in vain, as far as actual industrial application at least is concerned) respecting the more extended application of the "alternating" current; and more especially as regards the transmission of motive power.

In the interests of electrical science, and of its applications, it is sincerely to be hoped that these expectations may soon be realised; and by no one would these realisations be more warmly welcomed than by the writer.

JAMES N. SHOOLBRED.

General Notes.

CHICAGO EXHIBITION.—M. Krantz, a member of the Chamber of Deputies, has been appointed French Commissioner-General to the World's Fair at Chicago.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at Eight o'clock:—

MAY 18.—Captain W. de W. ABNEY, C.B., F.R.S., "Colour Blindness." R. BRUDENELL CARTER, F.R.C.S., will preside.

MAY 25.—F. E. IVES, "Researches in Photochromy."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

MAY 19.—JERVOISE ATHELSTANE BAINES, I.C.S., Chief Census Commissioner for India, "The Administration of the Imperial Census of 1891 in India." Sir CHARLES BERNARD, K.C.S.I., will preside.

FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at Eight o'clock:—

MAY 24.—Colonel HOWARD VINCENT, C.B., M.P., "The Extension of Colonial Trade." The Hon. JAMES MUNRO, Agent-General for Victoria, will preside.

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock:—

MAY 17.—WILLIAM SIMPSON, R.I., "Mud as a Material for Architecture in Persia and the East." General ROBERT MACLAGAN will preside.

MAY 31.—WILLIAM DE MORGAN, "Lustre Ware."

CANTOR LECTURES.

Monday evenings, at Eight o'clock:—

Professor PERCY F. FRANKLAND, Ph.D., B.Sc., F.R.S., "Recent Bacteriological and Chemical Research in connection with the Fermentation Industries." Four Lectures.

LECTURE III.—MAY 16.—Practical results of recent investigations—Hansen—Alcoholic fermentation with and without oxygen—Carbohydrates fermentable by yeasts—Artificial sugars in their relationship to yeasts—Fermentations of milk.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 16...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Dr. Percy F. Frankland, "Recent Bacteriological and Chemical Research in connection with the Fermentation Industries." (Lecture III.)

Institute of Chemistry, Burlington-house, W., 3 p.m. Conference on "The Present Regulations with respect to the Admission of Fellows and Associates to the Institute."

British Architects, 9, Conduit-street, W., 8 p.m. Mr. W. H. Preece, "The Art of Internal Illumination of Buildings by Electricity."

Victoria Institute, 8, Adelphi-terrace, W.C., 8 p.m. Sir W. Dawson and Rev. J. Mells, "Primitive Man."

TUESDAY, MAY 17...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr. William Simpson, "Mud, a Material for Architecture in Persia and the East."

Royal Institution, Albemarle-street, W., 3 p.m. Mr. F. E. Ives, "Photography in the Colours of Nature." (Lecture II.)

Civil Engineers, 25, Great George street, S.W., 8 p.m. 1. Discussion on Mr. A. P. Trotter's paper, "The Distribution and Measurement of Illumination." 2. Professor W. C. Roberts-Austen, "The Measurement of High Temperatures."

Statistical, School of Mines, Jermyn-street, S.W., 7¾ p.m. Mr. J. S. Jeans, "The Recent Movement of Labour in Different Countries in Reference to Wages, Hours of Work, and Efficiency."

Pathological, 20, Hanover-square, W., 8½ p.m. Annual Meeting.

Asiatic, 22, Albemarle-street, W., 4 p.m. Annual Meeting.

Zoological, 3, Hanover-square, W., 8½ p.m.

WEDNESDAY, MAY 18...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Captain W. De W. Abney, "Colour Blindness."

Meteorological, 25, Great George-street, S.W., 7 p.m. 1. Mr. G. M. Whipple, "Results of a comparison of Richard Anémo-Cinémographe with the standard Beckley Anemograph at the Kew Observatory." 2. Mr. E. J. Lowe, "Rain-drops." 3. Mr. W. B. Tripp, "Levels of the River Vaal at Kimberley, South Africa, with remarks on the Rainfall of the Watershed."

Microscopical, 20, Hanover-square, W., 8 p.m. 1. Mr. P. T. Lewis, "The Organs of Oviposition in certain Cattle Ticks." 2. Mr. E. M. Nelson, "The Penetrating Power of the Microscope" and "The Rings and Brushes of Crystals."

Pharmaceutical, 17, Bloomsbury-square, W.C., 11 a.m. Annual Meeting.

Archæological Association, 32, Sackville-street, W., 8 p.m.

Botanic, Inner Circle, Regent's-park, N.W., 2 p.m. Summer Exhibition.

United Service Institution, Whitehall-yard, S.W., 3 p.m. Discussion on the subject of the Naval Essays, "Maritime supremacy being essential for the general protection of the British Empire and its Commerce, to what extent, if any, should our Naval Force be supplemented by fixed defences at home and abroad, and to whom should they be confided?"

THURSDAY, MAY 19...SOCIETY OF ARTS, John-street, Adelphi, W.C., 4½ p.m. (Indian Section.) Mr. Jervoise Athelstane Baines, "The Administration of the Imperial Census of 1891 in India."

Royal, Burlington-house, W., 4½ p.m.

Antiquaries, Burlington-house, W., 8½ p.m.

Chemical, Burlington-house, W., 8 p.m. 1. Mr. W. H. Perkin, "Magnetic Rotation of some Acetyl Derivatives." 2. Mr. A. R. Ling, "Studies on Isomeric Changes; No. IV., Halogen Derivatives of Quinine (Part I.)." 3. Messrs. E. R. Moritz and T. A. Glendinning, "Note on Diastalic Action." 4. Dr. Kipping, "Formation of the Hydro-Carbon $C_{18}H_{12}$ from Phenylpropionic Acid."

Encouragement of Fine Arts, 9, Conduit street, W., 8 p.m. Mr. Philip H. Newman, "The Chronology of Costume," Part II. (Mediæval and Modern Times).

Royal Institution, Albemarle-street, W., 3 p.m. Professor Dewar, "The Chemistry of Gases." (Lecture IV.)

Electrical Engineers, 25, Great George-street, S.W., 8 p.m.

Historical, 11, Chandos-street, W., 8½ p.m. Prof. Montagu Burrows, "Publication of the Gascon Rolls by the English and French Governments."

Camera Club, Charing-cross-road, W.C., 8 p.m. Mr. H. P. Robinson, "A Note on Feeding, and our Debt to Science."

Numismatic, 22, Albemarle-street, W., 7 p.m.

FRIDAY, MAY 20...United Service Club, Whitehall-yard, S.W., 5 p.m. Major E. Satterthwaite, "The late War Game in the Open."

Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting, 9 p.m. Mr. J. Wilson Swan, "Electro-Metallurgy."

Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.

Physical, Science Schools, South Kensington, S.W., 5 p.m. 1. Mr. R. Inwards, "An Instrument for drawing Parabolas." 2. Mr. F. H. Nalder, "Some Electrical Instruments." 3. Messrs. E. Edser and H. Stansfield, "An Instrumeut for measuring Magnetic Fields."

SATURDAY, MAY 21...Royal Institution, Albemarle-street, W., 3 p.m. Mr. E. Dannreuther, "J. S. Bach's Chamber Music" (Lecture IV.)

The Telegraphic Address of the Society of Arts, and of the Royal Commission for the Chicago Exhibition, is "Praxiteles, London."

Journal of the Society of Arts.

No. 2,061. Vol. XL.

FRIDAY, MAY 20, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

CONVERSAZIONE.

The Society's *conversazione* is fixed to take place at the South Kensington Museum (by permission of the Lords of the Committee of Council on Education) on Wednesday evening, June 29th.

Each member will receive a card for himself, which will not be transferable, and a card for a lady. No tickets will be sold.

Further particulars as to arrangements will be announced in future numbers of the *Journal.*

PRACTICAL EXAMINATION IN VOCAL AND INSTRUMENTAL MUSIC.

The next examinations will be held by Sir John Stainer, Mus.Doc., and W. G. McNaught, A.R.A.M., joint Examiners, at the House of the Society of Arts, and will commence on Thursday, 9th June. No names can be received after Monday, 23rd May.

Full particulars can be obtained on application to the Secretary.

CANTOR LECTURES.

On Monday evening, 16th inst., Professor Percy F. Frankland, Ph.D., F.R.S., delivered the third lecture of the course on "Recent Bacteriological and Chemical Research in connection with the Fermentation Industries,"

The lectures will be published in the *Journal* during the autumn recess.

FOTHERGILL PRIZE.

The following Report of the Committee on the award of the Fothergill Prize has been received and approved by the Council.

List of the Committee. — The Attorney-General M.P., Chairman of the Council, Sir Frederick Abel, K.C.B., D.C.L., F.R.S., Sir Frederick Bramwell, Bart., D.C.L., F.R.S., Thomas Edward Collcutt, F.R.I.B.A., Major-General J. F. D. Donnelly, C.B., Sir Douglas Galton, K.C.B., D.C.L., F.R.S., William Henry Preece, F.R.S., Edward Terry, Sir Henry Trueman Wood, Secretary.

In answer to the offer made under the terms of the Fothergill trust, of a Society of Arts Gold Medal or £20, for "the best Invention having for its object the Prevention or Extinction of Fires in Theatres or other places of amusement," eighteen competitors submitted designs, models, essays, samples, or suggestions. The Committee regret that, after a careful examination of the various proposals, they cannot find any one which they consider of sufficient merit, and coming sufficiently within the terms of the offer, to justify them in recommending it for the distinction of a Society of Arts Medal. They regret this the more because, on the last occasion when the medal was offered, in 1884, for a similar object, the resulting competition was equally unsuccessful.

On that occasion, Mr. E. A. Woodrow submitted an essay on the subject, which was published in the *Journal of the Society of Arts* for April 18, 1884. The same gentleman has adopted a similar course on the present occasion, and has sent in an essay, which the Committee consider possesses considerable merit as a *resumé* of the points to which experience has shown that attention should principally be directed in theatre construction, so far as regards the safety of the audience. They do not feel that they are empowered to make any award for an essay, but they recommend that Mr. Woodrow's contribution should be published in the Society's *Journal,* as they believe that it contains information of public value.

Mr. S. B. Wilkins, Fire-Master of Edinburgh, submitted a very elaborate model of a theatre, fitted up with appliances for preventing and extinguishing fire. Many of the appliances employed have been a considerable time in use; some even have, in the opinion of the Committee, been improved upon; but the proposed arrangements are very complete, and have evidently been most carefully thought out. A theatre, fitted up on the plan illustrated by Mr. Wilkins's model,

would be in advance of any but those of the most recent and advanced construction.

Mr. Shean submitted an ingenious combination of a ladder with fire-hose and jet, and fitted with a specially shaped axe for cutting away burning scenery. The Committee hesitate to express any opinion on this device, and they were not informed as to its having been practically tested. It is at least an open question, with regard to the value of the axe, whether it is often advisable to cut down the burning material, and whether, when this has to be done, the work cannot better be carried out from the flies.

Messrs. Messer and Thorpe submitted a very handy and simple method of fitting buckets, one within the other, inside a reservoir or cistern. As the first bucket is lifted out, full of water, the second, within which the first was fitted, instantly fills and can be lifted out, and so on throughout the series. A large number of buckets can thus be stored with great economy of space. The cistern may merely contain sufficient water to fill all the buckets, or may be supplied by a ball-tap.

Messrs. Blanchard, and Messrs. Mark Fawcett and Co., showed samples of their methods of fire-proof construction. The Committee have no hesitation in commending both, but they do not consider that generally applicable methods of construction, not specially intended for theatres, come within the terms of the offer.

Messrs. Davis and the Cyanite Company submitted samples of fireproofing solutions and paints. The value of such materials, and the limits within which they are applicable, are now well known. It is to be desired that they were more extensively used than they probably are. The Committee cannot see that those submitted present sufficient novelty to justify them in recommending an award to it. The Committee may refer to the account of these materials contained in the *Journal* of May 25, 1883, as an appendix to the Report of the Committee on Prevention of Fires in Theatres.

Messrs. Warbey sent some "sprinklers;" and some other examples were also submitted of this now well-known class of appliance by Mr. S. B. Wilkins.

The other proposals submitted to the Committee do not, in their opinion, call for any remark.

The Committee, in deciding that they could not recommend any award of the Society's medal, considered that no good purpose would be served by making an award to any invention which was not of decided novelty, importance, and value. The competition was not successful in bringing out any such invention, and, in reporting this to the Council, the Committee recommend them to consider whether some course other than the offer of a prize medal might be adopted, whereby the excellent intentions of the founder of the fund might be likely to be more usefully carried out.

Chicago Exhibition, 1893.

MEETING OF THE ROYAL COMMISSION.

A meeting of the Royal Commission was held on Wednesday, 18th inst. Present: The Attorney-General, M.P., Q.C., in the chair; Sir Frederick Abel, K.C.B., D.C.L., F.R.S., Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., Sir Edward Birkbeck, Bart., M.P., Sir Frederick Bramwell, Bart., D.C.L., F.R.S., Sir Owen Tudor Burne, K.C.S.I., C.I.E., Michael Carteighe, Francis Cobb, General J. F. D. Donnelly, C.B., Sir Henry Doulton, Francis Elgar, LL.D., Sir Douglas Galton, K.C B., D.C.L., F.R.S., Thomas Hawksley, F.R.S., C. Malcolm Kennedy, C.B, G. Matthey, F.R.S., J. Fletcher Moulton, Q.C., F.R.S., Prof. W. C. Roberts-Austen, C.B., F.R.S., Sir Saul Samuel, K.C.M.G., C.B., with Sir Henry Trueman Wood, M.A., as Secretary.

PHOTOGRAPHIC COMMITTEE.

The first meeting of the Photographic Committee was held on Friday, 13th instant. Present: B. Francis Cobb (Chairman of the Committee), George Davison, Colonel Joseph Gale, H. P. Robinson, and Sir Henry Trueman Wood, Secretary of the Royal Commission.

APPLICATIONS FOR SPACE.

Intending exhibitors are reminded that applications can only be received up to Saturday, 21st May. Any applications received after that date will be filed, in case of any space becoming hereafter available, but will not be included in the allotment.

All applications must be made upon forms to be obtained from the Secretary of the Commission at their offices, Society of Arts, John-

street, Adelphi, London, W.C. They must be sent in, properly filled up, and addressed to the Secretary, as above.

Proceedings of the Society.

TEMPORARY ALTERATION OF BYE-LAWS.

In accordance with the notice duly given, a General Meeting of the members was held at the Society's House on Wednesday, 18th inst., the ATTORNEY-GENERAL, Q.C., M.P., in the chair.

The SECRETARY read the notice convening the meeting as follows :—

The Council hereby convene a General Meeting of the members to be held at the Society's House, in the Adelphi, on Wednesday, the 18th May, 1892, at 4 o'clock in the afternoon, for the purpose of considering, and if thought desirable of passing, the following resolutions :—

1. That in accordance with the proposal from the Council, the Bye-laws be altered and varied in such manner that the Council shall be empowered, during the years 1892 and 1893, to appoint not more than six members to be Vice-Presidents or other Members of the Council in addition to those appointed under Bye-laws 79 and 84, and that the Council be empowered to determine the period or respective periods that members so appointed shall continue in office, not being later than the end of the Session commencing 1893, and that all Bye-laws which are inconsistent with such appointment and determination be suspended or varied.
2. That Bye-laws 8, 9, and 10 be suspended during the Sessions 1892-3 and 1893-4.

Bye-Laws 8, 9, *and* 10.

8. The Chairman of the Council shall be chosen from those Members of the Council who are of one year's standing at least.

9. The Chairman of the Council, after two years' service, shall not be re-eligible to the office for at least one year.

10. The Chairman of the Council shall deliver an address to the Society at its Ordinary Meeting after his election.

The CHAIRMAN said—Gentlemen, I will just say a word or two in order to explain to the members present, who have not been in communication with the Council before, the object of the proposed alteration of Bye-laws. You are aware that the Society of Arts is governed by a charter, and by certain regulations under which the members of the Council must go out of office after a certain number of years' service, either as Members of Council or as Vice-Presidents. You are also aware that in the summer of last year Her Majesty was graciously pleased to appoint the Council of the Society of Arts the Commission for the Chicago Exhibition. Work of an important character has been thrown on the Council, and I think the members of the Society of Arts have approved the duties and conditions imposed on the Society by the gracious act of Her Majesty. Now, there are upon the Council at present some two or three gentlemen who have great experience in Exhibition matters, who would, by the ordinary rules of the Society, be unable to serve during the coming yea[illegible] and I am sure th[illegible]the members would regre[illegible]the loss of coun[illegible]rs so particularly qualified [illegible]o assist and guid[illegible] Council on these mat[illegible]s. Therefore, whi[illegible] should propose for elec[illegible]on, in the ordinary [illegible] gentlemen to fill the o[illegible]e of Vice-President[illegible]d Members of Council in accordance with the Bye-laws, it has seemed fit to the Council, after considering the matter in committee, to recommend that there s[illegible] be for two years this alte[illegible]on of the Bye-laws, [illegible] that six members of the Society should be appo[illegible] Vice-Presidents or Members of Council, in additi[illegible] those who would be appointed under the Bye-la[illegible] they stand. That would enable the Council to ap[illegible] any gentleman whom they consider specially qualified to assist the Council. The other Bye-laws are minor matters, dealing with the actual duties to be performed by those who have had to serve on the Council, and by the Chairman. They are not of much importance, and I do not apprehend that anyone will require further explanation as to them. I am sure the members will think the Council have been considering the interests of the Society in proposing these alterations; and, with these observations, I beg to move the alteration of the Bye-laws. If any gentleman has any question to ask, I shall be happy to answer him.

Sir FREDERICK BRAMWELL—As this is a proposition emanating from the Council, I think, as Vice-Chairman, I should second it. I will not take up your time by adding any observations to those made by Sir Richard Webster, as I am sure he has fully explained the intention and object of the proposed alteration.

The resolution was put and carried unanimously. The meeting was then closed.

APPLIED ART SECTION.

Tuesday, May 17, 1892; General ROBERT MACLAGAN in the chair. The paper read was, "Mud, a Material for Architecture in Persia and the East," by WILLIAM SIMPSON, R.I.

The paper and report of the discussion will be printed in an early number of the *Journal*.

TWENTY-FIRST ORDINARY MEETING.

Wednesday, May 18, 1892; R. BRUDENELL CARTER, F.R.C.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as members of the Society:—

Cassavetti, John, The Cedars, Torquay, and Exeter College, Oxford.
Corsan, John Richard, 5[illegible], Gray's-inn-road, W.C.
Elli[illegible], John, Derwent-h[illegible]e, Upper Villiers-street, [illegible]olverhampton.
Ellwood, Thomas Ashcroft, 13, Cavendish-road, Harringay, N.
Little, Thomas David, Public Works Department, Bombay, India.
[illegible], William Graham, [illegible], Cannon-street, E.C.
[illegible]hall, William Bayley, Richmond-hill, Birming[illegible]m.
[illegible]te, Henry, 80, London-road, Carlisle.
[illegible]rtzburg, John Henry, care of Messrs. Greenwood and Batley, Albion Works, Leeds, and 2, De Grey-road, Leeds.

The following candidates were balloted for and duly elected members of the Society:—

Bamber, M. Kelway, Seleng, Jorehat, Upper Assam, India.
Griffith, Frank, Prujean-square, Old Bailey, E.C.
Grimes, Arthur John Luna, Telegraph Department, Bombay, India.
O'Connor, John, M.P., House of Commons, S.W.
Townend, James Hamilton, Haberdashers'-hall, Gresham-street, E.C.

The CHAIRMAN announced, with much regret, that the death of Capt. Abney's father had compelled him to be absent, but they were greatly indebted to Capt. Abney's colleague at South Kensington, General Festing, for coming forward, not only to read the paper, but also to supervise the conduct of the very beautiful experiments by which the paper would be illustrated; these were the result of Captain Abney's recent work, with which General Festing had been intimately associated.

The paper read was—

COLOUR BLINDNESS.

BY CAPTAIN W. DE W. ABNEY, C.B., F.R.S.

I do not wish to-night to bring forward any debateable points on the subject of the theory of vision. What I want to do is to deal with facts, and facts alone; at the same time illustrating some of these facts experimentally by the methods which General Festing and myself have initiated and used in the investigations which we have described in papers to the Royal Society from time to time. A committee appointed by the Council of the Royal Society has been investigating the subject of the best tests to employ for detecting colour blindness, and in the capacity of secretary to that committee I have had unusual opportunities of examining cases by spectral methods, and have found that the interest in colour vision increases the more it is investigated in a scientific spirit.

The early history of the discovery of the existence of colour blindness I need not enter into. History has a charm for many, but I confess that ancient history, *quâ* history alone, has very little charm for me, and I prefer to deal with the present rather than with the past. I shall, therefore, leave to the lover of history a page which he can fill up for himself in this paper, merely mentioning the fact that Daltonism was a name given to colour blindness from Dalton, the chemist, and that in France, even to the present time, this kind of abnormal vision is still characterised by this word.

Colour blindness we may divide into two classes—1st, congenital, and 2nd, that induced by disease; and we shall see that these differ very widely in character, the latter, indeed, being in some respects a greater defect than the former.

Congenital colour blindness is very varied in its phases, and I propose to describe these by referring to the spectrum. When a person possessing normal vision looks at the spectrum, he will tell you that he sees six or seven colours —red, orange, yellow, green, green-blue, blue, and violet; and these all appear to occupy well defined spaces in the spectrum. Now, about 96 per cent. of males see these colours in the same relative positions, and in the same fairly defined limits. But, if we take the remaining 4 per cent. of males, or perhaps a rather greater percentage, we shall find that they describe the spectrum in a totally different manner. If by some means we are able to show any part of the

spectrum alone, they will describe the colours very differently to that in which they would be described by those whose perception of colour is normal. Some will see no colour and no light in the part of the spectrum which lies near the limit of the red. They will call a bright red green, or yellow, or sometimes red, and they will also be liable to call a green the same, but what their sensation is can be readily judged by a little artifice. Before describing this artifice, I will show you a diagram of the Young-Helmholtz theory of colour vision, which I shall use, not as accepting it in its entirety, but as explanatory of a good deal. It will be seen, on reference to the diagram, that there are supposed to be only three sensations of colour, one which gives the impression of violet, another of green, and another of red. The stimulation of each of these colour sensations is effected by rays occupying a long range of the spectrum; but at the extreme ends of the spectrum only one sensation is at all excited. For a sensation of the intermediate colours, two, or all three, of the sensations have to be stimulated. Thus in the green, the red and the violet and green sensations are excited, but the green more than the other two, and, as in the diagram, an equal stimulation of all three sensations means the perception of white light, we have where the red and violet perception curves cut one another more than sufficient green sensation excited to produce white alone. We have, therefore, a surplus of green sensation excited over and above that necessary for the production of white. The green of the spectrum is, therefore, to the normal eye, the pure green produced by the green sensation diluted with white light. In the same way we might deduce the sensations produced by other colours; thus orange is a slight stimulation of the green sensation with more of the red sensation, but, as before said, at only the extreme limits of the spectrum is one sensation excited. In fact, it may be said that no normal-eyed person has ever felt a pure green sensation, though he has felt a pure red and a pure violet sensation. Setting this aside for the moment, we may prognosticate what would happen (supposing of course the Young-Helmholtz theory were true) if any one or two of the three sensations were absent. Evidently if the red sensation were absent, the eye would see a pure green sensation at one end of the spectrum and a pure violet at the other, but intermediately they would see mixtures of green and violet. Where the curves of these two remaining sensations cut one another, the colour then would be of the same hue as the colour of white light; for it must be remembered that each of the curves in the diagram is supposed to have equal areas. This being so, it is evident that, as the curves are of equal height, were they cut, the colour at the point of the spectrum is the same to them as white. Further, it will be seen that this white or neutral colour is mixed up with both the green and violet sensations more or less, except at the extreme ends of the spectrum; and that where the extreme red is, no light should be perceived; but in the orange and scarlet the sensation will be nearly pure green. This then is a type of red blindness. Now, having taken this view of the matter, we may anticipaté that the colour-blind man, who answers to this description, can readily be deceived as to what is the true colour by an artifice. As a rule, the colour-blind are very acute in the perception of differences of dilution of colour with their neutral colour, and of the brightness of the colour itself. If, then, we have a means of mixing with, what to the normal eye is (say) orange, a variable proportion of white, which, remember, is also to him his neutral colour, he will be unable to distinguish it from a green. To effect this, we can use the apparatus I have described before in these rooms, superposing a white patch of light over a patch of any spectrum colour I may wish to use. If, therefore, we in practice dilute an orange patch of light with white, there will be no difference in hue with some green, and although the colour-blind may have been educated to call the spectrum colours by their right name under ordinary conditions, yet through the more or less dilution with neutral colour—*i.e.*, this mixture of white light with it—will at once destroy what may be termed the landmarks he has set up in his mind, and he will confound them with others. From the diagram it will be evident that, if the patch were orange, it will, when diluted with white light, be to him the same as the yellowish-green of the spectrum. As before indicated, he will see a neutral coloured space in the spectrum, and, on one side of this neutral colour, blue, and on the other what the normal-eyed call green, both mixed more or less with this neutral colour as the neutral point is approached.

If the green sensation be absent from an eye, according to this provisionally accepted theory, then there would still be a neutral point

in the spectrum which, for the same reasons as those given before, the colour-blind of this type would mistake for what to him is white; but the spectrum would remain of the same length as it is to the normal eye. This is a case of green colour-blindness. By mixing a red with white, the colour-blind would be totally unable to distinguish between red and green, as in the other case. Both cases are not uncommon, and it has been remarked that these last often call the colours they see on one side of the neutral point in the spectrum "yellow," whilst on the other they correctly call it blue. The reason of their colour nomenclature is not far to seek. They get their ideas of colour from normal-eyed persons, and fix upon the brightest objects as their standard, and these are yellows. A look at the diagram shows that to them the yellow is a bright and almost pure sensation, though it is probably red.

Another case of colour-blindness is when the violet sensation of this theory is absent, and I have only met with one example of it at all. The spectrum appeared to end about G, but by subsequent examination he was able to trace it as having a very feeble existence for some distance beyond. This colour-blind person also had a point in the spectrum which he mistook for white. This was in the yellow, a point where, according to the theory, it ought to exist.

Two other cases, which are of special interest, have now to be described. They are cases where one sensation alone was present; every colour was the same to them as white: blue, yellow, red, green, were all grey—that is, degraded white—and it was immaterial to them what colour they were asked to match; by sufficiently reducing the intensity of those which to them were the brightest, they were able to describe them as exact matches with the feebler colours. Thus a blue and a red would be made to match exactly in intensity and, of course, in colour. By matching the various points of the spectrum with different shades of grey, by the method which I have twice described in this room, the relative brightness of the different colours of the spectrum as felt by them was readily measured, and is that shown in the diagram, with a maximum at E in the green.

Now all light, if made feeble enough, can be extinguished to the eye, although it is really present; and measures have been made of the extinction of every colour of the spectrum. It was found that when the D (sodium) light of the spectrum had the same illuminating value as an amyl lamp (AL), a screen placed one foot off the source of illumination was just not seen when it was reduced to 350-10,000,000th of an AL, whereas the E light of the unaltered spectrum had to be reduced to 65-10,000,000th. The F light had to be reduced to 150-10,000,000th, and the C light to 11,000-10,000,000th, as will be seen by the following Table. If we make the light of the

	Extinction of light in 10 Millionths.
B	50,000
C	11,000
D	350
E	65
F	150
G	3,000

different parts of the spectrum each equal to one AL, it will be found that the extinctions at the violet end and at the extreme red are uniform, the violet end requiring the reduction 150-100,000,000th AL to render the screen invisible. This indicates that only one sensation is extinguished at the violet end and one at the red end — (this agrees with the Young-Helmholtz theory, it will be remembered) — but that the red sensation is 125 times more easy to extinguish than the violet sensation. If then we take the reciprocal of the extinctions of the spectrum, we shall get a curve which gives the last sensation which is extinguished, and making the maximum empirically 100, we find that it is really exactly the same sensation as the two cases of mono-chromatic vision, and corresponds to the violet sensation of the normal vision of the theory. By measuring the extinctions of the red and green-blind, we get almost identical results with those of the normal eye. Further, if the spectrum be reduced in intensity, so that the measured luminosity of the white light which forms the spectrum is 1-150th of that of an AL, 1 foot from a white screen, and measure its luminosity, we find that the same curve results. We are therefore led to the conclusion that the primitive sensation of light is the violet sensation, and that the others are "under-tones" of this one sensation. It is not therefore surprising if an "under-tone" is either totally missing or reduced in intensity, and this would correspond to complete and incomplete blindness to one colour sensation. There is a remark-

able confirmation of this in another way, viz., that those who are colour-blind from disease invariably, as far as I know, see blue at the blue end of the spectrum, the remaining part being generally described as grey, and sometimes yellowish. An examination of the various types of colour blindness with the spectrum, and with colour discs, shows that the whites which they see are, to the normal eye in the case of the red-blind, a sea-green colour, of the green-blind a red-purple, and of the violet-blind a yellow. These can well be shown by colour discs as well as by the spectrum.

From what has been said, it will be apparent that, by the spectrum, colour blindness of any type can be detected simply by diluting the different colours. Thus, a first test to be made would be to take a green of the spectrum, and dilute it with white light. Even to the normal eye, the green can be made to lose itself in the white; much more easily can it lose itself to the colour-blind, since it is to them nearly white already. An experiment will show this. Other tests of diluting red and yellow can also be made, and a good estimate made without quantitative measurement of the amount of colour deficiency present; for, it must be remembered, that it often happens that complete blindness to one sensation does not arise. The spectrum method is often impracticable and expensive, and therefore other methods to attain the same end have to be sought for.

The question of such tests for colour blindness has been carefully considered by the Committee of the Royal Society, and from all the experiments made, and from careful consideration of all cases which have come before them, they have reported that Holmgren's wool test, as originally brought out by that distinguished *savant*, is the most practicable and practical test which can be employed. This test really consists in making a person illustrate his deficiencies by the mistakes he makes in matching different colours, and answers to the spectrum test described.

The tests are wools, which I show here to-night. It will be seen that they are of almost every variety, but amongst them are shades of greys, drabs, and browns. The skeins which have to be matched are pale green of a slightly yellowish tint, a pale pink, and a bright red. The first test is to ask a candidate to pick out from a heap of wools skeins which appear to match in colour generally the green skein. Now this green skein has a hue which lies on the red side in the spectrum of the neutral points of both the red and the green-blind; and as it is very largely diluted with white, it will be seen, from what has been said before, that it may be matched with a grey, or a drab, or a yellow, or a light red, but not with any skein of wool which has a blue tint. If these colours are absolutely selected, then the examinee is colour-blind; but if he only evinces a desire to do so, he is only incompletely colour defective. This fact can be proved by testing the person by the spectrum method in the manner already indicated.

The next test is with the pink skein, as it is with this that the kind of colour defects on the Young-Helmholtz theory can be ascertained. If the candidate matches blue, green, and grey, or one of them with the pink, he is completely green-blind, but if he selects blues and violets he is completely red-blind. If he matches with the pink skein only pink he is incompletely colour-blind. The last test with the red skein is almost superfluous, but with this bright red skein a red-blind person will make a selection of dark green and brown, whilst if he be green-blind he will select a bright green and a light brown. All these tests can be proved to be correct by the spectrum method, and they, therefore, leave but little to be desired. As before said, it is these tests that the committee have recommended for adoption, and they are simple and cheap, but the whole efficiency of them lies in the selection of the colours to be matched. If the first test were a blue green or a bright green, it would be useless, as the matches made would mean very little, and the same applies to the pink skein. It is for this reason that the committee have recommended that there should be standard test skeins and no others. It has come to our knowledge that some railway companies have imagined they were using Holmgren's test, when they were doing nothing of the kind, and this simply because the test and skeins offered to the candidate to match were of the wrong hue and dilution.

The recommendations of the committee of the Royal Society are as follows:—

1. That the Board of Trade, or some other central authority, should schedule certain employments in the mercantile marine and on railways, the filling of which by persons whose vision is defective either for colour or form, or who are ignorant of the names of colours, would involve danger to life and property.

2. That the proper testing, both for colour and

form, of all candidates for such employments should be compulsory.

3. That the testing should be entrusted to examiners certificated by the central authority.

4. That the test for colour-vision should be that of Holmgren, the sets of wools being approved by the central authority before use, especially as to the correctness of the three test colours, and also of the confusion colours. If the test be satisfactorily passed, it should be followed by the candidate being required to name without hesitation the colours which are employed as signals or lights, and also white light.

5. That the tests for form should be those of Snellen, and that they should be carried out as laid down in Appendix VI. [Form test]. It would probably in most cases, suffice if half normal vision in each eye were required.

6. That a candidate rejected for any of the specified employments should have a right of appeal to an expert approved by the central authority, whose decision should be final.

7. That a candidate who is rejected for naming colours wrongly, but who has been proved to possess normal colour-vision, should be allowed to be re examined after a proper interval of time.

8. That a certificate of the candidate's colour-vision and form-vision according to the appointed tests, and his capacity for naming the signal-colours, should be given by the examiner; and that a schedule of persons examined, showing the results, together with nature of the employments for which examinations were held, should be sent annually to the central authority.

9. That every third year, or oftener, persons filling the scheduled employments should be examined for form-vision.

10. That the test in use, and the mode of conducting examinations at the different testing stations, should be inspected periodically by a scientific expert, appointed for that purpose by the central authority.

11. That the colours used for lights on board ship, and for lamp signals on railways, should, so far as possible, be uniform, and that glasses of the same colour as the green and red sealed pattern glasses of the Royal Navy, should be generally adopted.

12. That in case of judicial inquiries as to collisions or accidents, witnesses giving evidence as to the nature or position of coloured signals or lights should be themselves tested for colour- and form-vision.

It will be seen that these recommendations are very comprehensive, and I am sure have only been recommended after careful deliberation on the subject. It remains for the Board of Trade to see them carried out intheir entirety, and if legislation be required, then there should be legislation.

DISCUSSION.

The CHAIRMAN said the report of the Royal Society's Committee was not yet published, though some stray copies had got about, and had been commented upon in certain journals, but the Council of the Royal Society at their next meeting would determine what should be done with it. It would, he believed, be presented to the Board of Trade, and by it to Parliament, and would then be accessible to the public in the ordinary way. There was a special fitness in the conclusions of the Committee being first made public in that room, because the subject of colour blindness was one of many in which the Society had taken the initiative. Eleven years ago on Monday, he delivered the first of a series of Cantor lectures on "Colour Blindness," and then endeavoured to point out that, in consequence of the complication of railway work and the crowd of vessels in many parts of the sea the question of colour-blindness had become one of grave practical importance. Although certain railways were then beginning to test their officials, and though the Board of Trade was testing candidates for the mercantile marine, neither the railways nor the Board were pursuing methods of investigation which could be relied upon, and both were rejecting candidates who ought not to be rejected, and passing those who were unfit for responsible positions in which a sense of colour was required. Some improvement took place, but not very much, and, two or three years ago, a good deal of dissatisfaction was excited amongst railway men by the methods of examination pursued by certain companies professing to use Holmgren's test; although the only point of resemblance to it was that coloured wools were used. The colours were improperly selected, and the test was practically worthless. In consequence, he was asked by the Council to read a paper on the subject, and on that occasion Dr. Edridge Green questioned some of the conclusions at which Young and Helmholtz had arrived, and subsequently, on his suggestion, communicated a paper to the Royal Society, endeavouring to substantiate the views he entertained, and to show in what respect those of Young and Helmholtz were erroneous. In consequence of the debate which ensued, the Royal Society, after communicating with the Board of Trade, appointed the committee, which had been at work for something like two years, of which Captain Abney was the Secretary, and some of its recommendations had just been read. He was pleased to find that these recommendations confirmed in every particular the suggestions made in his Cantor lectures of eleven years ago. The Committee of the Royal Society contained some of the most distinguished scientific men in England, including Sir George Stokes, and was presided over by Lord Rayleigh, those two gentlemen being the leading optical philosophers of this or any other country. It also included Captain Abney, who made a large number of most careful experiments,

and Professor Church, Professor of Chemistry to the Royal Academy, who was necessarily conversant with colour in every variety. The results of Captain Abney's work had made clear certain points which had previously been obscure, but still left the doctrines of Young and Helmholtz in possession of the field. He did not claim that they supplied a full explanation of the phenomena, but that they explained more than any other hypothesis, and he had no doubt Captain Abney would continue his researches until the deficiences were supplied. He hoped when the report came before Parliament that it would be followed by legislative action. It might seem a hardship for certain men to be excluded from following certain occupations, but it was a far greater hardship that passengers in ocean steamers should be exposed to peril by the look-out man not being able to say whether the port or the starboard side of a vessel was approaching. Moreover, if it were known that these tests would be imposed, such examinations would be made in the case of children at school, and parents would learn, at an early period, that their children could not look forward to success in certain occupations, but must betake themselves to others. The colour-blind males in this country were about 4 per cent. of the population, but the Committee, who went down to Swindon, and were allowed to test a number of the men employed there by the Great Western Railway Company, were surprised to find a much larger proportion. They did not test the signalmen or drivers, but smiths, fitters, and other men employed in the shops, and it was found afterwards that the managers had considerable doubts about the efficiency of the methods pursued by the committee, and had included as many colour-blind as possible for the purpose of being tested. They found them all out, however, and, by means of actual signals, were able to demonstrate the absolute incapacity of the men who had been discovered to be red, blue, or green colour-blind by the Holmgren test, properly applied, to distinguish with certainty the different lights under all degrees of illumination. There was still, however, another difficulty to contend with. There were many cases of incomplete red or green colour blindness, men whose vision was defective in these respects; and a question might arise whether it was sufficiently defective to require their rejection. During his work on the committee he had contrived the instrument now exhibited, in order to test these cases of defective colour sense quantitatively. It consisted of a lamp, which, for minute tests, would probably be one of Mr. Vernon Harcourt's pentane standard lamps, which cast its light into the interior of a box through an opening, which could be increased in size, by turning a screw, from 1 to 1,500 square millimetres. You could thus light up an object in the interior to any extent, and measure the amount of illumination, and express it in terms of the size of the aperture. Then, as test objects, placed where the whole light admitted, large or small, would fall upon them, be placed little discs containing dots of various colours, varying also in number and in arrangement. A person with ordinary vision could not distinguish red by a bad light, and a person with incomplete colour sense would require more light still to distinguish it from green or black; so that, with this apparatus, he could arrive at a fair expression of the degree of acuteness or defect in any particular case. Some of the discs were opaque, and some translucent; and they would be viewed accordingly. In this way, he believed, very trustworthy results would be arrived at.

Mr. J. SPILLER said he had given a great deal of time and attention to this subject, and while he had come to the conclusion, on comparing notes with others who had been professionally engaged in the same direction, that the proportion of colour-blind males was about 4 per cent., he had hitherto failed to discover a woman with this defect, although he had been assisted in his search by ladies. Of course there were cases, and it was reported that they occurred particularly amongst Quakeresses, but hitherto he had not been able to find one. The ratio was said to be one colour-blind woman to every twenty colour-blind men, but he did not know whether this statement was founded on any actual statistics.

Dr. EDRIDGE-GREEN said he had listened with great interest to the paper, and also to the Chairman's description of his apparatus for the quantitative estimation of colour blindness. When at the Chairman's suggestion he read a paper before the Royal Society, he raised objections to the Young-Helmholtz theory of colour perception. No one had as yet answered them, and they had been admitted by a large number of scientific men. Undoubtedly, normal colour vision was trichromic, but whether that trichromatism was due to three points of difference, or to three definite colour sensations remained to be proved. Everyone must acknowledge the importance of the facts Captain Abney had brought forward, but they were all perfectly consistent with the theory of three primary points of difference. It would be seen from the diagram that the chief difference between a red blind and a green blind, consisted in the neutral point of the red blind being situated more towards the violet than the neutral point of the green blind. It would also be seen that the red end of the spectrum was shortened. He held that this moving of the neutral point in the red blind was due to the shortening of the spectrum. This neutral point varied very considerably. You might find the red end shortened very little; or, in some cases it was shortened to the orange; and then the neutral point was shifted in a corresponding degree towards the violet, which would not be the case if there were certain fixed definite colour sensations. Again, if you took away one of these primary colour sensations, you would alter the

shade of the whole spectrum, and not simply cut off a certain portion at the red end; but he found that some people with a shortened red end (through a blue-green glass which cut off those rays) would make a match similar to that of the normal sighted, thus showing that it was the shortening of the spectrum which produced the defect in colour perception. He was of opinion that shortening of the spectrum and colour blindness due to psychophysical perception were two totally distinct defects. He had met with several cases in which a person saw six colours in the spectrum, and yet had a spectrum shortened either at the red or violet end. This was analogous to persons who could not perceive high notes or low notes, which was a well known phenomenon. With regard to the Holmgren test, he was sorry to differ from such an eminent committee as had given an opinion in favour of it; but he was going to bring some cases before Captain Abney, and he would probably let those interested in the matter know the result. Those who were interested in the subject would find these objections in detail in his book on "Colour Blindness," in the International Scientific Series.

Mr. LOVIBOND said he was happily not troubled with any theory. He had listened with a great deal of interest to the remarks made in reference to the lowest luminosity of white light which was perceptible by the eye; and the work he had done, although not on parallel lines with that of Captain Abney, fully bore out the great discrepancy between the visibility of different colours. He had been able to measure in units the visibility of the several rays of normal daylight, and had found that any measurement such as that given was only true for a given time, and for a given light. The power of perception of normal light increased by time—he was not prepared to say it increased regularly—and there was a difference of perception for the several colours of normal light. For instance, dealing with a half-inch area of normal daylight, one which contained six spectral colours in equal colour proportions, as tested by the spectroscope, he found that the red ray was more quickly evident on first vision, but decreased in its perceptiveness more rapidly than the violet end, or rather the violet end increased by time at a greater rate than the red. After seeing the instrument of Captain Abney's several times, and carefully reading a description of it, he fancied it was hardly as perfect as it was represented as a measure of colour, though, as a matcher of colours, it might be absolutely perfect. The incident light might be normal, but one portion of the beam was transmitted through a prism, and thrown on the screen, while the portion with which it was compared was that reflected from an angle of the same prism. His experience of prisms and lenses was not large, but he had found that beams of light got by such means were never of exactly the same composition; therefore, in comparing the colours of the two portions of the beam in this, you might have a perfect match and yet a different composition. It was difficult to arrive at a correct judgment on these lines, because the masking of a given colour by white light was an important phase of the question, and the power of masking was dependent on the quantity of white light. It was possible to get a match of different colours, provided there was but small difference in the illumination, as the masking of the one would bring it down to the level of the other. There were many other points he should like to speak to, bnt he was not prepared without further consideration.

Admiral Sir ERASMUS OMMANNEY, C.B., F.R.S., said it was very interesting to know that the lights at present used in the navy were those approved of by scientific investigators. He must confess that during thirty years' experience at sea he had never found any serious defect of vision, either in the men on the look-out, or in the officer of the watch. He had sometimes differed from them as to the exact colour of the light, but that he accounted for by the atmospheric effects at great distances. Some people did not know whether they had one eye or two, for he recently knew a case in which a young man, who had a nomination for a cadetship, only discovered on undergoing the medical examination that he had but one eye to see with.

Mr. OLIVER J. WILLIAMS suggested that, in the event of any legislation taking place, some provision ought to be made for ensuring the proper colour in the glasses used for lamps. Not unfrequently what ought to be a white light had a yellow or greenish shade, which made it very difficult to distinguish, and the copper of the lamp, to some extent, affected the colour.

The CHAIRMAN said provision was made in the report for ensuring uniformity in the coloured glasses, but the question of white glass had not come before the Committee.

General FESTING, in reply, said he did not feel disposed to argue the question of the Young-Helmholtz theory, as it would take far too long; but he simply used it as a working hypothesis, because it seemed to him that it accounted for more than any other theory did. He understood Mr. Lovibond to say that the standard comparison beam would have a different composition of light to that which went through the prism, but he did not think that could be so. The difference between them was simply that the standard comparison beam had been reflected from the surface of the prism; and he was not aware that light suffered any alteration, except polarisation, by being reflected from the surface of white glass. The only way to test that would be by analysing the light by means of a prism or diffraction grating; and if any one tried that, he thought they would find the light reflected from the surface, when split up by another prism, would give the same

result as the rest of the beam which went through the first prism.

The CHAIRMAN, in proposing a vote of thanks to Captain Abney and General Festing, said that Mr. Spiller's observations about the ladies reminded him of what was said by a friend of his, who had had great experience in colour testing, to the effect that he generally found the first impulse of a woman, when she found her son to be colour-blind, was to box his ears. The researches in girls' schools, according to American statistics, had shown that there was about the same proportion of colour-blind in a thousand women as in a hundred men.

The vote of thanks was carried unanimously, and the meeting adjourned.

Miscellaneous.

PLATE-GLASS MANUFACTURE IN GERMANY.

The United States Consul-General at Frankfort, in his last report, says, in reply to instructions received from his Government to supply certain information concerning the grinding and polishing of plate-glass for mirrors as practised in Germany, that there is no manufacture or export of plate-glass in southern or western Germany, except in the consular districts of Aix-la-Chapelle and Fürth. At the latter place the United States Commercial Agent succeeded, in the face of many obstacles, in obtaining information upon the subject, the substance of which is given below. Consul Mason remarks that information upon the subject of plate-glass manufacture is all but impossible to obtain in Germany. The whole plate-glass manufacture in the Frankfort division is concentrated at the two places above-mentioned, and all the manufacturers are leagued in a syndicate or pool, and access to their works is rigidly denied to everyone, especially to Americans. The reason of this is, according to Consul Mason, that most of the German manufacturers live in fear that in some way Americans will discover the secrets of their trade and transfer their industries to the United States, with the result of ultimately destroying their best foreign market. The works, where nearly all the white German looking-glass used in the United States is blown, are situated near the borders of Bavaria and Bohemia, near the city of Egar in Bohemia. There are nnmerous large and extensive works besides innumerable smaller ones, the greater number of which belong to a pool, which regulates production, prices, &c. The greater part of the glass, when blown, ultimately finds its way to the city of Fürth, in Bavaria, where it is stored in a pool warehouse, whence it is delivered to members of the pool, no one outside that organisation being able to purchase a single square foot, the capacity of each manufacturer being well known, and no increase of manufacture above a certain per-centage being permitted. After leaving the glass-blower's hands the plates are quite rough, and it becomes necessary to grind them. There does not appear for some time to have been any material improvement in the method of grinding, though perhaps there has been in the machinery. The glass is fastened to a marble or cast bed of sufficient dimensions to receive the largest plates. If necessary, smaller plates are used to fill the table. The plates are held in place by a thin bed of plaster of Paris, the moisture of which holds them securely. The upper plate is turned upside down while the glass is being placed in position, and, when ready, is turned over carefully. Both the upper and lower beds revolve in different directions. The grinding material is coarse sand at first, a finer quality being used consecutively until the plate is finished. The time required varies, from sixteen to twenty-four hours being generally necessary for this process. The next process is that of polishing the plate, to make it transparent, preparatory to the silvering. The same kinds of beds are used as in grinding, with this difference, that they are stationary; and the plates are held in position in the same manner. The polishing is done by running square discs, covered with felt, backwards and forwards across the surface. The tables usually stand in dozens, six on each side, so that, as the the rubbers move backwards and forwards, no motion or power is lost. In most of the works, the disc revolves by the motion of sliding across the surface, but in one important factory a new polisher is in use, to which a rotary motion is given by chain gearing, which performs the work in about half the usual time—fifteen minutes instead of thirty. The polish used is a native Bavarian product, and is called *potte* or *bolus*, it being an earth strongly impregnated with iron, and is kept moistened during the process, one man being required to attend six machines. As many pieces of glass may be laid upon the polishing table as it has capacity for, it being generally thirty inches by ninety. If bevelling is required—and the greater number seem by the demand to require bevelling—the plates are removed to an iron or stone cylinder twelve to fifteen inches in diameter, revolving slowly, where the edge to be bevelled is held by the operator on the face of the grinder, moistened sand being applied at the same time to the stone. A frame at the end serves to hold the glass from slipping, and steps upon this, regulate the angle of the bevel. Expertness on the part of the workman is essential in this operation. From the grinding of the bevel, the glass is taken to a round polisher, where the bevelled surface is held upon a felt cylinder supplied with *potte* until it is polished. About fifteen minutes are required for this process.

Obituary.

Dr. A. W. HOFMANN, F.R.S.—August Wilhelm Hofmann, professor of chemistry in the University of Berlin, died suddenly on Thursday, 5th inst. Hofmann was born at Giessen, April 8, 1818, and, while still a young man, devoted himself, under the direction of Liebig, at the University of his native town, to the study of the bases of coal tar and metamorphoses of indigo, but it was not until several years later that his important discovery was made regarding the composition and chemical character of aniline red. After spending three years at Bonn, Professor Hofmann, in 1848, was, on Liebig's recommendation, appointed superintendent at the Royal College of Chemistry in London. This institution, in 1853, was merged in the Royal School of Mines. In 1864 Hofmann was appointed to the Chair of Chemistry at Bonn, whence he was summoned to Berlin in the following year. He was a voluminous contributor to scientific literature, and the "Royal Society Catalogue of Scientific Papers" contains a list of 240 papers, written between 1843 and 1874 by himself alone, and 21 papers written in conjunction with others. He was elected a Fellow of the Royal Society in 1851, in 1854 he obtained a Royal medal for his "Memoirs on the Molecular Constitution of the Organic Bases," and in 1875 the still further honour of the Copley Medal. In the latter year, he received the Faraday Medal from the Chemical Society. He was awarded the Albert Medal of the Society of Arts in 1881, "for eminent services rendered to the industrial arts by his investigations in organic chemistry, and for his successful labours in promoting chemical education and research in England."

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday evenings, at Eight o'clock:—

MAY 25.—F. E. IVES, "Researches in Photochromy."

FOREIGN AND COLONIAL SECTION.

Tuesday evenings, at Eight o'clock:—

MAY 24.—Colonel HOWARD VINCENT, C.B., M.P., "The Extension of Colonial Trade." The Hon. JAMES MUNRO, Agent-General for Victoria, will preside.

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock:—

MAY 31.—WILLIAM DE MORGAN, "Lustre Ware." Sir GEORGE BIRDWOOD, K.C.I.E., C.S.I., will preside.

CANTOR LECTURES.

Monday evenings, at Eight o'clock:—

Professor PERCY F. FRANKLAND, Ph.D., B.Sc., F.R.S., "Recent Bacteriological and Chemical Research in connection with the Fermentation Industries." Four Lectures.

LECTURE IV.—MAY 23.—Bacterial fermentations—New products resulting therefrom—Micro-organisms in their relation to agriculture—Nitrification—Fixation of atmospheric nitrogen by plants.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 23...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Cantor Lectures.) Dr. Percy F. Frankland, "Recent Bacteriological and Chemical Research in connection with the Fermentation Industries." (Lecture IV.)
Geographical, University of London, Burlington-gardens, W., 8½ p.m.

TUESDAY, MAY 24...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Foreign and Colonial Section.) Colonel Howard Vincent, "The Extension of Colonial Trade."
Royal Institution, Albemarle-street, W., 3 p.m. Prof. R. C. Jebb, "Some Aspects of Greek Poetry." (Lecture I.)
Medical and Chirurgical, 20, Hanover-sq., W., 8½ p.m.
Civil Engineers, 25, Great George street, S.W., 8 p.m. Professor W. C. Roberts-Austen, "The Measurement of High Temperatures."
Photographic, 5A, Pall-mall East, S.W., 8 p.m.

WEDNESDAY, MAY 25... SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. F. E. Ives, "Researches in Photochromy."
Geological, Burlington-house, W., 8 p.m.
Royal Society of Literature, 20, Hanover-square, W., 1 p.m.
Patent Agents, 55, Chancery-lane, W.C., 7½ p.m. 1. Discussion on Mr. J. Imray's paper. 2. Mr. Ernest de Pass, "Section 44 of the Patents Designs, and Trade Marks Act, 1883."

THURSDAY, MAY 26... Linnean, Burlington-house, W., 3 p.m. Anniversary Meeting.
Royal Institution, Albemarle-street, W., 3 p.m. Mr. R. G. Moulton, "Faust." (Lecture I.)
Electrical Engineers, 25, Great George-street, S.W., 8 p.m.
Camera Club, Charing-cross-road, W.C., 8 p.m., Mr. W. Willis, "The New Cold Development Platinotype Paper."

FRIDAY, MAY 27...United Service Club, Whitehall-yard, S.W., 3 p.m.
Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting, 9 p.m. Sir James Crichton-Browne, "Emotional Expression."
Clinical, 20, Hanover-square, W., 8½ p.m.

SATURDAY, MAY 21...Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.
Royal Institution, Albemarle-street, W., 3 p.m. Prof. H. Marshall Ward, "Some Modern Discoveries in Agricultural and Forest Botany." (Lecture I.)

The Telegraphic Address of the Society of Arts, and of the Royal Commission for the Chicago Exhibition, is "Praxiteles, London."

Journal of the Society of Arts.

No. 2,062. Vol. XL.

FRIDAY, MAY 27, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

EXAMINATIONS, 1892.

The results are now ready, and are in course of issue to the various centres of Examination, where all inquiries should be made.

CONVERSAZIONE.

The Society's *conversazione* is fixed to take place at the South Kensington Museum (by permission of the Lords of the Committee of Council on Education) on Wednesday evening, June 29th.

Each member will receive a card for himself, which will not be transferable, and a card for a lady. No tickets will be sold.

Further particulars as to arrangements will be announced in future numbers of the *Journal.*

CANTOR LECTURES.

Professor Percy F. Frankland, Ph.D., B.Sc., F.R.S., delivered the fourth and last lecture of the course on "Recent Bacteriological and Chemical Research in connection with the Fermentation Industries," on Monday evening, 23rd inst. On the motion of the Chairman a vote of thanks to the lecturer was passed unanimously.

The lectures will be published in the *Journal* during the autumn recess.

Chicago Exhibition, 1893.

FINE ARTS COMMITTEE.

A meeting of the Committee was held on Thursday, 19th inst. Present:—Sir Frederick Leighton, Bart., P.R.A., Chairman of the Committee; Wyke Bayliss, P.R.S. Brit. Artists, Philip H. Calderon, R.A., Alexander Henderson, F. Seymour Haden, P.R.S. Painter Etchers, Sir James D. Linton, P.R.I., Edward J. Poynter, R.A., Marcus Stone, R.A., W. Hamo Thornycroft, R.A., the Earl of Wharncliffe, Sir Henry Trueman Wood, M.A., Secretary of the Royal Commission, and J. W. Beck, Secretary to the Committee.

COLONIAL COMMISSIONER.

Mr. B. Howell Jones has been appointed Commissioner for British Guiana at the Chicago Exhibition, by Lord Viscount Gormanston, Governor of British Guiana.

HORTICULTURAL DEPARTMENT.

The following letter from Mr. Samuels, Chief of the Department of Horticulture, to Mr. McCormick, has been received for publication:—

World's Columbian Commission,
Office of the Director-General of the Exposition,
Chicago, Ill., U.S.A.,
14th April, 1892.

Hon. Robert S. McCormick, Official Representative, World's Columbian Exposition, London, England.

Dear Sir,—In reply to your request, made to the Chief of the Department of Foreign Affairs, for information concerning the growth and development of horticulture in the United States, I have the honour to make the following report:—

The census reports show that there were engaged in 1890, in the nursery business in the United States, 4,510 firms, with an invested capital of $52,425,669·51, and giving employment to 47,936 men and women; of this number only 42 were in existence prior to 1860; while even as late as 1870 only 436 firms were in business. In 1880, the number of nurseries had increased to 1,212, and thus the marvellous growth of the nursery interest can be illustrated in no better way than by stating that, in the space of one decade, the number of firms in the business has more than doubled, and the invested capital has been increased 75 per cent. $18,325,935·86 is shown to be invested in 596 seed farms, which, including the seed merchants, represents a small per cent. of the money invested in the seed trade.

Floriculture, as a commercial business, was almost unknown at the beginning of the present century. There was a total of 4,659 establishments in 1890; of these 2,795 have been started since 1870, and

1,797 since 1880. These establishments, including fixtures and heating apparatus, were valued at \$38,355,722·43, while the tools and implements used were valued at \$2,747,846·59; the wages paid in one year amounted to \$8,483,657. The sales for a single year in plants and cut flowers reach the grand total of \$26,211,805·77.

Even the great number of firms who have commenced business during the last decade have not been able to keep pace with the demand for horticultural products, and custom house receipts each year indicate larger orders from European firms. More than twenty houses in Great Britain have travelling agents who visit every State in our country, and sell annually 500,000 roses, 250,000 deciduous shrubs, 2,000,000 apple, pear, plum, and cherry seedlings, hundreds of thousands of gooseberries, currants, &c., 100,000 rhododendrons and azaleas, large quantities of palms and ferns, \$200,000 worth of orchids, and many tons of flower and vegetable seeds. It is safe to state that the United States is the best field, present and prospective, for Great Britain's horticultural productions.

The most enterprising firms of the United Kingdom appreciate the advantages to be derived from a creditable display at the Columbian Exposition, as they will there reach not only their patrons in this country, but from all parts of the world. Applications have been made for liberal amounts of space. Other firms, desiring to more widely cultivate a taste for horticulture, and let the world receive the benefit of their experiments in producing novel and choice varieties of trees and plants, have made large donations to the Exposition, and the department of horticulture is in almost daily receipt of fine collections.

There are some large and rare specimens of plants, which can only be procured at the world-famous Kew Gardens, and I am very anxious to secure the donation or loan of some of them. Any exhibits from Kew will be a great source of pride to Englishmen from all parts of the world. The following list of plants will be very desirable, and will attract universal attention:—*Aristolochia hians*, *A. longifolia*, *A. goldieana*, *A. ringens*; *Amorphophallus campanulatus*, *A. grandis*, *A. lacourii*, *A. nivesus*; *Dracontium albostipes*, *D. annulatum*, *D. aspersum*, *D. carderi*, *D. gigas*, *D. fecundum*; *Amorphophallus titanum*, *A. leopoldianus*, *A. teuszii*, *A. virosus*; *Dracontium polyphyllum*; *Pancratium guianense*.

There may be other curious specimens which could be supplied, and the Curator of the gardens will know the many unique and curious species and varieties that will be of interest to the millions of visitors.

The handling and care of exhibits will be under the control of the most skilled help obtainable, which fact will insure against loss; and, when desired, the safe return of all loans will be guaranteed.

Yours respectfully,

J. M. SAMUELS,
Chief, Department of Horticulture.

Proceedings of the Society.

TWENTY-SECOND ORDINARY MEETING.

Wednesday, May 25, 1892; J. W. SWAN, F.C.S., in the chair.

The following candidates were proposed for election as members of the Society:—

Benson, George Henry, Holly Lodge, St. Saviour's, Jersey.
Ketchley, Rev. H. E., B.A , Devon Lodge, Malvern.
Shaw, William Thomas, 110, Bunhill-row, E.C.
Skinner, Arthur B., B.A., 2, The Residences, South Kensington Museum, S.W.

The following candidates were balloted for and duly elected members of the Society:—

Castle, Sydney Charles Courtenay, 40, Chancery-lane, W.C.
Gubbins, John Harington, British Legation, Tokio, Japan, and Oriental Club, Hanover-square, W.
Smith, Sir Donald A., K.C.M.G., LL.D., Montreal, Canada.
Woolf, Mortimor, 16, Greville-place, N.W.
Wyatt-Davies, Ernest, B.A., Trinity College, Cambridge.
Young, Herbert Edward, White Hart-street, High Wycombe.

The CHAIRMAN, in introducing Mr Ives, said Mr. Ives needs no introduction to an English audience; his work in connection with the translation of the continuous gradation of an ordinary photograph into discontinuous gradation is known throughout the world. The excellent quality of the half-tone photographic engravings—so profusely employed in the illustrated literature of America—is largely due to Mr. Ives' initiative. But to-night we are to hear and see the results of his labours in a different direction, that of photography in natural colours, an object of desire that arose in the minds of almost the earliest workers in photography. No sooner had that miracle of science—the production of a photograph in light and shade—been wrought, than the insatiable striving after something higher and better — the best attribute of the human mind — asserted itself in the desire for colour in addition to light and shade; and very soon this desire received the stimulus of what appeared to be, if not a complete, at any rate, an approximate solution of this problem. In the Exhibition of 1851, I remember seeing a photograph on a Daguerreotype plate, which showed some quite vivid colours in the dress of a doll. It was a photograph by Becquerel, and it seemed as though very little more had to be done to realise a perfect result; but that seeming has proved to be illusive; the colours were, to a large extent, accidental, and they were not permanent, and as a matter of fact very little more has been accomplished since that time in that particular line of work-

ing. The colours were due, not to any selective action of the light corresponding to them, but to quantitive effect. The principle was false. The only substantial advance that has been made since that time has been made on the different principle of working, followed by Dr. Vogel and Mr. Ives; unless the recent announcement in connexion with the achievements of Mons. Lippmann should prove to be true. For 14 years past Mr. Ives has laboured to produce colour photographs by the composite method, believing that this was the only road by which success was to be reached.

The paper read was—

COMPOSITE HELIOCHROMY.

By F. E. Ives.

Most people look to original discovery for the solution of photographic problems, and most photographical problems are solved by original discovery. There have been a few important exceptions to the rule. The production of the so-called half-tone photographic block—the latest substitute for wood engraving—now grown to a very important industry, is one example. The first practical solution of this problem—a process which I patented in America, in 1881—was a purely mechanical invention, utilising photographic processes already known. The so-called Woodbury-type process is another purely mechanical invention, based upon well-known photographic processes. The method of colour photography, which I have named composite heliochromy, and which the French prefer to call photochromy or composite photochromy, is also an invention, utilising comparatively old and well-known photographic processes. It is not a simple invention, but comprises several inventions by different men. The original suggestion was made 27 years ago by her Majesty the Queen's painting master, Henry Collen.* Briefly stated, Collen's idea was to make three negatives of an object, one by red light, one by yellow, one by blue—the so-called primary colours of Brewster—to print from each pair of these negatives (superposed as one) a transparent positive having the colour (in the shadows) of the light that produced the third negative, and to superpose these coloured positives on a white surface. A Baron Ransonnet, of Austria, is credited with the same suggestion in the same year, but I have not the reference.

It was not possible to carry out Collen's suggestion at that time, because there was no known process by which photographic plates could be made sensitive to the separate single colours only; and no photographic plates were sensitive enough to red and yellow to admit of the production of such negatives by exposure through selective colour screens. Had it been possible to carry it out, the results must have been very imperfect, not only because the entire procedure is based upon a false and misleading theory of colour, but also because superposing two negatives to act as one, would double the intensity of such parts as represented white, grey, or pale coloured objects, with the result that if the colour prints were made to show all the details of the negatives, the finished heliochromes would show all bright colours as if mixed with equal parts of black pigment.

On November 23, 1868, Ducos Duhauron, of Paris, applied for a patent* for a process which differed from Collen's only in the manner of carrying out the same idea. Like Collen, he assumed that the spectrum is made up of three primary colour rays and mixtures thereof. He said, "My procedure rests on the principle that the simple colours are limited to three—the red, the yellow, and the blue—the combination of which, in divers proportions, produces the infinite variety of shades in nature." Like Collen, he expected to solve the problem by superposing red, yellow, and blue prints from negatives made by yellow and blue, red and blue, and yellow and red light. But instead of using plates sensitive to simple colours only, he proposed to use plates sensitive to all colours, and to prevent the action of colour rays not wanted by filtering them out with coloured glasses placed in front of the sensitive plates; and, instead of superposing two negatives to act as one to make a colour print from, he proposed to make two colours (that is, two-thirds of the spectrum) act to produce each negative, which amounts to the same thing. He proposed to make one negative through an "orange" screen, calculated to absorb the blue light and transmit the red and yellow; one through a "violet" screen, calculated to absorb the yellow light and transmit the red and blue; one through a "green" screen, calculated to absorb the red light and transmit the yellow and blue.

It was no more possible to carry out this idea in Duhauron's way in 1868 than to carry it out in Collen's way in 1865, although Duhauron, having succeeded in making

* *British Journal of Photography*, October 27, 1865, p. 547.

* Class xviii., sec. 3, serial No. 83,061

photographs by exposing ordinary photographic sensitive plates through glasses that were orange, green, and violet to the eye, imagined that he had succeeded in carrying it out. In reality, the photograph made through an "orange" screen must have been made chiefly by either the green, the yellow-green, or the ultra-violet spectrum rays, as can readily be proved by photographing the spectrum itself through a bright orange screen (not an orange-red one), on such a plate as he used. The photograph made through a "green" screen, that transmitted freely both the yellow and the blue rays, must have been made chiefly by the blue rays, and the photograph made through a "violet" screen must have been made without any action by the red rays, and with a great deal by the invisible ultra-violet rays.

Soon after Duhauron published the details of his process, Charles Cros, of Paris, published another modification of Collen's idea.* Like Collen, Cros proposed to make one negative by the action of red light, one by yellow, and one by blue; but by exposing the sensitive plates through red, yellow, and blue glasses, instead of employing plates sensitive to the single colours only. Instead of superposing the respective pairs of these negatives to make each colour print, he proposed to make a green print from the negative made by red light, a violet print from the negative made by yellow light, and an orange print from the negative made by blue light. Cros's plan was free from the defect of doubling intensity on those parts of the negatives representing pale or uncoloured objects; but the advantage gained in this way would be lost again in the production of green, violet, and orange-coloured prints.

The principle of colour selection advocated by Duhauron is identical with that distinctly proposed by Collen, to whom alone the credit of the original invention appears to belong; but Duhauron and Cros, besides proposing a more reasonable plan for obtaining the negatives, further suggested that optical superposition of positive images from the three negatives might be substituted for the superposition of transparent coloured prints.

On December 3rd, 1869, M. Poirée, of Paris, in a communication to the Photographic Society of France,† suggested that better results might be had by making a greater number of negatives—a separate negative for each spectrum region.

* Described in *Photographic News*, October 8, 1869, p. 483.

† *British Journal of Photography*, 1870, p. 26.

In 1873, Dr. H. W. Vogel, of Berlin, discovered that bromide of silver can be made sensitive to the less refrangible spectrum rays by treatment with certain dyes; and this, with the subsequent discovery of other and better colour sensitisers, supplied the means for carrying out either Collen's or Poirée's idea. Duhauron, one of the first to avail himself of these discoveries, made some practical progress, and, in 1876, abandoned Brewster's colour theory and patented a modified process,* based upon the observation that, while there appeared to be "seven" principal spectrum colours, three colouring substances would "serve to express them." The colouring substances he named for this purpose are blue, carmine, and yellow; and he decided that, in order to make such a process reproduce the colours of nature, the negatives should still be made through orange, green, and violet glasses.

At this period, Duhauron's orange-screen negatives were made on chlorophyl plates, and must have been made chiefly by the red spectrum rays. In 1878,† he announced that he had substituted eosine for chlorophyl, so that he must finally have made them chiefly by the greenish-yellow spectrum rays. The significance of this fact has not been generally recognised. The production of three negatives, one through an "orange" screen, one through a "green" screen, and one through a "violet" screen, is a very indefinite procedure. A negative may be made through an "orange" screen chiefly by the action of red rays, or orange rays, or yellow rays, or yellow-green rays, or green rays, or ultra violet rays, according to the character and intensity of the "orange" colour of the screen and the method of sensitising the photographic plate for colour. Duhauron, who never recognised the necessity of testing his process by photographing the spectrum itself, not only did not find out what it is necessary to do in order accurately to reproduce the natural colours, but at different times he did very different and inconsistent things without himself knowing that he did so. The facts can very readily be demonstrated by first showing the spectrum absorption of various "orange," "green," and "violet" screens, and then photographs of the spectrum which

* British patent, July 22, 1876, No. 2,973.

† "Traité Pratique de Photographie des Couleurs," Paris, 1878; *Photographic News*, 1878, p. 115.

have been made on plates differently sensitised for colour. I shall now proceed to demonstrate this point.

In 1879, Cros* also abandoned the idea that red, yellow, and blue are primary spectrum colours, but held that there are three primary spectrum colours and mixtures thereof, and that these primary colours are orange, green, and violet. Like Duhauron, he decided to make negatives through orange, green, and violet screens, and prints in blue, carmine, and yellow. Cros, like Duhauron, was apparently ignorant of the fact that very different negatives can be produced through one and the same screen, and he also allowed all of the invisible ultra-violet rays to act in producing the negative of the "violet" screen.

In 1885, Dr. H. W. Vogel† proposed to make the colour-prints with dyes identical in spectrum absorption with the colour-sensitisers employed in making the negatives. This does not amount to a principle of colour selection, because the entire spectrum can be photographed on plates sensitised with dyes that cannot be combined to reproduce some colours, and even without any dye at all, by the use of suitable colour-screens.

Some time previous to 1889, I do not know the exact date, the Young-Helmholz theory of colour vision was first recognised in connection with this subject, by Dr. F. Stolze, of Berlin.‡ He said, "Although the colours correspond with certain external processes in nature, there is also no doubt that colour as such is nothing objective, but a subjective sensation, based upon the peculiar irritation of the visual nerves by those external proceedings. We can, therefore, only hope to produce a picture in natural colours, when we are enabled to reproduce upon the same the proceedings which furnish to us the colour impression." "Thomas Young . . . assumes that there are three kinds of nerve fibres, sensible to red, green, and violet. Objective homogeneous light excites all three; but with red the first is excited strongly, the second and third weakly; with blue, the second and third moderately strong, the first weakly; with violet finally, the third strongly, and the first and second weakly. If all three kinds of nerves are equally strongly excited, the impression of white light will take place." Dr. Stolze suggested, but rather indefinitely, a procedure which, although not really representing the application of this theory, was more nearly consistent with it than were any of the older ones. The theory itself was defective as a basis of procedure, Clerk Maxwell having shown that the fundamental red sensation is not at all excited by the blue-green, blue and violet rays, the fundamental green sensation not at all by the red or violet rays, and the violet sensation not at all by the red, orange, or yellow rays.

* Bulletin of the French Photographic Society, 1879, p. 23.

† *Annalen der Physik* (N.S.), xxvii., p. 130; *Photo. News*, 1887, p. 568.

‡ *Anthony's Photographic Bulletin* (N.S.), 1888, pp. 516, 555, 588, 647, 678.

It was at this stage that, after ten years of experiment along the same lines as Duhauron, Cros, and Stolze, I myself made certain improvements, and claimed the credit of bringing order out of chaos, by devising a procedure which not only recognises the facts which support the modern colour theory, but which definitely represents the application of that theory.

This process, although in a general way somewhat similar to those which preceded it, really represents a distinctly new principle, which is that of making three photographs by the action of light rays as they excite the three fundamental colour sensations, and superposing these photographs by means of lights or in transparent pigments which suitably represent the corresponding fundamental colour sensations.

In February, 1888, I demonstrated, at the Franklin Institute, Philadelphia,* a process in which the colour selection was according to a definite plan, and proved by photographing the spectrum itself, adjusting the colour screens to obtain definite density curves in the spectrum negative. This was the first publication in which a really definite mode of procedure was indicated; but it was not until November of the same year† that I demonstrated the method so modified as to definitely represent the application of the Young-Helmholtz colour theory, in accordance with Maxwell's measurements of the relative power of different spectrum rays to excite the respective fundamental colour sensations.

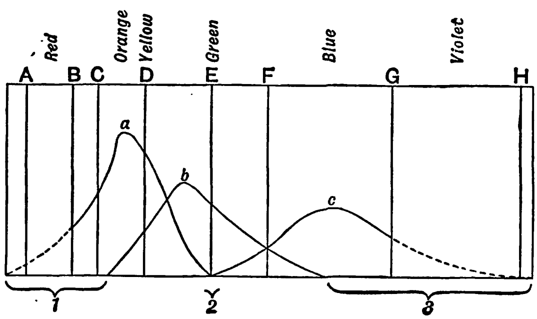
A little study of Maxwell's diagram, showing the result of his measurements, will show that the application of this new principle involves very important departures from the older methods of procedure. In this diagram, which I reproduce, 1, 2, 3 are spectrum colours which represent fundamental colour sensations, because each excites one sensation only, and

* *Journal of the Franklin Institute*, cxxv., 345.

† *Journal of the Franklin Institute*, Jan., 1889.

a, *b*, *c* are curves showing the relative power of different spectrum rays to excite the respective fundamental colour sensations.

The first remarkable fact to be gathered from the study of this diagram is, that the rays which represent a fundamental colour sensation are in no case the ones that most powerfully excite that sensation. The red sensation is excited by all the spectrum rays from red to green, but most powerfully by the orange; and the negative to represent the effect upon the fundamental red sensation must therefore be made, not through a red glass, or by the red rays, but by the joint action (in definite proportions) of the red, orange, yellow, and yellow-green spectrum rays. The negative to represent the effect upon the green sensation must be made by the joint action of the orange, yellow, yellow-green, green, and green-blue spectrum rays, in proportion to their power to excite that sensation. The



MAXWELL'S DIAGRAM.

negative to represent the effect upon the blue-violet sensation must be made by the joint action of the blue-green, blue, and violet spectrum rays, in proportion to their power to excite that sensation.

By photometric measurement of the density curve of a spectrum negative, the relative amount of action by the different spectrum rays may be found. It is, therefore, only necessary, in order to secure action by different rays in any definite proportions, to use such a combination of sensitive plate and colour screen as will yield a spectrum negative having a density curve corresponding to the graphic curve representing such proportionate action.

Sensitive plates and colour screens that will yield three negatives of the spectrum, having intensity curves like the three graphic curves in Maxwell's diagram, will produce a permanent photographic record of the effect of light from any object upon the three fundamental colour sensations. This can most readily be accomplished (with separate plates) by exposing a cyanine-stained rapid gelatine-bromide plate through a double screen of aniline yellow and chrysoidine orange, of suitable intensity, for the red sensation; a commercial "orthochromatic" plate through a screen of "brilliant" (aniline) yellow, of suitable intensity, for the green sensation; and an ordinary gelatine bromide plate through a very thin piece of plane polished green glass for the blue-violet sensation. The screens that will secure the same results all on one kind of plate are far more complicated and difficult of adjustment; but anyone who possesses a photospectrograph and a good assortment of coal-tar dyes can, by the exercise of some skill and ingenuity, make the adjustments for himself.

The set of three photographs of any object, made as I have indicated, of course show no colour whatever; but they contain, in a permanent form, such a graphic record of the natural colours that, in order to reproduce them to the eye, it is only necessary to superpose the three positive images, either upon a screen, or upon the retina of the eye—the one representing the red sensation with pure red light, the one representing the green sensation with pure green light, and the one representing the blue-violet sensation with blue-violet light. The blending of the three images will excite exactly the same sensations as the light coming directly to the eye from the object itself. The synthesis can also be made with superposed transparent colour-prints, and this is the plan which has received the most attention, although the simplicity of *optical* superposition commends it to scientists, and is really more convincing to everybody.

Both Duhauron and Cros had the idea of synthesis by optical superposition as well as by colour-prints, but neither of them succeeded in carrying out the idea practically. Superposition by triple optical lantern projection was first carried out successfully by me, in my demonstration at the Franklin Institute, Philadelphia, in February, 1888, showing a landscape photographed from nature. I employed a single lantern-box, having three optical systems close together, with a triple lime-light jet, and the three positives mounted side by side in a single wooden frame, behind red, green, and blue glasses. A considerable variety of subjects were shown with the same lantern in November

of the same year, when I first clearly stated and demonstrated the principle which represents the application of the Young-Helmholtz-Maxwell colour theory.

The first workable plan of optical superposition other than by lantern projection was devised by Antoine Hippolyte Cros, brother of Charles Cros, and patented in 1887. In this device, the three pictures are arranged relatively to each other like the steps of a staircase, aud by means of a peculiar system of mirrors, some of which are attached to the face of a rapidly revolving wheel, with open spaces between them, the different pictures are seen by the eye in one optical plane, in such rapid succession, that they appear like a single picture, with colours blended. The same device, which is a very ingenious one, was to be used also for making the negatives; but it is so clumsy. so troublesome, by reason of the necessity for providing means to keep the mirrors in motion, and includes such an extremely narrow angle of view, that I believe it has no practical value.

Both Duhauron and Cros taught that synthesis by optical superposition should be accomplished with the same mixtures of l ght rays that acted to produce the different negatives. The picture made through an orange screen was to be seen by the light transmitted by the same, or an exactly similar screen, and so on.

I hope I have made it clear that such a procedure is quite irrational, in view of the facts which support the Young-Helmholtz-Maxwell colour theory. The photograph made by the joint action of various different colours of spectrum rays must be seen by rays of one colour only. Spectrum rays of various colours excite one fundamental sensation, but only spectrum rays of one single colour will serve to represent that fundamental sensation.

I have taken particular pains to emphasise this fact in every paper I have published upon this subject, but have not yet succeeded in impressing it upon the minds of the French writers, who continue to assert that my procedure does not differ in any essential particular from that indicated by Duhauron and Cros. I think that this one difference alone is of vital importance.

The application of the Young-Helmholtz-Maxwell theory involves important changes from the older methods, not only in the negative process, and in the synthesis by optical superposition, but also in the production of permanent colour-prints. Theoretical considerations alone led me to conclude that a transparent colour-print from either negative could be made to perform exactly the same function that the positive transparency from the same negative performs in the synthesis of triple-lantern projection, and a simple experiment with the triple lantern confirms my conclusions.

The white disk that we obtain in screen projection by mixing the red, green, and blue-violet lights, corresponds to the white paper which may form the basis of a permanent colour-print heliochrome. When we insert the positive of the red sensation in its place in the lantern, its shadows cut off the red light, leaving the disk still white except in the shadows, where there remains only a mixture of the other two lights, green and blue-violet; a transparent print from the same negative performs the same function when laid upon the white paper, provided that its shadows also cut off the rays that excite the fundamental red sensation, but freely transmit the green and blue-violet. I have found that a coal-tar dye, sold as "thio blue A," absorbs those rays which excite the fundamental red sensation, but freely transmits the green and blue-violet; a Woodburytype process print in this colour fulfils the requirement for a permanent print to represent (by transparency) the effect upon the fundamental red sensation. By a similar process, I have found that fuchsine fulfils the requirement for making a print to represent the green sensation, and aniline-yellow the print for the blue-violet sensation. It is true, as I have already pointed out, that these permanent colour-print heliochromes will show a slight degradation of colour in ordinary white light, but they should exactly reproduce the natural colours when viewed in a white light produced by mixing the red, green, and blue-violet spectrum rays.

The theoretical conditions of success have, therefore, been realised for the negative process, and for all three methods of synthesis.

But there is another aspect of this subject which, from a practical and commercial point of view, is quite as important as that of realising the theoretical conditions of success. I am of the opinion that, however perfect results this process could be made to give, it would not be reasonable to expect it to be commercially successful, so long as complicated by the necessity for making three separate photographic negatives and three separate photographic colour-prints, in order to obtain a single reproduction in colours. Such a complicated procedure might be

carried out successfully by experts, dealing with such subjects as paintings or similar art objects, but would not be available for landscape photography, or in the hands of amateurs.

The only way to make the process simple and reliable enough to be available generally, is to reduce the number of negatives to one, and dispense with the colour print process altogether. This I have accomplished by the invention of a camera that makes the three pictures on a single plate, by one exposure from one point of view, and a device, which I have named the heliochromoscope, that optically recombines the triple black and white photograph into a single photograph reproducing the natural colours. With this camera (about the size of a kodak) and the heliochromoscope (the size of a hand stereoscope), the reproduction of the natural colour by photography is not only made practically available, but reduced to the simplicity of stereoscopic photography.

I wonder if people are prepared to realise the full significance of this fact. The hope of producing colour *prints* by a direct process, is calculated to discredit the value of an equally simple method that accomplishes substantially the same result in a different way. I said, "substantially the same result," but, in a way, it is a better result, because it is quite impossible than any coloured picture, with its distracting surroundings and surface reflections, should ever produce such a perfect illusion of nature itself as we may obtain with this little instrument, consisting of several small mirrors, two of them transparent, placed at certain angles with reference to the photograph, and inclosed in a box. If the heliochromoscope was merely a box for seeing photographs in colours, it might be regarded with indifference; but I hold that it is as far from being merely that as the phonograph is from being merely a device for making a noise by turning a handle. It is capable of accomplishing for us, in the reproduction of colours, more than the phonograph accomplishes for us in the reproduction of sounds, because the illusion is more perfect. I quite believe that the writer who, in a recent article in *The Speaker*, described the heliochromoscope as a toy, comparable to the kaleidoscope, would have been capable, under similar circumstances, of comparing the phonograph to a baby's tin rattle.

I have also tried to simplify and perfect the colour-print process. The employment of the new triple camera, making one operation take the place of three, is one step in that direction. The use of the dyes I have mentioned, corresponding to the colours produced in screen demonstration, is another. The production of a single print instead of three, cutting the images apart only when ready to be dyed, is another. Experiment with the Woodburytype process is another. The Woodburytype process offers the vitally important advantage for reproduction in large numbers that, having found experimentally the right amount of dye required in each of the three colour-prints, an indefinite number can be made without any variation; it will be available for the commercial production of lantern slides. These appear to be real advances; but, after all, the further complication and mechanical difficulties of carrying out the print making process, render it comparatively unsatisfactory up to the present time—and the value of composite heliochromy must be estimated, for the present, on the basis of its application to the photographic reproduction of the natural colours by optical superposition.

If the heliochromoscope is the only solution of the problem that is sufficiently simple to be practicable for general introduction, there is, nevertheless, a field for the application of the method of colour projection for lecture illustration. Here, also, we escape the complication and mechanical difficulties of colour printing, and obtain results which are permanent as far as the colour record goes, and which can be shown to many people at one time. It will be necessary, however, to employ the arc electric light in order to project landscape views at night as perfectly as they have already been projected by sunlight. The value of the method cannot be fully demonstrated with the lime light.

In conclusion, I would like to say another word to emphasize the fact, which I think is quite sufficiently demonstrated in the heliochromoscope, that although we are not able to make photographs in natural colours of exactly the kind that people have been looking for, we have, nevertheless, found a true solution of the problem of reproducing the natural colours by photography, as remarkable in its results as the telephone or phonograph, more perfect in the illusion of nature than would be possible in coloured pictures, and almost as easy to realize as stereoscopic photography. It seems to me that this is an advance so great that it should finally break down the prejudice against the idea of composite heliochromy which has

grown out of the long series of failures of unscientific, complicated, and impractical methods. With no more operations than are required to make an ordinary photograph, we now make a photograph that, as we are able to see it, reproduces nature itself, light, shade, and colour.

DISCUSSION.

The CHAIRMAN said photography in natural colours, as generally understood, was something different from what Mr. Ives had now shown. What had been wished, but hardly hoped for, was a photograph in which all the colours of nature would be reproduced on one plane surface, in one picture, directly in the camera, and by one print. Mr. Ives had not given them the whole loaf, but he had produced something which might perhaps be esteemed a good half of it. He had shown some very beautiful results, and had explained the means and the principle on which they have been produced with singular clearness and precision. He had shown that in the production of the photographs to form the basis of colour photograph combination, not only had the character of the sensitive surface to be considered in photographing the radiations from particular colours, but also the screen to be combined with a particular quality of colour-sensitivness in the plate, and that the separate consideration of either screen or sensitive plate was useless. Mr. Ives's teaching and procedure in relation to the production of negatives for the production of colour photographs were applicable not only to the kind of pictures he had shown that evening, but also threw a strong light on the principles to be followed in copying paintings and coloured objects generally, with a view to rendering in correct monochrome all the different values of the colour in the oil painting. He conceived that to be a very useful application of the principles now explained.

Professor ROBERTS-AUSTEN, F.R.S., wished to express his appreciation of the extreme ingenuity displayed in the construction of the camera, and in arranging these marvellous optical effects which had been shown. He had had the privilege of visiting Yellowstone-park, and could bear testimony to the extraordinary fidelity with which the marvellous colour effects there seen had been reproduced.

Mr. B. FRANCIS COBB said there was very little room for discussion; they had simply to listen and learn, and admire the extraordinary results Mr. Ives had obtained. It had frequently been said that if ever colour photography was to be achieved, it would be by some means at present little suspected, or by some totally new appliance. Mr. Ives was certainly opening the way to what in future might lead to very great results, and he (Mr. Cobb) could only hope that Mr. Ives would continue the researches which all were watching with the greatest interest, and that later on he would come before them again with still further advances.

Mr. VAN DER WEYDE asked if anything had been done in the way of portraiture by this method. He apprehended the exposure would have to be prolonged, and the light very strong, so that perhaps the sitter would have to close his eyes during the operation.

Mr. WILLIAM H. WARD said he had had the opportunity, last winter, of seeing, in Mr. Ives's own house in Philadelphia, several of the pictures now shown, and he could say that when displayed by sunlight they were quite fifty per cent. better. That would give some idea of the improved effect which would be obtained with a lantern fitted with an arc light.

Sir HENRY TRUEMAN WOOD said it would be interesting if Mr. Ives could give some further information as to the way in which he regulated the exposure for each of the three pictures produced on the same film. As he understood, they were all produced simultaneously on one film and developed at the same time, and consequently the amount of exposure for each must be carefully regulated. It was obvious that the picture produced by the red rays must require a very much longer exposure than the one produced by rays of higher refrangibility; it would be interesting to know how it was done. One could understand that it might be regulated by varying the size of the aperture, or by other means. A great deal of credit was due to Mr. Ives for the extreme ingenuity with which he had rendered practically useful a method which had been in the minds of a great many people for a long time, and which had been accomplished, with a varying amount of success, by previous experimenters. But Mr. Ives had certainly achieved in this particular direction a very distinct success. The practical application of it had yet to be seen, though it was not difficult to see that it had many possibilities of usefulness.

The CHAIRMAN said he should like to know what kind of plate was most suitable for taking these negatives, and whether Mr. Ives had a preference for one particular kind of plate rather than another.

Mr. IVES in reply, said he thought a special plate should be manufactured for this work, slightly modified from anything now on the market, but in order to make the operation sufficiently easy and convenient he had adopted commercial orthochromatic plates; the results shown were all obtained with commercial plates manufactured by Messrs. Carbutt of Philadelphia. The one picture which would be seen in the heliochromoscope, a bouquet of English flowers, was taken on an Edwards' isochromatic plate, which was very similar, There were two methods of securing simultaneous equal exposure for three pictures,

the plates not being anything so sensitive to red as to the other colours. If the three pictures were taken at one exposure through a single lens, the ray being divided after it passed through the lens, he had a number of ground and smoked glasses of different degrees of density, and having adjusted the colour screen to give the density grades he wanted in the spectrum negative, he inserted one or more smoked glasses until he found three pictures developed together after the same exposure. He had another camera in which the pictures were taken on one film by three separate lenses, and in that case the diaphragms were varied; that for the red being much larger than that for the other two. It would be possible to take a portrait by this process now, but it would require an exposure of three or four minutes in a strong light. Plates could be specially prepared which would reduce the exposure in a strong light to possibly 15 or 20 seconds, but inasmuch as the process was not practically available for portrait-work at present, he had not troubled himself with experiments in that direction.

The CHAIRMAN then proposed a vote of thanks to Mr. Ives, which was carried unanimously.

INDIAN SECTION.

Thursday, May 19, 1892; Sir CHARLES BERNARD, K.C.S.I., in chair. The paper read was "The Administration of the Imperial Census of 1891 in India," by JERVOISE ATHELSTANE BAINES, I.C.S., Chief Census Commissioner for India.

The paper and report of the discussion will be printed shortly in the *Journal.*

FOREIGN & COLONIAL SECTION.

Tuesday, May 24, 1892; the Hon. JAMES MONRO in the chair. The paper read was "The Extension of Colonial Trade," by Colonel HOWARD VINCENT, C.B., M.P.

The paper and report of the discussion will be printed shortly in the *Journal.*

Miscellaneous.

IRRIGATION IN SYRIA.

The United States Consul at Beirout says that, generally speaking, the character of the irrigation works in Syria is of the most primitive kind. From rivers the conveyance of water is usually by means of canals or rough ditches, badly levelled and aligned, often without masonry, except at the intake, the weirs being re-made every season of boulder, stone, and brushwood, rarely over three feet high. Irrigation from springs is generally much the same as from the rivers, though necessarily on a smaller scale. From wells the system universally adopted is that of the "Na'hura." The "Na'hura" is of the simplest construction, cheap, quickly made and repaired, and easily worked, while it raises a comparatively large quantity of water. Its construction consists of a clumsy cog-wheel fitted to an upright post, and made to revolve horizontally by a donkey, mule, or horse attached to the sweep; this turns a similar one perpendicularly placed at the end of a heavy beam, which has a large wide drum built into it directly over the mouth of the well. Over this drum revolve two rough hawsers or thick ropes, often made of myrtle twigs and branches twisted together, and upon them are fastened small earthen jars or wooden buckets. One side descends while the other rises, carrying the small buckets with them; those descending are empty, while the ascending ones are full, and, as they pass over the top, they discharge into a trough which conveys the water to the cistern. The length of the hawsers and number of buckets depend upon the depth of the well; for the buckets are fastened to the hawsers about two feet apart. The wells are of different depths, but generally average from 10 to 12 feet. It is claimed that, with good animal power, two gallons of water can be raised every second. The "Shaduf," so conspicuous on the Nile, is not used in Syria, but on the shores of Lake Tiberias an apparatus much like it has been seen at work, and the well sweep and bucket is also met with in many places. Another method may be observed on the plains of central Syria. It consists of a large buffalo skin, so attached to cords that, when let down into the well, it opens, and is instantly filled, and, being drawn up, closes up, so as to retain the water. The rope by which it is hoisted to the top works over a wheel, and is drawn by donkeys, mules, oxen, or camels, which walk directly from the well to the length of the rope, and then return, only to repeat the process, until a sufficient quantity of water is raised. The wheel and bucket, of different sorts and sizes, are much used, where the water is near the surface, and also along rapid rivers. For shallow wells, merely a wheel is used, whose diameter equals the desired elevation of the water. The rim of this wheel is large, hollow, and divided into compartments, filling the place of buckets. A hole near the top of each bucket allows it to fill, as that part of the rim in revolving dips under the water. This, of course, will be discharged into the trough, when the bucket begins to descend, and thus a constant succession of streams falls into the cistern. The wheel itself may be turned by donkeys, mules, oxen, or camels. Small water-wheels are sometimes turned by feet, but the process is tedious, toilsome, and not productive of much result. At Homs, in the Tripoli district, there is a lake or artificial basin of about four

thousand acres in extent, formed by draining the Orontes river. It is very shallow in summer, probably not over ten or fifteen feet at the deepest part, but will reach a depth estimated at from thirty to forty feet in the winter. The lake was made for the double purpose of regulating the summer flow of the Orontes and for obtaining sufficient water to irrigate the extensive gardens of Homs. This lake is the only artificial system of irrigation on a large scale in the country, but it is not kept in very good repair. The Pools of Solomon, at Tyre, may also be mentioned. They are natural artesian wells of great volume, irrigating some fifteen hundred acres of garden land by artificially raised conduits.

THE MANUFACTURE OF PAPER IN COREA.

The United States Consul-General at Seoul, in his last report, says that paper manufacture is one of the leading industries of Corea. This paper is highly esteemed, and always forms part of royal presents, and of the tribute paid to China. Besides its use for writing and for books, it is employed in a great diversity of ways. It serves as string, and in the manufacture of lanterns, fans, umbrellas, shoe soles, hats, boxes, and coats. It is also used for covering floors, walls, and ceilings, and, stretched on frames, supplies windows and doors. It is highly prized in China and Japan, and is especially sought after for the manufacture of umbrellas. It is made from the bush of the mulberry order (*Broussonetia papyrifera*), which is indigenous, growing in many parts of the kingdom, but thriving best in the moist, warm climate of the south. It is chiefly grown from cuttings for this especial purpose, and the wild and cultivated plants are said to be of equal value. The bark, which alone is used, is generally gathered in the spring, and it is boiled for a long time in water, in which a quantity of wood ashes has been mixed, until it becomes a pulp, the mass having been beaten during the whole time of the boiling. Fine bamboo screens are then placed in shallow wooden vats, and a ladle full of the pulp is evenly spread over the screen by a dexterous circular motion of the hand. This operation is repeated once or twice, or as often as may be necessary—the more frequent the operation, the finer the paper—and the screen allowed to drain into the vats, until a proper consistency is reached, the drippings being thus saved. They are placed on a hot *kang* floor to dry. After the drying has proceeded far enough, the paper is laid on a hot floor, and ironed by hand. The long lines in the paper show strands of the bamboo screens, and their nearness, distinctness, or absence indicate the fineness or otherwise of the paper. They are almost imperceptible in some grades of paper, while in others they are distinct and far apart. Paper is made by the Paper Guild, a numerous and prosperous association. The province of Chulla is the chief seat of manufacture.

VITICULTURE IN BOSNIA AND THE HERZEGOVINA.

Her Majesty's Consul-General at Serajevo says that the Austrian Government is paying great attention at the present time to the cultivation of the vine in Bosnia and Herzegovina, and to the making of wine in these provinces. More than a year ago the tithe on wine, which, as well as the tithe on grapes, had till then been levied, was finally abolished, and even vineyards planted on hitherto unproductive ground were exempted from the grape tithe for the first ten years. Two horticultural stations have been established—one at Dervent, in the north of Bosnia, and the other at Mostar, in the Herzegovina; at the former of which about 37 acres, and at the latter 24 acres, have been laid out in vineyards. Not only can the inhabitants receive at these stations practical instruction in the culture of the vine, but, as far as possible, they are furnished from them with cuttings to plant new vineyards. At Mostar there is also a wine press, and the peasants can, therefore, learn the most improved methods of making and storing wine. The climate and soil of a great part of the Herzegovina, and more especially the districts of Mostar, Konjica, Ljubuski, Ljubinje, Stolac, and Trebinje, are eminently suited to the growth of the vine, whereas the climate of Bosnia appears to be too cold and the summer too short, except in the valley of the Save, for the grapes to reach full maturity. In Bosnia there are not more than about 620 acres laid out in vineyards, while in the Herzegovina at least 12,000 acres are devoted to the cultivation of the vine. The descriptions chiefly cultivated are of native origin. The red grapes are known by the name of *Blatinica*, and the white by that of *Zelenka*, and both are considered very good for the table. Some vines have also been brought as an experiment from Burgundy, and others from Kecskemeter in Hungary. The total annual yield of grapes in the two provinces is estimated at from 8,000 to 9,000 tons. A very large proportion of these grapes are eaten in the country, a certain quantity are exported to Austria Hungary for the table or for manufacture of wine, and the remainder are made into wine on the spot and consumed in the province. This native wine is prepared in a very primitive way and with little care, the white and red grapes being generally mixed together. It is, therefore, not of very good quality and does not keep well. In colour and flavour it much resembles the wines of Dalmatia, but contains less alcohol. The wholesale price of wine in the Herzegovina after last year's vintage, which was an abundant one and the grapes of excellent quality, was from 30 to 35 florins per hectolitre (from £2 10s. to £2 18s. per 22 gallons). The phylloxera has not yet made its appearonce in Bosnia or the Herzegovina, and the peronospera, which has been very prevalent of late years, appears, owing to the dryness of the season and the measures taken by the Government to combat it, to have done but little injury in 1891.

Notes on Books.

THE OPTICS OF PHOTOGRAPHY. By J. Traill Taylor. London: Whittaker. 1892.

Since the publication of "Monckhoven's Photographic Optics"—a work of practical value, though in places inaccurate, and now to a large extent obsolete—no writer seems to have dealt specially with the important subject of photographic lenses. Descriptions of many of the special arrangements of lenses used for photographic purposes are given in photographic text-books, and of course all treaties on optics deal, at least theoretically, with the subject of lenses generally. There does not, however, appear to be any book which will give the now numerous students of photography at once that elementary knowledge of scientific optics they ought to possess, and that practical information about the instruments they are using which is essential to their proper use. This want Mr. Taylor has undertaken to supply, and his long familiarity with the subject renders him admirably well qualified for the work. The photographer will find here to his hand a general description of the principles on which his lenses work, the method of their construction, their defects and the means for remedying or diminishing them, directions for testing of lenses, and descriptions of the various classes of lenses old and new, together with much other information all of a thoroughly practical nature.

"BLACK AND WHITE" HANDBOOK TO THE ROYAL ACADEMY AND NEW GALLERY PICTURES, 1892: with Biographies and a Brief History of the Royal Academy, by C. Lewis Hind. London: "Black and White."

This volume contains nearly one hundred and fifty pages of engravings of the principal pictures in this year's Exhibition of the Royal Academy, and prefixed is an account of the Academy, and portraits and short notices of all the Royal Academicians and Associates.

MEETINGS OF THE SOCIETY.

APPLIED ART SECTION.

Tuesday evenings, at Eight o'clock:—

MAY 31.—WILLIAM DE MORGAN, "Lustre Ware." Sir GEORGE BIRDWOOD, K.C.I.E., C.S.I., will preside.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, MAY 30 ... Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Mr. J. A. Nettleton, "Manufacture of Vinegar." 2. Dr. S. Rideal, "The Petroleum Jellies of Commerce." 3. Dr. C. R. A. Wright, "Certain Aluminium Alloys."
Surveyors, 12, Great George-street, S.W., 3 p.m. Annual General Meeting.
British Architects, 9 Conduit-street, W., 8 p.m.

TUESDAY, MAY 31...SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. (Applied Art Section.) Mr. W. De Morgan, "Lustre Ware."
Royal Institution, Albemarle-street, W., 3 p.m. Prof. R. C. Jebb, "Some Aspects of Greek Poetry." (Lecture II.)
Central Chamber of Agriculture (at the HOUSE OF THE SOCIETY OF ARTS). 11 a.m.
Civil Engineers, 25, Great George-street, S.W., 8 p.m. Annual Meeting.
Royal Scottish Geographical Society, 20, Hanover-square, W. 8½ p.m. (London Branch.) Mrs. Bishop (Isabella L. Bird), "A Journey through Lesser Tibet."

WEDNESDAY, JUNE 1 ... East India Association, Westminster Town Hall, S.W. 2½ p.m. Surgeon-General Sir William Moore, "The Opium Question."
Entomological, 11, Chandos-street, W., 7 p.m.
Archæological Association, 32, Sackville-street, W., 8 p.m.
Obstetrical, 20, Hanover-square, W. 8 p.m.

THURSDAY, JUNE 2...Royal, Burlington-house, W., 4½ p.m.
Antiquaries, Burlington-house, W., 8½ p.m.
Linnean, Burlington-house, W., 8 p.m. 1. Mr. E. A. Floyer, "The Disappearance of Desert Plants in Egypt." 2. Mr. F. H. Perry Coste, "Insect Colours." 3. Lantern Demonstration.
Chemical, Burlington-house, W., 8 p.m. Prof. R. Meldola and Mr. F. W. Streatfield, "Ethylene Derivatives of Diazo-amido Compounds."
Society for the Encouragement of Fine Arts, 9, Conduit-street, W., 8 p.m. Mr. R. A. Sterndale, "Cyclopean Architecture in Polynesia."
Royal Institution, Albemarle-street, W., 3 p.m. Mr. R. G. Moulton, "Faust." (Lecture II.)
Manchester Geographical Society, 44, Brown-street, Manchester, 8 p.m. Rev. L. C. Casartelli, "Commerce in Relation to Geography."
Camera Club, Charing-cross-road, W.C., 8 p.m., Mr. A. F. Stanley-Kent, "Practical Photo-Micrography."
Archæological Institution, Oxford-mansion, Oxford-street, W., 4 p.m.

FRIDAY, JUNE 3 ... Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting, 9 p.m. Mr. Ludwig Mond, "Metallic Carbonyls."
Geologists' Association, University College, W.C., 8 p.m. Mr. F. W. Rudler, "The Fathers of British Geology."
Philological, University College, W.C., 8 p.m.
Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.
Physical, Science Schools, South Kensington, S.W., 5 p.m. Prof. O. J. Lodge, "On the Present State of our Knowledge of the connection between Matter and Ether. An Historical Summary."

SATURDAY, JUNE 4...Royal Institution, Albemarle-street, W., 3 p.m. Prof. H. Marshall Ward, "Some Modern Discoveries in Agricultural and Forest Botany." (Lecture II.)

The Telegraphic Address of the Society of Arts, and of the Royal Commission for the Chicago Exhibition, is "Praxiteles, London."

Journal of the Society of Arts.

No. 2,063. Vol. XL.

FRIDAY, JUNE 3, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

ALBERT MEDAL.

The Council of the Society of Arts have, with the approval and sanction of the President, H.R.H. the Prince of Wales, awarded the Albert Medal to Thomas Alva Edison, "in recognition of the merits of his numerous and valuable inventions, especially his improvements in telegraphy, in telephony, and in electric lighting, and for his discovery of a means of reproducing vocal sounds by the phonograph."

CONVERSAZIONE.

The Society's *conversazione* is fixed to take place at the South Kensington Museum (by permission of the Lords of the Committee of Council on Education) on Wednesday evening, June 29th.

Each member will receive a card for himself, which will not be transferable, and a card for a lady. No tickets will be sold.

Further particulars as to arrangements will be announced in future numbers of the *Journal.*

Chicago Exhibition, 1893.

MEETING OF THE ROYAL COMMISSION.

A meeting of the Royal Commission was held on Wednesday, 1st inst. Present: The Attorney-General, M.P., Q.C., in the chair; Sir Frederick Abel, K.C.B., D.C.L., D.Sc., F.R.S., Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., Sir Edward Birkbeck, Bart., M.P., Major-General Sir Owen Tudor Burne, K.C.S.I., C.I.E., Michael Carteighe, Francis Cobb, Sir Philip Cunliffe-Owen, K.C.B., K.C.M.G., C.I.E., Major-General J. F. D. Donnelly, C.B., James Dredge, Francis Elgar, LL.D., Sir Douglas Galton, K.C.B., D.C.L., F.R.S., George Matthey, F.R.S., Sir Saul Samuel, K.C.M.G, C.B., with Sir Henry Trueman Wood, M.A., as Secretary.

COLLECTION OF GUIDE BOOKS, &c.

The Royal Commission are forming a collection of Maps, Guide Books, Photographs, Railway and Steamship Guides, Programmes, &c., and other printed matter likely to supply useful information to exhibitors at, and visitors to, the Chicago Exhibition.

The collection is placed in the library of the Society of Arts for consultation by persons interested. It will be open to members of the Society, exhibitors, or their agents, and persons introduced by either of the above.

A considerable number of books, &c., have been collected, but the Royal Commission will be glad to receive any works suitable for the above purpose for addition to the Collection.

Proceedings of the Society.

APPLIED ART SECTION.

Tuesday, May 17, 1892; General Robert Maclagan, R.E., in the chair:—

The paper read was—

MUD, A MATERIAL IN PERSIAN AND EASTERN ARCHITECTURE.

By William Simpson,

R.I., M.R.A.S., Hon.Assoc.R.I.B.A.

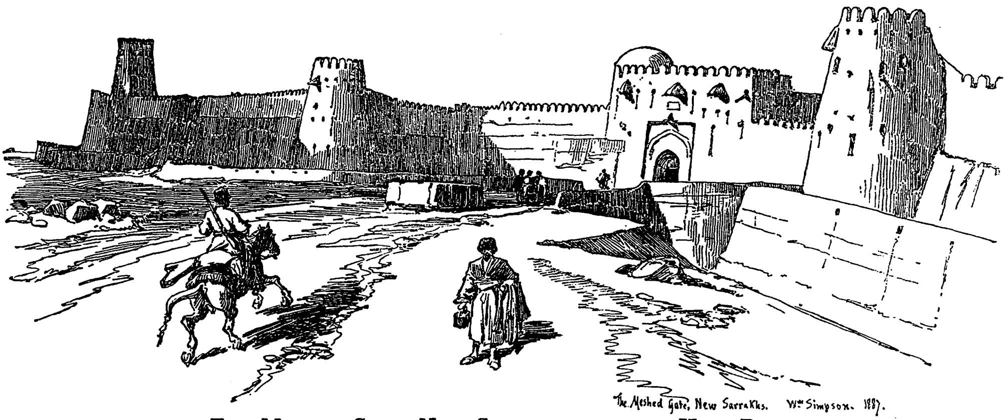
It is necessary to premise that under the term "Mud" I include sun-dried bricks. When bricks have been burnt in the fire, the material becomes entirely changed, and ceases to be mud, so I exclude them from consideration in the present paper as a building material. Wet earth made into blocks and dried in the sun differs in no way from a layer of the same laid on a wall.* Both

* Bricks of this kind, "when placed one upon another after being imperfectly dried, combined, under the influence of the weather and their own weight, into one homogeneous mass so that the separate courses became undistinguishable. This latter fact has been frequently noticed in Assyria, by those who had to cut through the thickness of walls in the process of excavation." Perrot and Chipiez, "A History of Art in Ancient Egypt." vol. i. p. 113.

methods were used in the East, and often combined in the same building. The reason for this is soon found out if you attempt to raise a mud wall. A layer of two or three feet thick must be allowed to dry and consolidate before another is placed on it, because the weight above would press out the soft material below, and the whole would tumble down. In some localities a layer of mud is put down at the commencement, and while that is drying bricks are made to be placed above.

It was during the cold season of 1884-85, in travelling through Persia at the time of the Afghan Boundary Commission, that the importance of mud in connection with building and architecture first attracted my attention. I had to pass from Tehran eastward, through Khorassan, and into Afghan Turkestan.* Along the whole of this route mud is the building material. Some of the serais—that is, caravan serais for the accommodation of travellers, are of burnt brick, but these are about the only exceptions. Not only villages, but large towns are built of mud or sun-dried brick. The defensive walls are of the same material; even such large towns as Sabzawar, Nishapur, Meshed*, and new Sarrakhs, are fortified with walls of this kind. Fire-burnt bricks may have been more frequently used in former times, that was when the country had been more prosperous, and before Turkoman raids began. On the remains of former towns a few fire-burnt bricks† might be seen scattered about, but the great mounds seemed to be composed of nothing but earth, suggesting that these fragments were the exception. On realising this almost exclusive use of one building material, in one region, my mind naturally recalled what I had seen in India; where, although stone and fire-burnt brick

FIG. 1.



THE MESHED GATE, NEW SARRAKHS, ON THE HERI RUD.

are largely used, yet the villages are over very large districts wholly constructed of mud. In Afghanistan it is the same. The Fort at Peshawer, which was Afghan territory up to Runjit Singh's time, is a mud one. Jellalahad is surrounded by a mud wall. From the Khyber Pass to Tehran the towns and their defences, as well as the villages, are almost identical in their material as well as in their general appearance.

These statements show that over a large geographical space in the Eastern world the building material, at the present day, is almost exclusively mud. I have been thus far speaking of what I have seen with my own eyes. To this may be added the practice of other countries. I believe that it is the same over most of Central Asia. It is now accepted that in Mesopotamia it was largely employed; and we know that in Egypt, from the earliest times to the present day, it has been the principal means employed in structural erections. It was largely used in Greece in ancient times, and also in Spain. It was known in South America and all along the Pacific Coast, from

* See paper on "Experiences on the Afghan Frontier," by William Simpson, *Journal of the Society of Arts*, March 26, 1886, where details of the journey will be found.

* The blocks of Figures 1 to 5 and 7 have been kindly lent by the Council of the Royal Institute of British Architects, for use in the illustration of this paper.

† At Kala-i-Maur, on the Khushk, I measured some fire-burnt bricks, which were 11¾ inches square, and the thickest were 2¼ inches thick. Another was 10¾ inches square. There was an oblong brick, 7½ inches long. It looked much like our own bricks, but it was only 1½ inches thick. Perrot and Chipiez state that the ancient bricks in the Euphrates Valley were from 15½ to 15¼ inches square, and from 2 to 4 inches thick. Persian sun-dried bricks are about 8 inches square, and 2 inches thick.

Peru to San Francisco. The word "dobies," for sun-dried bricks, is a familiar term—this is derived from the Spanish word *adobes*.* In 1873, I visited the original church dedicated to St. Francis, and which gave its name to the now well-known town in California—this church was constructed with "dobies." Mud houses were not uncommon in England in the past; and they are yet known in Devonshire, where the stuff they are constructed with is called "cob." I might largely increase this list of localities, but enough has been given to show how extensively mud has been used in the past as well as in the present for building purposes. I am under the impression that its importance in connection with building has hitherto been overlooked. The lithic architecture of Greece having been traced back to wooden forms has led to the study of wood as an early structural material; and up to the present little or nothing has been done with mud.

Owing to this it has been generally assumed that wood supplied the first means by which the primitive man had formed a shelter to himself as a protection from the weather. The Australian native, as he was represented some years ago at the Colonial Exhibition, was a good example of the simple beginnings of wooden architecture; but a very slight consideration will bring to the mind the possibility that the use of mud might, at least, be equally primitive. It would all depend upon where the primitive man found himself; if trees were scarce, or none whatever were to be found, the wetting of earth and raising a wall with it must have been very soon discovered. The children making "mud pies" might have given the first hint. Once begun, the progress of mud architecture would be considerable. Those who began their architectural style with branches of trees could not have made any advance until some kind of implement was invented, by means of which the wood could be cut and fashioned; and the "stone age," when stone tools came into use, is a comparatively late one in man's history. The mud builder, on the contrary, required no tools; his hands were sufficient for every purpose. He may have been content at first with an enclosure formed by four walls. A covering of grass or reeds would soon suggest itself; this, although rude and primitive, would be the first complete human habitation. But more than that, it would be the beginning of the "house"—the "home," which, from the relations and associations it produced, must have been one of the most important steps in the history of early civilisation. This, of course, is only a speculative suggestion as to what took place, but in the nature of the conditions it is a probable one. We find a confirmation of this when we remember that the Nile Valley and Mesopotamia, two preeminently mud building regions, are now noted for their very early civilisation.

The great antiquity of the use of mud as a building material can be established from a number of references to history. Like most things that were important to man in his early condition, this can be traced back even to the mythical period. In Persia, at least, we have traces of it. Firdusi, in the *Shah Namah*, relates how Jemshid, now known as a mythical personage, introduced a better civilisation among the people; among the improvements it is told how, "He taught the unholy Demon train to mingle water and clay, with which, formed into bricks, the walls were built, and then high turrets, towers, and balconies, and roofs, to keep out rain, and cold, and sunshine." It is naturally inferred that the bricks made by the children of Israel in Egypt were sun-dried from the use of the straw in them. The making of bricks is often represented in the sculptures of Egypt. M. Maspero thus describes the process: "The ordinary Egyptian brick is a mere oblong block of mud mixed with chopped straw and a little sand, and dried in the sun. At a spot where they are about to build, one man is told off to break up the ground; others carry the clods and pile them in a heap, while others again mix them with water, knead the clay with their feet, and reduce it to a homogeneous paste. This paste, when sufficiently worked, is pressed by the head workman in moulds made of hard wood, while an assistant carries away the bricks as fast as they are shaped, and lays them out in rows at a little distance apart to dry in the sun."* As to the speed with which these bricks could be made, M. Maspero has to judge from the workmen of the present time, and he says that a modern good workmen can easily mould 1,000 in a day, and that after a week's practice he may be able to produce 1,200 or 1,500, and some can turn out as many as 1,800. As the modern appliances are the same as were used in former times, he assumes that the results would be similar. The dimensions generally

* *Adobes*, or *dobies*, is probably a variant of the Arabic *tob* or *toob*, allied again to the Coptic *tobi*, which was also the Egyptian word for brick.

* "Egyptian Archæology," p. 3.

adopted for ordinary bricks were 8·7 by 4·3 by 5·5—I presume these numbers represent inches —a larger size were 15·0 by 7·1 by 5·5.* He says, " Burnt bricks were not often used before the Roman period." In a note he adds that such bricks, " are found of Ramesside age at Nebesheh and Defenneh; even there they are rare, and these are the only cases I have yet seen in Egypt earlier than about the third century A.D." This note is valuable from its showing how exclusively sun-dried bricks must have been the rule in ancient Egypt.

Mr. Flinders Petrie has, in his explorations, come upon, in more than one instance, what might be called the "foundation stone" of Egyptian buildings, but as there was no stone, but a number of articles, such as gold, silver, lapislazuli, &c., a more exact term to give it would perhaps be that of "foundation deposit." Among the articles, and generally in a very central position, he always finds a small model of a mud brick.† This will show that along with the other objects it had most probably acquired some symbolic signification.

Maimonides gives a description of building mud walls; he says, " The builders take two boards, about six cubits long and two cubits high, and place them parallel to each other on their edges, as far apart as the thickness of the wall they wish to build; then they steady these boards with pieces of wood fastened with cords. The space between the boards is then filled up with earth, which is beaten down firmly with hammers or stampers; this is continued until the wall reaches the requisite height, and the boards are then withdrawn."‡ I understand that this is taken from the Talmudical authorities, but the great Rabbi does not explain in what part of the world it was practised.§

* In a note at the end of the volume the author says that, "in the Delta, at least, the sizes of bricks, from the Twenty-First Dynasty down to Arabic times, decrease regularly. Under the Twenty-First Dynasty, they are about 18 by 9 by 5 inches; early in the Twenty-Sixth, 16½ by 8¼ by 5; later, 15 by 7½; in early Ptolemaic times, 14 by 7; in Roman times, 12 by 6; in Byzantime times, 10 by 5; and Arab bricks are 8 by 4, and continue so to our times." Persian sun-dried bricks, at the present day, are generally about 8 by 2.

† See the *Illustrated London News* for Sep. 11, 1886, where drawings of these objects, with their relative sizes and position, are given.

‡ *Transactions* of the Soc. of Biblical Archæology, vol. viii. p. 409.

§ The Hebrew word for brick is *Lebanah.* This also means "white." The term is also applied to the moon, owing to its whiteness. Rawlinson, in his "Herodotus," suggests that there was some connection between the word "brick" and *Sin,* the Babylonian deification of the moon, who was the God of Architecture. This would be a very interesting point, if it could be established; but I understand that it is as yet doubtful.

Sanchoniathon, or whoever it may have been that wrote under that name, mentions Chrysor, and identifies him with Vulcan, as having invented many useful things; and it is quoted that,—" Men worshipped him after his death as a God, and they called him Diamichius —*i.e.*, the Great Inventor, and some say his brothers invented the making of walls and bricks. After these things, of his race were born two young men, one of whom was called Technites—*i.e.*, the Artist; the other, Autochthon—*i.e.*, Earth-born, or generated from the earth itself. These men found out how to mix stubble with clay, and to dry the bricks so made in the sun."

According to Professor Sayce the Assyrians had a month called Sivanu, which he translates the "month of making bricks." The Accadian name had the same signification; and it corresponded to the month of May. This would be the season after the rain, when the sun had begun to be hot, and the drying of the bricks would be easily accomplished.

These references will show, at least, how important this building material must have been looked upon in very early times. Its first use, or invention, was ascribed to mythical personages, thus attributing to it a kind of divine origin. In our own age it is difficult to realise how such ideas could have existed in the past, but from the authorities quoted there can scarcely, I think, be much doubt on the subject.

I shall now give a few details of the manner of building in mud, most of which are derived from what I saw in Persia. Many of the methods I saw there I have since found are also practised in other parts of the world.

It was pointed out to me that, in the larger towns, on entering a house, you have often to descend from the level of the street to the ground floor. It was explained that this results from utilising the earth on which the house stands, and thus saving the expense of transporting the building material from outside the town.

In good houses a foundation is laid, varying from two to four feet in depth, formed of rough stones or broken fire-burnt bricks, and piled up with mud and lime. This is carried up a foot or so above the ground, before the mud wall is commenced. In villages, where everything is rude, this foundation is made of any kind of rubbish that is found handy. This is a very interesting feature of mud architecture, to which I shall have something to say farther on. Its object is no doubt to give strength

where the wall would be liable to friction from the street traffic; and probably to prevent to a certain extent damp from rising. It would also be a safeguard against another serious danger —that is, if water were to accumulate by any chance round the base of the mud walls, and remain long enough to soak through, a very serious catastrophe might take place from the house tumbling down. I cannot recall to my memory any foundation of this kind in the mud houses of India. Village houses in the north-west of that country are usually built on a *chabootra*, which is a raised platform of mud, about a couple of feet in height, and this forms the floor of the house. This platform, by raising the foundation of the walls above the ground, may, perhaps, serve some of the purposes of the layer of stones in the Persian foundations.

The walls of Persian houses vary from two to four feet in thickness. This depends entirely on the quality of the house and the means of the builder. Thick walls make a cool house, and that is a desirable thing in the climate of Persia. If upper rooms are required, a greater strength of wall will be necessary. The mud is either laid on in layers or in the form of bricks.* As already explained, a layer of two or three feet of mud must be allowed to dry to a certain extent before another is laid on it, else the soft mud below will give way from the weight above. On this account both methods are generally practised. I remember an officer, who tried to make a mud hut for himself, when General Sir Samuel Browne's force was in Jellalabad. In this case, the walls were run up at once the full height required; this was not very high, for it was a small place, and he had dug a foot or two down below the surface for his floor, but his walls tumbled in. When he adopted the system of layers—letting each dry before the other was laid on—he succeeded, and made a very comfortable place for himself. In garden walls hollow bricks are used for the top, to give lightness. These bricks are called *sanduk*, a word meaning "box," which is descriptive of their character.† The tendency in mud building to produce thickness below in the walls, and lightness above, is most marked in the walls of villages and towns. These are all built with a visible batter. The earth taken out to form the ditch gives an abundant supply of material for a town wall, and a thick, solid mass at the base is necessary to give strength to the defence.

Where wood is plentiful, as in the province of Mazenderan, flat roofs are the rule. In large districts of Persia wood is scarce. I understand that south of Tehran there is very little timber, and there is also great danger from the white ants, so the vault- or barrel-roof is the usual means employed. According to Strabo, it was the same in Mesopotamia; he says, "All the houses are vaulted on account of the want of timber."* These vaulted roofs were frequent enough along the route I travelled. I have seen whole villages with them. Square buildings would have a dome; and a semi-dome at one end of a barrel-roof seemed to be a favourite method in that part of Persia. What struck me with surprise was the facility with which these villagers could construct such roofs. If there was any irregularity in the plan of the house, the barrel-roof was extended or drawn in, as the case might be, to cover the space. Of course in the villages it was all a very rough and ready kind of work, evidently done by no better principle than that of rule of thumb.

I was still more surprised when I learned that these vaulted roofs were constructed without centres. I can suggest so far how this is accomplished. Their bricks are said to be about eight inches square and only two inches thick; this gives a large flat surface and not a very heavy brick for its size. They place these bricks, not perpendicularly, but at an angle, so that the one rests partly on the other, and by the use of a little *gatch*, or gypsum, which is plentiful in Persia, they can be made to adhere till the key-brick is put in. Perrot and Chipiez give a drawing of an arched conduit at Khorsabad,† where the bricks are shown in the construction almost similar to what I have just described, and I feel sure that these conduits were also made without centres. In describing the construction of these conduits, the writer says: "We may believe the notion of building in this way would never have occurred to the Assyrian architects but for their habit of dispensing with timber centres."

* Sun-dried bricks are called *khest* in Persian; the fire-baked bricks are *ajur* or *aujur*. In Afghanistan, *khist* is used for both burnt and unburnt bricks. *Gill*, with a hard *g*, is Persian for mud.

† This recalls an old practice of Eastern architects, in constructing domes with pots, thus producing a considerable reduction of weight, and consequent diminution of thrust. A well-known example of this is the dome of St. Vitale, at Ravenna.

* *Strabo*, B. xvi. ci. 5. See also B. xvi. ciii. 10.

† See a *Hist. of Art in Chaldea and Assyria*, vol. I. p. 232, Fig. 93. See also Fig. 92, p. 229.

As the possibility of forming a vaulted roof without centering may be new to many in this western part of the world, I shall add further evidence, which is supplied by Perrot and Chipiez. They say: "We may refer those who are especially interested in constructive methods to M. Place's account of the curious fashion in which the workmen of Mossoul will build a pointed vault without the help of any of those wooden centerings in use in Europe. In our day, certainly, the masons of Mossoul use stone and mortar, but their example none the less proves that similar results may once have been obtained in different materials. A vault launched into mid-air without centering, and bearing the workmen who were building it on its unfinished flanks, was a phenomenon calculated to astonish an architect."* Rich gives details of a similar method, which is practised in Bagdad. It is also affirmed that the Byzantine architects produced arches, if not domes, without the aid of centres. M. Place* describes one method of making vaults without centres, which he saw in Kurdistan, and in this case they were women who performed the operation. They placed rings

TOMB, CONSTRUCTED OF MUD, WITH DOME.

* *Hist. of Art in Chaldea and Assyria*, by Perrot and Chipiez, vol. i p. 167.

* *Ninive et l'Assyrie*, vol. i. pp. 266-7. The church of Mousta, a town in the centre of the island of Malta, was built in the present century by the local masons; and they constructed the dome—said to be the third largest in Europe—without centres.

of dried clay, each smaller than the other, till the dome was completed. The evidence of these authorities, added to what I learned in Persia, would seem to establish that this was the practice over all the wide space from the Mediterranean to Central Asia.

In Persia the mud walls are covered over with a mixture called *kahgill*,* which is composed of mud and chopped straw; this serves to prevent the rains from washing away the walls, as it hardens the surface. The application of this mixture is generally repeated every two years.

Thus far, I have been dealing mainly with details of construction, and with ordinary dwellings. The general impression in most minds will no doubt be that mud building only belonged to a rude condition of civilisation, and produced houses that were little better than hovels. I have now to point out that this manner of building was developed into a highly decorative style which, in itself, would entitle it to a place in the history of architecture. This position, it appears to me, has been almost entirely overlooked by those who have written histories of architecture. Architectural writers always treat upon primitive wood constructions, because forms can be traced from it up to the highly developed styles of Greece, Egypt, and India. The same process can now be gone through with the primitive mud as a building material. Before I have done, I shall point out architectural forms which owe their origin to this source. At present my purpose is to show that it was carried to a pitch of finish and refinement that rendered it worthy for the palace or the temple. The following letter sent to me by General Sir Charles Wilson would, in itself, he a sufficient evidence. Sir Charles is well acquainted with western Asia, and being an engineer officer, he may be trusted as an authority. He says, "It may interest you to know that in Anatolia there is much mud building; and that most of the great buildings of the Seljuks, more especially their great palace at Konieh, were of mud faced with glazed tiles. Some of the minarets of their mosques, built with sun-dried bricks, arranged in patterns and faced with glazed tiles, or with the ends of the bricks glazed, are extremely beautiful in their decay. The Seljuk architecture is Persian with a development of its own." Here are mosques, or temples, and a palace constructed with sun-dried brick, which are declared by this high authority to be beautiful even in their decayed condition.

A somewhat similar development was reached in Peru, but with different materials. Squier, in his "Land of the Incas," describes the palace of Chimu, where the *adobes*, or sun-dried bricks were covered with stucco, on which beautiful arabesques were produced in relief.* From these ornaments he calls one of the great apartments the "Hall of Arabesques;"* of which he speaks in warm admiration, and adds—"no description can give an idea of the character of these *relievos*." In describing other ornamentation of the same kind, he says, "here, as elsewhere, there are traces of colour."†

I understand that the higher developed condition of this style of architecture in Persia was attained by covering the mud walls with glazed tiles. The tiles, it must be understood, were covered with ornament. Those who are familiar with the artistic qualities of Persian tiles may be able to form some idea of what could be thus produced. I regret to say that I saw very little of it. The part of Persia through which I passed had been so utterly devastated by the Turcoman raids, scarce a vestige of anything ancient remained. At Meshed, only, I saw a gateway, built with sun-dried bricks and covered with ornamental glazed tiles, but it was a very poor specimen of art; yet, it told me what might be done in this style if the work could be put into the hands of real artists. Meshed is celebrated, and is a well-known place of pilgrimage, from its having the tomb of the Imam Reza in it. The shrine is said to be decorated with some very fine tiles; but the whole enclosure, which is in the centre of the city, can only be entered by the faithful.

The interior of a mud building may also be decorated with glazed tiles; but in Persia *gatch*, or gypsum, is plentiful, and where ornament is required it is much used. In an old tomb, at Sarrakhs, I saw some particularly good ornament in this material; and it appeared to me to be all hand work. I chanced to come upon one room that impressed me with the capabilities of this manner of decoration. It was at a place called Mazinan, on the first march eastward within the Khorassan frontier. There appeared to be the remains of more than one town here; I strolled over to that which was nearest, and found that it was

* The word is *Kah* = straw, and *gill* = mud. In Indian villages the mud floors are washed over with a thin mixture of mud and cow dung.

* *Peru, or the Land of the Incas*, p. 135.

† *Ibid*, p. 154.; also at p. 411.

all formed of mud. It was rough work scrambling over the heaps, but at last I reached a mass that had probably been the *arg*, or citadel, and here is the description I jotted down at the time, immediately after the visit:—"It was with some difficulty that I was able to climb to the top, as the mound had been used as a quarry—a mud quarry—of the building material of the region. The mass forming the mound was artificial, for I found bits of red burnt bricks or vessels embedded in it. The top was a curious maze of rooms, courts, stairs, and roofs, much of it in a tumble-down condition, and it was rather difficult to find a way in places. From the superior finish of some of the rooms, I concluded that a governor, or some important man had lived in this place of security, but there were ruder additions, which showed that servants, or perhaps a more simple kind of people, had in all probability used some part of the place at a later time. The solid mass of mud or earth was about twenty feet high, and the houses were above that; still they were not all on the same level, for I went up and down short flights of steps. The whole was of mud or sun-dried bricks. Here I found at least one illustration of what can be done with such material which, from the high finish it presented, was rather a surprise to me. It was the best room in the place; the dimensions were small, somewhere about fifteen by ten feet. The lines of the interior were all perfectly straight, and at right angles to each other. The best houses in London are not more exact or more finished in their details than what I found here. The mud must have been carefully put on at first, but the high finish was produced by *gatch*, or gypsum. There were very handsome niches all round the walls, and the fireplace had been elaborate, but some act of destruction had taken place, and the fragments lay on the floor where they had fallen. The ornament was simple; there were some slight mouldings on the space between the niches. Lines had been drawn into the gypsum, and an ornament had been repeated by means of a stamp which had been pressed or imprinted when wet, producing a raised pattern; the impression left was so clean and perfect, it might have been gilt, and it would have been quite equal to the work we have at home on picture-frames. The contrast between this highly-finished interior with what was outside was very striking."

It was from what I thus chanced to see, even in this desolated region of Persia, that it began to dawn upon me what this peculiar manner of construction really had been. It was the exclusive building material of that part of the world. The simple houses of the villages are formed of it; the defensive walls of the towns, and which, owing to the Turkomans, were an absolute necessity to every village, were constructed of the same. The houses of the rich were also formed with it, and it had been developed into a highly decorative style of architecture; all this grew upon me, and I felt that this peculiar manner of building had not received the attention of writers its merits have entitled it to.*

One would not expect much durability from such walls, yet I was informed that there are walls of sun-dried brick in Ispahan which are over 300 or 400 years old. This quality of durability will no doubt depend upon the character of the soil. About Tehran the earth is sandy, while at Ispahan it is said to be more adhesive. In the northern part of Persia, according to Mr. A. Finn, of the Consular Service, the walls of the old city of Erig are still standing, and they are said to have existed for 1,200 years. There still remains at Cacha, in Peru, a wall of *adobes*, or sun-dried bricks—part of the temple of Viracocha, which was in a ruined condition about three centuries ago, when Garcilasco described it, and this wall is still standing to a height of 40 feet.† There are the remains of very old walls in Egypt. Maspero describes one at Abydos, called "Kom-es-Sultan," or "the Mound of the King," an old fortification, where part of the crude brick wall still stands, "from 24 to 36 feet high."‡ Maspero does not give a precise date, but from what he says, I understand that he places the origin of

* It has not been altogether overlooked. I learn that it has been dealt with in more than one work. M. J. F. Blondel's *Cours d'Architecture Civil*, Paris, 1777, his editor, Patte, gives a description of the mode of constructing buildings "toute on terre dite pisé." It is treated upon in a work, published in Berlin, written by H. F. Rödlich, entitled *Praktische und historische Darstellung Erdbankunst*. There is an article on "Pisé" in the *Dictionary of Architecture*, Arch. Publication Soc. Miss Yule, in Murray's *Handbook for Greece*, gives some very valuable references to it; and I would refer all who are interested in the subject to look up the *Quarterly Review*, vol. lviii. 1837, for an article "On Cob Walls," by Mr. Richard Ford, the father of Sir Francis Clare Ford, our Ambassador at Constantinople. It is a very learned article, and, at the same time, very amusing. I may also refer to a paper, read by myself to the Royal Institute of British Architects in 1887, on "Mud Architecture," and published in the *Transactions* of the Institute for that year.

† Squier's *Peru*, p. 407.

‡ *Egyptian Archæology*, by G. Maspero, p. 17.

this fortification as far back as the earliest of the dynasties. These examples are sufficient, although others might be cited, to show that mud walls need not be mere things of a day, and that they have in the past endured for centuries. There is a Devonshire saying regarding the "cob," or mud walls, of that locality, "A good hat and a good pair of shoes is all that cob wants." The pair of shoes here meant is a stone foundation such as I have described in the Persian houses; that is, to protect the lower part of the wall; and the hat is a sufficient amount of thatch, or covering, to the top of the wall to save it from the influence of rain. With such conditions, I believe that mud walls in Devon, even in our own damp climate, have stood for long periods of time.

I come now to one very interesting part of the subject connected with this peculiar style of building, and that is to point out a few architectural forms that can be traced back to it. The history of no architecture can be accepted as complete till every form in it has been followed through the past to its first origin. This has been fairly well done in Greek architecture, where the main features of it have been traced back to wooden forms. Many of the details of Egyptian and Indian architecture have also been shown to have had a similar derivation. In these details the wooden character has been so distinctly continued in the lithic reproductions, that the evidence may be considered as complete and reliable. In the material we are now dealing with, the forms are not so well defined, and the mutation from one material to another having taken place far back in their history, we have not the same trustworthy evidence to present regarding it. Yet, in some points it is fairly good, and in others we have every probability to support them.

The sloping jambs of doors and windows are peculiar to many old styles of architecture, such as the early Greek and Etruscan. Theories of origin for this have been often suggested, but we have no difficulty in accounting for them, if we suppose that the narrowness above was a form, and the natural result of the sloping walls of mud. The wooden parts of the first Greek temples were the portico and the wooden frame to support the roof; the walls of the cella were, in all probability, of crude brick. The late explorations at Olympia have led to an idea—but which still requires further support—that the cella of the Heræum at that place had been constructed of mud. This is the temple of which Pausanias states* that one of its original wooden columns still existed in his time, which is an evidence in itself of its great antiquity.

I have already explained how builders in mud—and which is well exemplified in Persia —construct their walls with a broad base, to give solidity below, and with a marked batter upwards to reduce the weight above. It has been suggested—and, I think, with every reason in its favour—that this explains the very marked slope of the perpendicular lines of the Egyptian pylons. All the authorities agree in stating that in the old temples the outer wall forming the temnos of temples of Egypt was made of crude brick, and as the pylon was the gate through this wall in front of the temple, the great probability of its being constructed of the same material is obvious.

At one time, the Romans were credited with having invented the arch. Later, it was supposed that they only derived it from the Etruscans. At the present day, no one would venture on locating the discovery of this constructive form with any one particular people or country. It is now known to be so old in Egypt, that its first beginning there cannot be determined. Vaulted and domed structures—such being principally used for granaries or storehouses—are also very ancient. The same may be said of Mesopotamia. Domed buildings are represented in a sculpture from Kouyundjik. M. Place's excavations at Nineveh show that the palaces there were roofed with vaults of crude brick, covered with stucco. Long ago, Mr. Fergusson reasoned out the probability of this from the plans of these buildings. The Chaldeans constructed vaults and domes two or three thousand years before our era; and M. de Sarzec's explorations at Tello has raised the supposition that the Proto-Chaldeans were capable of accomplishing the same kind of roofing for their houses.

When I had seen village after village in Persia with vaulted or domed roofs, and learned that such roofs could be formed without centres, the idea immediately suggested itself that these methods of building had existed from the most primitive times; and this supposition finds strong support, from the results of recent explorations in Egypt and Mesopotamia, which have just been referred to. While the necessity for wooden center-

* *Pausanias*, B. v. c. xvi.

ings for building vaults and domes was believed in, we never could have credited an early state of civilisation with this invention. Let this assumption regarding centres be removed, and the whole problem is changed. The earlier workers in mud or clay could not have been long in discovering how to spread their material over the space enclosed by four walls. They would, no doubt, have begun at first with small spaces, and a very little experience would soon have enabled them to deal with greater. If any one considers the matter, I think he must arrive at the conclusion that mud must have been first used for a long period of time before burnt-brick came into existence; and now that we know how easy it is to produce a roof with the mud, there is no great improbability in the assumption that the vault or dome, as well as the arch, all date back to a period when that material alone was in use. This also means that it was in a region where wood was scarce; for the existence of wood must have had in itself the tendency to prevent the invention of the vaulted roof. I do not suppose that the vault was invented in one region and was afterwards carried to another; my idea is, that wherever the conditions that I have described existed, such a mode of producing a roof would be arrived at. Whatever may have been the case, it occurred so far back in the history of our race that I fear the exact date is likely to remain as one we can only speculate upon. My own conclusions, which can pretend to nothing more than that of inferring what may have been probable, is at least based on our latest knowledge. Further explorations may give us more light and more certain data to reason upon.

Let me here direct attention to a very important development—in fact, to what might be called a complete change in architecture, which can be traced back to this origin of the arch, the vault, and the dome, which have been followed back to their first origin; the origin, I frankly admit, is theoretical, but it is a theory with much in its favour. Greek architecture was what is technically called "trabeate," that is, with columns supporting a lintel or architrave. This style originated from wood, and was, by means of the conquests of Greece and Rome, largely diffused over the old world. The change which occurred was that of the pier supplanting the column, of the arch doing duty for the lintel; the vaulted roof and dome at the same time taking the place of the straight lined roof and pediment. This important change in architecture, was, in fact, nothing less than the forms of mud origin supplanting those forms that had been derived from wood. The style to which this mutation is attributed is that known as the Sassanian, which belongs to the period when the dynasty of that name ruled in Mesopotamia. There are very few remains of this architecture left,* but in these few we find the arch, the vault, and the dome, combined into a full-grown architectural style. The rise of Byzantine architecture may have been independent, but it was nearly contemporaneous with the other, and was probably influenced by it. When the Mohammedans destroyed the Sassanian power, they seem to have adopted the architecture, for the arch and the dome became the principal features of the Saracenic style, which they carried westward to the shores of the Atlantic, and into Spain.

Not only did this style influence the architecture westward, but I am now in a position which enables me to trace it eastwards as well. Major Talbot, R.E., one of the officers on the Survey Department, with the Afghan Boundary Commission, chanced to visit a place called Haibak, which is on the main road from Kabul to Central Asia; it is to the eastward, and not very far distant from the site of the ancient city of Balkh. There are numerous caves in the locality, and as they are near to Bamian with its city of caverns, their Buddhist character may be assumed. Major Talbot luckily made very careful plans and sections of one group, known as the "Stables of Rustem." These he sent home to me, and on inspecting them I found that some of these caves had domes excavated in the rock, and that they were imitations of constructed domes. But more than this, I saw that the domes were the same in form as the few still remaining to represent what Sassanian architecture had been. One of the details which fully determines this, is the pendentive, by which the square form of the plan is converted into the round as the base of the dome. These are exactly the same in the Haibak caves as in the Sassanian domes. Major Talbot, by good luck, sent me a sketch of a pendentive in one of the Bamian caves, and it is similar to the others, showing that the Haibak examples were not exceptional. As these domes were exact copies of structural ones, they prove most distinctly that the Sassanian style was not limited to Mesopo-

* Among the few may be mentioned the Takht-i-Khosru at Cresiphon, and the palaces at Feruzabad and Sarvistan.

tamia, but must have extended eastward all through Persia and Khorassan to Central Asia. This discovery necessarily gives a new value to the Sassanian mode of construction, which has been known up to the present from about only half a dozen ruined monuments that have been left to us. A question is opened up by this new aspect of the case: that is, did this style first originate on the banks of the Euphrates or in Central Asia, both of them mud-building regions? This cannot be answered at present. The great probability is that it might have been contemporaneous along the whole region. Now that we know the Sassanian style existed so far east, it becomes evident that it was the architecture carried at a later date by the Mohammedans to Afghanistan and also into India, where it became the parent of the Mohammedan style in that country, and produced those beautiful musjids and tombs at Delhi and Agra, which command the admiration of all that are lucky enough to behold them.

I have described the foundations of a mud wall, such as they are in Persia, formed of burnt bricks or stones and lime; and also in Devonshire, where they are known as a "good pair of shoes," because they protect the feet, or lower part of the wall. In the remains of the temple of Viracocha in Peru the mud walls there have a stone base eight feet in height. With these examples before us, and understanding the necessary purposes they served, we may assume that such protective substructures were generally employed wherever this particular manner of building was in use. It is highly probable that in this rude constructive detail we have the first origin of that part of the architecture in the palaces of Assyria to which the great winged bulls in the British Museum belonged. It seems now to be accepted that these palaces were constructed of crude brick, or at least this material was the principal one employed; baked or perhaps glazed brick may have been used in the exterior of the walls, but the interior was of sun-dried brick, and covered with stucco. This latter part is exactly what I saw in Persia, and have already described in this paper. Along the base of these walls slabs of marble were placed, varying from three to about eight feet in height. These were generally sculptured, and the great bulls were represented on the portions of the slabs on each side of the doors. The development of this highly ornamental dado in the palace, from the base of the mud wall, is not a difficult problem to solve. The foundations I saw in the villages were formed of stones, half-bricks, or rubbish of any kind. In the better class of houses a more regular construction would be followed; and in palaces the covering of this with marble is what might be expected. I accompanied a visit of ceremony to the palace of one of the Shah's sons in Tehran, and I noticed that, in the room where we were received, slabs of alabaster, about three feet in height, went all round the base of the walls. These alabaster slabs in Persia are the counter-part of the marbles in the palaces of Assyria. In both cases they served the same purpose—they protected the lower part of the walls.

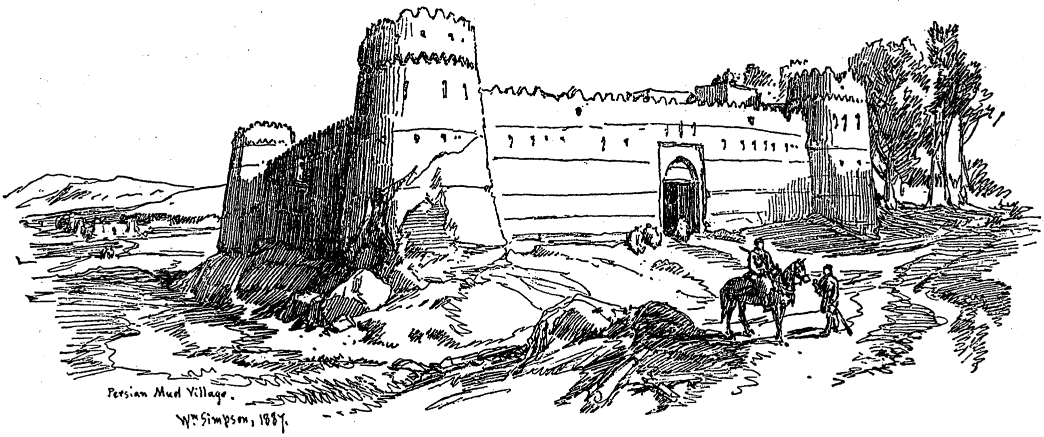
It is not so long ago, in this country, that the dado commanded a large amount of what, at the time, was known as æsthetic devotion. From the interest then produced, I feel justified in pointing out that here I have given the origin of at least one dado, and that a very important one, as the sculptures in the British Museum make evident.

I am inclined to suppose that the old masonry which we recognise under the word "cyclopean," which is known to all who have any familiarity with the archæology of Greece, had its first origin as the base of mud walls. No direct evidence exists on which to ground this supposition, and I only present it here as a mere guess. We do know that Greek towns were, at an early period, defended by mud walls. In B.C. 385, Agesipolis, King of the Spartans, managed to take the city of Mantinea, by damming up the river till its waters reached the base of the mud walls, which fell down as soon as their lower part was softened. Pausanias, writing of this siege, declares that such walls were, in one respect, better than stone:—"Though a wall of this kind," he says, "stands the shock of warlike engines, and is a better defence than a wall of stone [for stones are broken in pieces, and leap from their places, through the force of these engines], yet it is dissolved by water no less than wax, by the sun."* As an evidence that mud walls of cities in ancient Greece were not exceptional, Pausanius may again be quoted. He says that, regarding the method by which Mantinea fell, that "Agesipolis was not the inventor of this stratagem; but it was employed prior to him by Cimon, the son of Miltiades, when he besieged Eion, near the river Strymon."† These references show, not

* *Pausanias* b. viii. c. xviii. † *Ibid.*

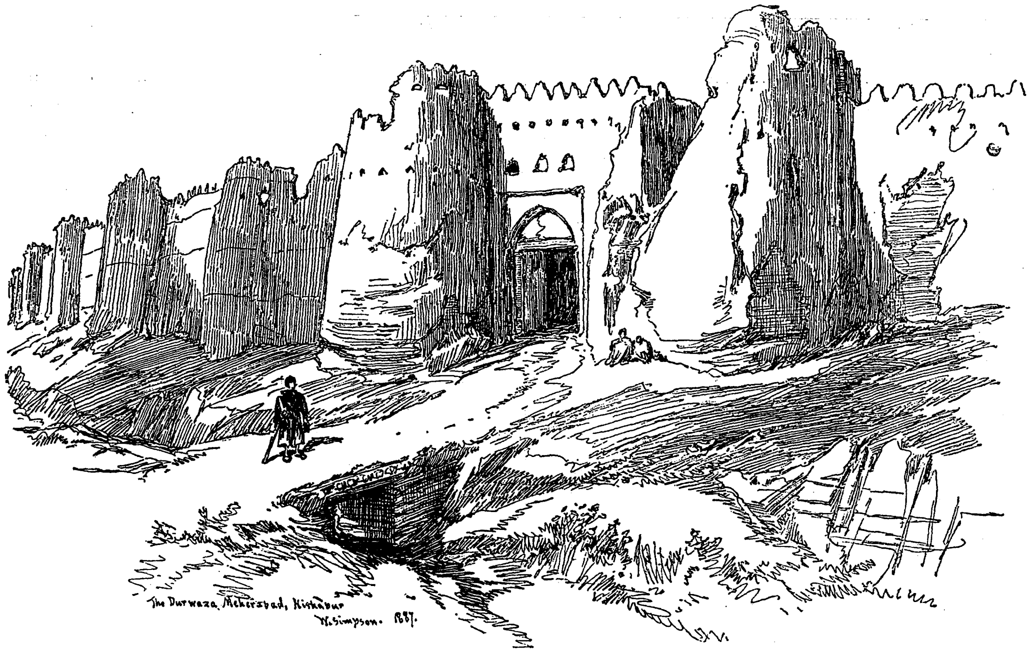
only that mud walls were common, but that, for security, a "good pair of shoes" was an absolute necessity in that early period, when Cyclopean masonry was practised. This suggestion first occurred to me from Squier's description of the Temple of Viracocha, where the old wall of *adobes* stands on a base of Cyclopean masonry 8 feet high and $5\frac{1}{2}$ feet thick. An illustration is given, which shows the exact character of the masonry.

FIG. 4.



PERSIAN MUD VILLAGE.

FIG. 5.



THE MUD WALLS OF NISHAPUR, KHORASSAN.

It was a source of some surprise to me to find that the Persian villages were, as a rule, exactly similar to those I had seen in the Khyber Pass and other parts of Afghanistan. They are square, formed with four high crenelated walls, and a round tower at each corner. The gateway is in the centre of one of the walls, and the mud houses are huddled together inside, one might say, "anyhow." Larger villages may have six or eight towers; small towns or large ones have more wall, and a larger number of towers. One of the first

things that drew my attention to mud as a building material in Persia was, when in passing a small town one morning on the march, I saw some men either building or repairing the walls and towers of the place. It then struck me that these defensive walls were, with only some trifling details of difference, almost identical with the walls we are so familiar with on the Assyrian sculptures. There is the same repetition of crenelated wall and tower, and constructed of the same material. I said to myself "these men, in the present day, are building an old Assyrian wall of fortification." Such defences must have begun at a very early date in Mesopotamia, long before the sculptures were produced from which we know what they were in appearance, and their construction has never ceased from that to our own time. This presents a very striking illustration of the continuity of type; and I confess that the discovery produced at the moment a very strong impression upon my own mind.

About one hundred miles east of Tehran there is a curious village called Lasgird* (Fig. 6). It is supposed to be very old, and its circular plan is said to have been first drawn on the ground by Las, the son of Noah. Not having heard of this personage before, I have been looking out for some reference to this member of Noah's family, but up to the present without success. The statement has already been made that the villages in Persia are square; such is the rule, and it will explain so far how a round one in their midst appears as something strange and remarkable. Imagine a huge rough cylinder of mud standing up, perhaps 30 feet or more in height, and covering a space about the size of that enclosed by the railings of Liecester-square. (These are only eye guesses as to dimensions). This great circular wall is so massive, that the houses of the people are constructed on the top of it, and form in a rather irregular manner two storeys. There are rude balconies, or I ought to say narrow ledges, on the outside which form communications. These are made of untrimmed branches of trees interlaced with twigs, on which mud is laid, but without a protective railing of any kind. Goats which I saw on these frail and dilapidated ledges were safe enough; but children, that I also noticed at play on them, seemed doomed sooner or later to certain destruction. The interior space formed by the circular wall is filled with store rooms and places where the cattle can be safely housed in case of an attack from the Turkomans. The only entrance into this strange structure is by a small opening about 4 feet by 3, which can be closed by a stone door turning on pivots. The smallness of this doorway was intended to prevent raiding enemies from entering during the chances of a rush, for it would be necessary to keep it open to the last moment to admit those of the villagers who were running home for protection. I noticed small stone doors in many places, and the purpose they served was that they could not be destroyed by fire;* the raiders had no time for regular siege operations. They made a rush upon a village, and caught all, man or beast, that were unlucky enough to fail in reaching the shelter of their mud walls.

I have dealt with this building material in the past; regarding its future I can say but little. In England here it was largely in use, so was wood, and that which is well expressed by the words "wattle and dab," which might be described as a combination of wood and mud. All these, as our material conditions have improved, have been slowly supplanted by the burnt brick or stone. "Cob" is still in use, to a limited extent only, in north Devon. It may be assumed that it is not suited for our damp climate. In dry climates, such as Persia and Egypt, it is likely to continue, for the simple reasons that it is a cheap material, and that a comfortable dwelling can be made from it. It might be utilised by some of our emigrants. Australia is reputed to be a dry country, and it might be employed by first settlers, particularly where wood is scarce. An emigrant, if he had a few hints and suggestions to start with, could easily construct a house for himself, and it would have one great advantage over a wooden house—it could not be burnt down. I have already mentioned in this paper how an officer at Jellalabad made a very comfortable hut for himself. What he did there an emigrant might easily do in Australia. The non-inflammable character of mud ought to be a strong recommendation to it in many parts of the

* *Gird* in this word is said to have the same signification as "girdle" in English—which may be rendered as "circle." [This block has been kindly lent by the Editor of the *Illustrated London News*.]

* The stone doors which are found so plentiful in the Hauran are formed after a wooden model, implying that wood had been the material at one time. The purpose of the stone doors in Persia makes it probable that a change at one period had taken place in the Hauran: unsettled times had come, and the doors had to be changed from wood to stone, to prevent burning, and thus give safety from sudden attacks.

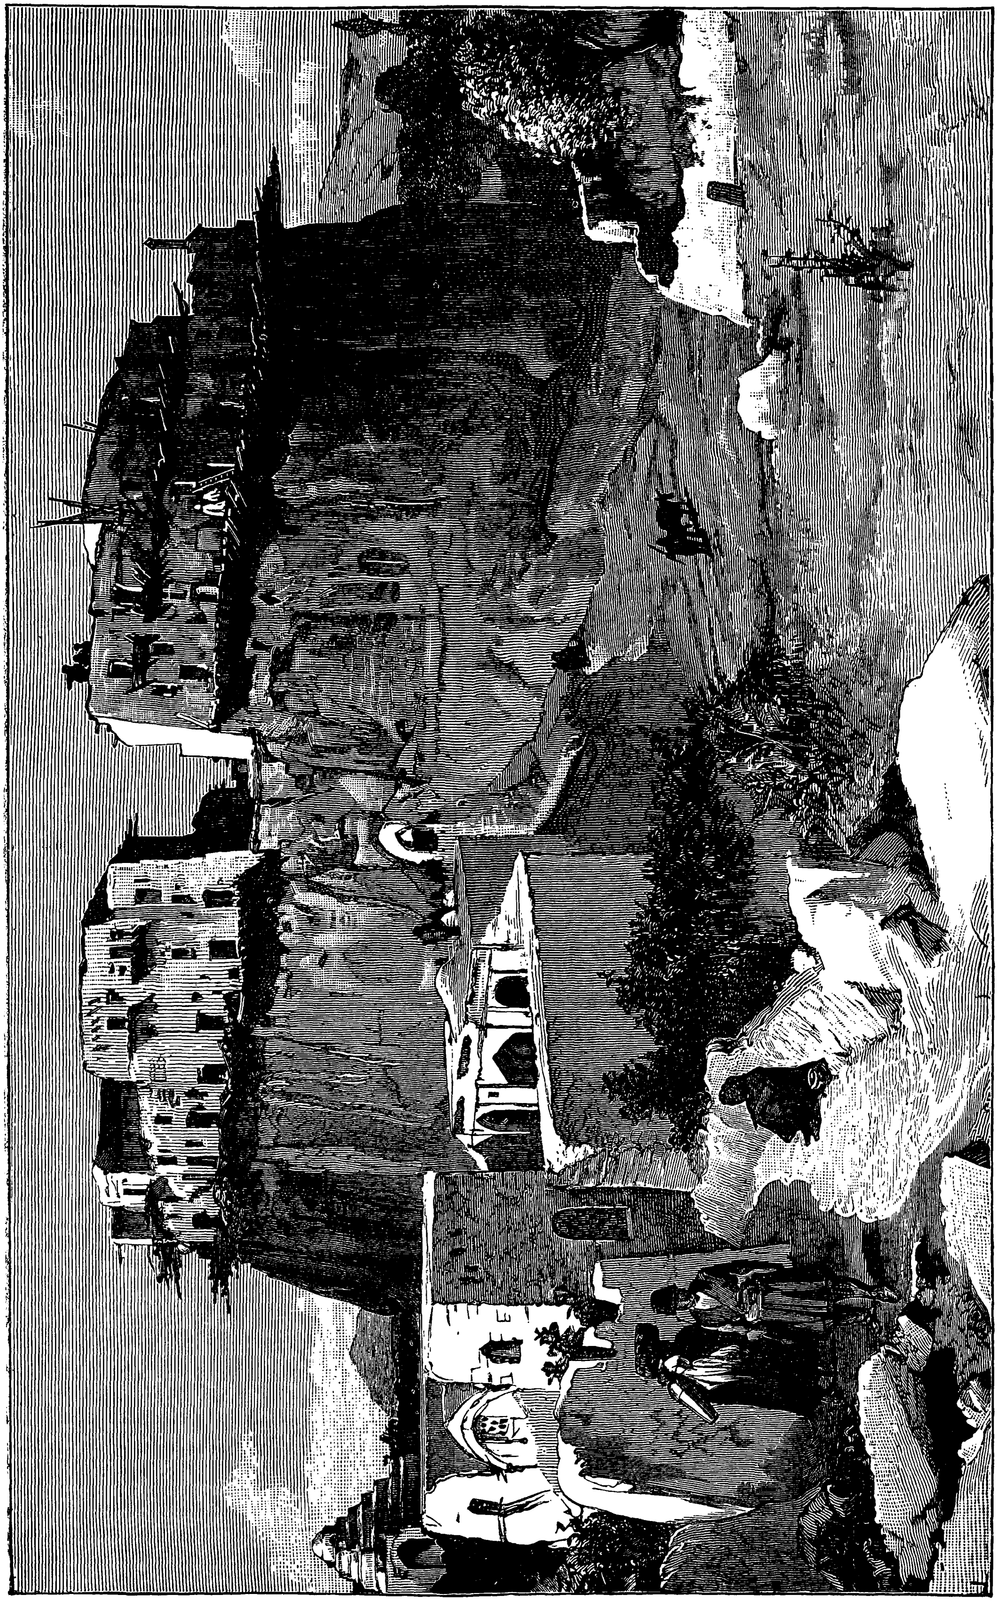


Fig. 6.—Lasgird.

country. I might mention a country like California as one where this material might be valuable. California has a dry climate. When I was in San Francisco, in 1873, that town was almost wholly constructed of wood. Stone was feared owing to the chances of earthquakes. While there, I visited the Church of St. Francis, built of *adobes* a century before, and it had stood firm and secure all that time. It occurs to me—but I

FIG. 7.

STONE DOOR, LASGIRD.

have no right to speak as an expert—that a house built of thick mud walls and wooden joists and rafters, would be tolerably safe during an earthquake, unless it was a very severe shock; such a house would also be safer than a wooden one from fire, which has always been a great danger in San Francisco. I have only referred to California as an example; what has been said of it will apply to many other parts of the world, where it is possible this building material might be used with advantage even in our own day.

DISCUSSION.

Mr. H. STANNUS said when the subject appeared on the paper, many might not exactly see the connection between mud architecture and applied art, but, after listening to the paper, they would be of opinion that mud, as used in the dwelling of man, was applied art. All arts had arisen from the three necessities of man, viz., food, clothing, and shelter; and mud architecture had been exceedingly useful to the shelter of man, protecting him from heat of the sun, from cold, and from fire, though, he was afraid, not from damp. During the reading of the early part of the paper he had been reminded of the early Assyrian times; and bearing in mind how Assyria, in the upper part, and Babylonia, in the lower part, of Mesopotamia, were both watered by the two rivers, and by their innumerable affluents, which flowed down from the mountain of Armenia, it would be easily understood that mud must be the material used for building. Builders who had not convenience for transportation must use the local material. Obviously Mesopotamia, being an alluvial plain, consisting of the mud brought down by the rivers, would supply this. The books on Assyrian art show how the commencement of the king's palace, or the village which contained the group of palaces, was the heaping-up of a platform from 20 to 40 feet above the plain. This platform had great value for several reasons; in the first place it protected the people from flood; in the next place it protected them from the mists which settled down in alluvial valleys; and it was moreover a protection against enemies. Very early in the history of the human race the tower of Babel was built for some of these reasons. The people of that country were great star-gazers, and obviously any platform which lifted them above the mists into the clearer atmosphere, would be of great advantage. We had been much interested in the statement as to the origin of the door-jambs. Mr. Simpson had not quoted, though he must have known, the instances of buildings with architectural pretensions in Persia in which columns and door-jambs still remained, but without any wall remaining between the jamb and the column; the probability being that the door-jambs were placed there to get the true sharp angle, the intervening space being filled with mud. A wall has two duties to perform: to support and to enclose. The portion which was a door-jamb, or buttress, or pilaster, supported the beam; and that portion which was the plain wall, served the part of a curtain, and merely enclosed. It was therefore exceedingly likely that the door-jambs were first built, and then the curtain of mud was placed between to serve the enclosing function of the wall. With regard to the statement that it was necessary for mud to have a "good pair of shoes," it seemed to him that the same thought must have occurred to the Assyrians who used slabs to protect the walls. There was no doubt that the "dado" had its origin in the earlier Assyrian prototypes. As to the suggestion that mud might be utilised for building purposes in Australia, he might observe that it was a necessity that the soil should be clayey, otherwise it would not hold together. If the soil were sandy, he supposed the reader of the paper would qualify the suggestion to that extent.

Mr. T. CHRISTY said that, having lived in China for some time, he had been much struck with the fact that in the construction of large Chinese houses a tier of stonework was invariably used. In many of the large temples they would not even go to the trouble of building entirely with mud, but they got a curved tile made from mud, burnt or baked—if they could afford straw they burnt them a little more—and the space between the tiles was filled with mud. This mud was obtained from the sluggish rivers, and consisted of a sort of ooze from the banks, which was plastered into the walls, as they found the vegetable matter was so much more advantageous than the ordinary clay which was found in the fields. Slabs were placed in front of the houses, like a dado, to protect the walls from injury. The Chinese always took care that the houses faced in the "proper direction," and the eaves were used for storing dried poultry under for winter consumption. No doubt Mr. Simpson would remember that when he visited Siam he found very much the same system of architecture had been employed in the construction of the temples. He thought the paper had cleared up an important missing link in connection with architecture.

Mr. MARTIN WOOD did not know whether he ought to find fault with the title of the paper, seeing that the first part of it related more to bricks than to mud. He should be glad to know whether Mr. Simpson was clear upon the point that the use of mud in Mesopotamia was due to the want of timber; for he had always been accustomed to suppose that those regions, now so arid and bare, were at one time tolerably well wooded. He should also be glad to know whether Mr. Simpson could give any explanation as to the difference between a fire-burnt brick and a sun-burnt brick, and the degree of protection they afforded from the sun. He knew that when the palatial barracks at Allahabad were found uninhabitable because of the heat, a Commission was appointed to inquire into this subject; and Lord Napier, who was upon the Commission, insisted on some of the arches being filled up with sun-dried bricks. The paper had developed a more practical side than he anticipated, for it not only dealt with the past, but also the future. He thought if a large part of the soil of Australia were sandy, the suggestion thrown out in the paper could not be adopted. But his own impression was that there was a large amount of alluvial soil in Australia. The suggestion as to countries where earthquakes were prevalent was, to his mind, an exceedingly good

one. As to mud supplanting wooden-built houses in California, he thought this point was one which ought to be strongly urged by way of checking the destruction of timber on the Pacific slope.

Mr. SCOTT MORTON said, like his friend Mr. Stannus, he was a member of a guild in which applied art was a very important subject, and he did not see how a paper on mud could assist them much on matters appertaining to building. Such methods of building in this country must be of very limited application, owing to the small amount of sunshine. In Eastern climes the sun was a very important factor in hardening the mud. One great drawback to the use of mud in this country was frost, for mud, if exposed for a short time to frost, became useless for walls. He thought it would be extremely interesting to shut Mr. Simpson in a room and get him to use his wonderfully facile pencil and colour brush, so as to give them an insight into what he had seen during his travels, in those combinations of mud and tiles to which he referred. If he was in possession of any drawings, he hoped that on a future occasion he would give those interested in this subject an opportunity of looking at them. No doubt Mr. Simpson could show them the application of stamping the mud, which subject was a very wide one, the range being practically unlimited. The subject of foundations, too, which had been referred to, was certainly a very interesting one. While speaking of Mesopotamia, a Scriptural reference passed through his mind, which was to be found in the book of Ezekiel, of people who built temporary mud dwellings, and a reference to floods coming and hailstorms. When they considered that many of those great plains in the rainy season were flooded, they could understand the value of foundations for erecting mud buildings upon. In Africa the natives raised their dwellings on posts, in order to avoid danger from the flooding, as well as to get free of vermin. A great deal had been said as to the construction of arches and domes without centering, and about the skill of the people in constructing these, and this certainly opened up a very interesting subject of inquiry. In constructing a dome, the first course was laid simultaneously; and started on the principle of an arch upwards and inwards. This course would support itself, and if a little notch were made in the next course, it would rest on the first, and so the dome could be constructed without centering.

Mr. H. LONGDEN said it was very charming to hear that mud buildings were decorated with a product of mud, viz., tiles which were merely burnt earth. This seemed a special example of the fitness in things. To his mind, Persian tiles were the most beautiful that were ever made. If anyone wished to get the finest colouring in tiles, they must look to Persia as the origin of their colouring, and most probably for design also. He thought the paper a most interesting one, as it had opened up many side views which he had not expected.

Miss WEBSTER said it might interest the meeting to hear that within her recollection two cottages had been built by settlers, on the borders of the New Forest, entirely of mud. Reading Abbey was also built of a greyish kind of earth intermixed with small pebbles.

The CHAIRMAN thought the use of mud, as a building material, was properly connected with the Applied Art Section. Having had considerable experience in mud buildings, and seen mud building by others, he knew the great importance of the material under certain circumstances, and he thought Mr. Simpson had rightly drawn attention to this, that primitive building differs in different places, according to the material available. Mud, as we understand it, is readily applicable to the little round cell, cottage, hut, or whatever we may call it. Built in a beehive shape, it was similar in point of construction to the houses built by the Esquimaux with snow. So in primitive countries, where timber was very scarce, or not to be had at all, mud was a natural and convenient kind of material to use. Mr. Simpson had noticed the construction of mud domes without centering. A dome, being built in horizontal courses, does not need the support that an arch requires. Writers on dome construction generally noticed that it does not need centering. The expression, quoted by Mr. Simpson, from Messrs. Perrot and Chipiez, describing a vault "launched into mid air," is a little inaccurate. The kind of earthen wall mentioned by Mr. Simpson, and commonly called *pisé*, made by ramming powdered clay between boarded sides, differs from mud work, in being made of dry earth. The sloping jambs of doors and windows gave a great appearance of strength to the building. Mr. Simpson was no doubt familiar with this construction, both in Egypt, and in old buildings of the Patan period at Delhi. A quotation was made in the paper from an ancient writer as to the superiority of mud over masonry in defensive fortresses, and the same advantage is gained by the use of earthwork in modern fortification, in which stone walls are not exposed but concealed by earthworks. In India, mud forts had been well known for many generations, and are very strong. The villagers in North India, when building a wall, did not always make the mud into bricks, but used large lumps, and laid them one on top of the other.

The vote of thanks having been put by the Chairman, was carried unanimously.

Mr. SIMPSON said, with regard to the remarks of Mr. Stannus, he might say, there was stone in Mesopotamia, but wood had to come from a very long distance. Strabo is the authority for the scarcity of wood in that country, which, no doubt, obliged the natives to build barrelled roofs, as

he had already stated. Mr. Christy's remarks as to the mode in which the Chinese built their houses was interesting to him, because, when he was in China, he did not chance to see any mud buildings, and, on that account, he could add nothing to what Mr. Christy had said about the Chinese. He regretted to say that he was unable to answer the question put by Mr. Martin Wood, as to the difference between the two kinds of bricks as a protection against the sun. Sun-dried bricks were not generally stamped, and the only place he had seen stamped bricks was in Bengal; but there were, of course, fire-burnt bricks.

Miscellaneous.

THE WOOL INDUSTRY OF THE PUNJAB.

The United States Consul-General at Calcutta, in a recent report to his Government, states that the Punjab, with its 6,551,180 sheep and its 83,000 maunds of wool, annually made into shawls, carpets, blankets, &c., holds an important place in the sheep and wool industry. Shearing in the Punjab is done twice a year generally, though, in a few of the districts, there is an intermediate shearing in June. The wages paid consist of one-twentieth of the wool shorn. A man can shear twenty unwashed and twenty-five washed sheep in a day. Wool sorting in the Punjab is done in a very primitive style, and in some parts it is not done at all. Washing of the wool is not common, nor is it very necessary, except in the case of wool loaded with sticky matter. Unless done carefully, and with suitable soap, it is very bad for the wool, and picking by hand or some other process is, in every case, still necessary for the removal of burrs, thorns, seeds, &c., which are entangled in the fibres. The picking out by hand of foreign bodies is done everywhere. It is a very tedious process in the case of wool grown in places abounding in thorny bushes and undergrowth, and the workers are nearly always women. The mere process of hand-picking involves a certain amount of teasing out of matted portions of wool; but where scutching and combing are uncommon—a state of affairs which appears to exist in the Jung district, and in Jullinder and Ludhiana—something more than this is necessary. The wool must be reduced by hand to a mass of fluff; but to effect this, in most districts, either the *pinjan* (bowstring) or the comb is used. A bow is suspended, string downwards, at such a height that the string passes through the wool to be operated upon. The string is then made to vibrate violently, either by twitching it or by striking it with a hammer, and the vibrating string catches up and scatters the wool about. The instrument is used in nearly every district of the Punjab, and nearly everywhere the work is done by men of some low caste. In most places there is a separate caste of *pinjas*. The bowstring and the comb are not merely alternate instruments for effecting the same purpose: the former opens out the wool and loosens its mass, bnt leaves the fibres lying confusedly in all directions; the latter tends to open the wool, and also to lay the fibres side by side in parallel lines. The former is used when woollen thread is wanted, the latter when the spinning of worsted is the object. The combs used in the Punjab are of two sorts, single and double. The double are reported to be used only in Gujurn-walla, Amritsir, and Lahore, and the single comb is found in Sialkot and the Ferozepoor. The double comb (*shana kanga*), which is the more effective of the two, consists of a piece of wood laid on the ground, with two parallel rows of vertical iron teeth standing on it, there being twenty teeth, about four inches high, and the intervals between the two rows and between the teeth being one inch and one-half an inch respectively. The teeth are rigidly fixed to the platform, which is kept steady by the operator's feet. He does the combing by taking a flock of wool, striking it upon the teeth, and drawing it gently downwards through the teeth at right angles to the rows. The single comb is a very primitive instrument, and has very imperfect effects. In its rudest form, it is a mere *panja*, or claw, which cleans rather than combs. Neither the single nor the double instrument is used for combing short stapled wool, nor could it be employed with any effect for such a purpose. The wool, when teased, or scratched, or combed, as the case may be, is made up into balls (*punis*). The next operation is spinning. The *charkhi* is formed of two parallel discs, the circumferences of which are connected by threads, and over the drum so formed passes a driving band, also made of thread, which communicates a rapid motion to the axis of the spindle. The end of a *puni* is presented to the point of the spindle, which seizes the fibre and spins a thread, the *puni* being drawn away, as the thread forms, as far as the spinner's arm will reach. The thread is then slackened, and allowed to coil itself on the body of the spindle until the latter is full, when it is removed. In some parts, notably in Cooloo, the *charkhi* is quite unknown, and the instrument used is the *dherna*, or *takli*, a pointed instrument, similar to the unattached spindle of an old-fashioned spinning wheel, with a disc at the blunt end. A portion of a *puni* is drawn out and held to the upper part of the instrument, and wound round it. The *dherna* is then spun round in the hand, and when it has got firm hold of the wool, it is allowed to hang in the air suspended by the thread it is spinning, the right hand of the operator keeping up the rotary motion, while the left hand regulates the draft of the wool. When the thread is getting so long as to put the *dherna* out of reach or to let it touch the ground, the draft of wool from the *puni* is stopped, and the piece that has been spun is wound

on the *dherna*. The *charkhi* is said to produce a more even and reliable thread than the *dherna*, owing to the greater regularity of the rotatory motion in the former machine. In the hills spinning is done by all classes of both sexes and all ages, from ten years and upwards. Consul Merrill says that, in Cooloo, every tenth person met on the road is spinning wool with a *takli*, as he or she walks along, and it is no doubt the portability of the instrument, as much as anything else, that causes it to be used instead of the *charkhi*. When yarn has been spun, it is generally found that it is too thin, in places, to bear the strain of weaving, or when a coarse thick fabric is required. The yarn has, therefore, to be doubled or trebled, and sometimes more than three folds are given. For twisting, as this process is called, the *charkhi* can be used, and also a form (called *masan*) of the *dherna* or *takli*, the difference being that the upper end of the spindle has a narrow, curved groove, about half an inch long, running from the point along and round the rod, and in this groove the threads, twisted together, are run. Yarn, single or double, is sold in the hills, in balls or on reels of various shapes; but, before weaving, it must be wound on reels, and the warp prepared. Two reels are fixed at the end of sticks on a pivot, on which they can revolve. A double row of sticks or reels is then planted on the ground, at intervals of about two yards, extending either in a straight line or in a loop to the length which the piece of cloth is to have. The warp-layer then takes a stick and reels in each hand, and walks along the line, dropping the threads, one inside and the other outside the sticks alternately, so that the two cross each other between each pair. Having got to the end of the line, the operator returns in the same way, and so on, up and down, until enough threads have been laid to make the required width of the fabric. If the cloth is to have a longitudinal stripe or a check, reels of different colours are used, and the proper number of threads laid on with each colour. Some of the wool used in the Punjab is brought from Beloochistan, where the pasturage is peculiar, and from Cashmere, where the water is said to contain valuable qualities. Thousands of the inhabitants of Cashmere, in the last 50 years, have come over from their native valley to settle in the Punjab, and, encouraged and assisted by European agents, have engaged in the manufacture of shawls.

MEXICAN SILK INDUSTRY.

The *Moniteur des Soies* says that Mexico is well adapted to the culture of the mulberry and to the rearing of the silkworm, owing to its excellent climatic conditions. In this country every variety of climate is found—in certain regions a mild and equable temperature all the year round, and in others severe cold. The idea of cultivating the silkworm first originated in the minds of some Spanish monks, who had visited the extreme East and found, on returning to Mexico, that it was as suitable for this industry as China itself, and they planted mulberry trees in considerable numbers. After a time these plantations were neglected, until M. Chambon, a Frenchman from the Ardèche, assisted by the Mexican Government, took them in hand. He also distributed silkworms eggs of the best quality, and taught the Indians the best methods of rearing the worms. Mulberry plants were then brought from France, chiefly from the departments of the Ardèche, Vaucluse, and Isère, and five millions of these young trees were planted in the States of Puebla, Mexico, Guanajuato, and Jalisco. The greatest advantage that the Mexican silk grower has over his Chinese and European rivals is due to the complete renewal of his mulberry plantations; for, in this country, the trees are young, well selected, and spaced out in lands costing only a nominal sum. In addition, the Mexican grower, having everything to learn, only devotes himself to the modern scientific aspect of the question, and is not hampered by tradition or routine. Practical schools of sericulture under the direction of M. Chambon have been established in several States, many having already been opened at Guadalaxara, and throughout the State of Jalisco, at Léon, Morelia, Puebla, and Toluca, and in the environs of Mexico at Mixcoac, Texcoco, &c. Others are shortly to be opened in the north, and in the south at Oaxaca and Monterey. It has been found that the yield from an ounce of seed is from forty-five to fifty kilogrammes of cocoons (kilogramme=2·2 lbs. avoirdupois), that is from ten to fifteen kilogrammes more than the average French yield. This average, it is stated, can be increased, and in that ease it would exceed the yield in the best districts of Italy and Austria. The President of the Mexican Republic, General Porfirio Diaz, obtained from a trial on his estate at Oaxaca, 200 kilogrammes of cocoons with three ounces of seed, or a yield of sixty-seven kilogrammes to the ounce. The Governor of Jalisco has given every assistance to the development of the silk industry in that State, and in view of the fact that the Mexican women exercise considerable care and patience in tending the silkworms, that the mulberry trees grow in this country three times as quickly as they do in Europe, and that the weaving of silk can be effected at home at a trifling cost, there is every reason to believe that in a few years Mexico will hold a good place among silk-exporting countries. The proximity of the United States is an inducement to Mexico to become a silk-producing country, as unbleached silk is admitted free into the United States, while European tissues are practically excluded. The rapidity with which the industry of silk weaving in the United States is developing, coincident with the almost complete failure of sericulture, opens a vast field to the Mexican grower. For some time past small factories for reeling and twisting silk hair existed in Mexico, and in the city of Mexico a factory has been established to which dye

works have been added. In this factory there are six Jacquard looms for the manufacture of silk *rebozos* (wide silken scarves much worn by the Mexicans). Other factories for the manufacture of *rebozos* have been established in the country, particularly at Purbla and San Luis Potosi. The amount of silk annually worked up may be estimated at £30,000. The organsine is used for the manufacture of *rebozos*, and the weft silk, at Mexico and Monterey, for making up passementerie and hats, and for upholstering purposes. The manufacture of galloons is assuming considerable importance in Mexico, and scarcely any of these articles are now imported.

TABLET, OR COMPRESSED TEA.

Brick tea has usually but little to commend it, as it is known to be composed of the sweepings and dust of the Chinese tea factories. Its chief market is Russia, which took from China last year 2,005,548 lbs., one half the usual export, due, it is said, to the scarcity of tea dust. A new article in tea has, however, recently sprung up in China, in the form of tablet tea, which appeared in the trade returns of Kiukiang for the first time last year, machinery having been erected there for its manufacture, and the quantity shipped from that port was 493,392 lbs. Tablet tea is made from the very best quality of tea dust. It is formed, by pressure alone, into small cakes, which are perfectly hard and solid, and somewhat resemble chocolate in appearance. The material is not, like brick tea, moistened with steam, before being compressed, and the flavour is not in any way impaired by the process of manufacture. As it takes up little space, and is most unlikely to get spoilt or damaged, it is recommended as a convenient form of tea for travellers, backwoodsmen, or armies in the field. With these conveniences, and a guaranteed good quality, there is no reason why tablet, or compressed tea, should not become generally used.

Obituary.

PETER WILLIAM WILLANS.—On Monday, 23rd May, Mr. Willans, the well-known engineer, was thrown from his dog-cart, when his skull was fractured, and from this accident he died shortly afterwards. The following particulars of his life are obtained from *Engineering* :—Peter William Willans was born in November, 1851, at Leeds, Yorkshire, and was educated at the public grammar school of that town. He served his apprenticeship with the firm of Carrett and Marshall, afterwards known as Hathorn, Campbell, and Davey, and in August, 1872, he entered the employment of Messrs. John Penn and Sons, of Greenwich, where, after working for a few years in the drawing office, he first brought out his patent three-cylinder engine. On leaving Messrs. Penn's he for some time acted as consulting engineer with Mr. A. Ward, as Willans and Ward, but he soon afterwards became associated with Messrs. Hunter and English, of Bow, who took up the manufacture of the Willans engine for marine purposes; eventually, however, as he was then living near Kingston-on-Thames, he, about thirteen years ago, started works on his own account in partnership with Mr. Mark H. Robinson, at Thames Ditton. Here he brought out the two-cylinder central valve engine, which is so much used for electric lighting, and which has made his name so deservedly famous in every part of the country. Mr. Willans's family had for several generations taken a leading part in the cloth trade in Leeds, and as his father owned some large mills, it was always intended that the son, the subject of this notice, should be brought up in the woollen business; but through the persuasion of Mr. W. H. Massey, an old schoolfellow, he became an engineer. Mr. Willans was elected a member of the Society of Arts in 1888, and so lately as May 4 he joined in the discussion on Mr. Shoolbred's paper on "The Bradford Corporation Electricity Supply."

MEETINGS FOR THE ENSUING WEEK.

TUESDAY, JUNE 7 ... Royal Institution, Albemarle-street, 3 p.m. Prof. R. C. Jebb, "Some Aspects of Greek Poetry." (Lecture III.)
Photographic, 5A, Pall-mall East, S.W., 8 p.m.

WEDNESDAY, JUNE 8 ... Geological, Burlington-house, W., 8 p.m. 1. Mr. R. J. Lechmere Guppy, "The Tertiary Microzoic Formations of Trinidad (West Indies)." 2. Rev. A. Irving, "The Bagshot Beds of Bagshot Heath (a Rejoinder)." 3. Johnson Pasha and Mr. H. D. Drummond, "Notes on the Geology of the Nile Valley."
Royal Literary Fund, 7, Adelphi-terrace, W.C., 3 p.m.
United Service Institute, Whitehall-yard, S.W., 3 p.m. Capt. W. H. James, "Magazine Rifles: their latest Development and Effects."

THURSDAY, JUNE 9...Royal Institution, Albemarle-street, W., 3 p.m. Mr. R. G. Moulton, "Faust." (Lecture III.)
Mathematical, 22, Albemarle-street, W., 8 p.m.

FRIDAY, JUNE 10...United Service Institution, Whitehall-yard, S.W., 3 p.m. Mr. J. Furley, "Ambulance Work and Material in Peace and War."
Royal Institution, Albemarle-street, W., 8 p.m. Weekly Meeting, 9 p.m. Prof. Dewar, "Magnetic Properties of Liquid Oxygen."
Astronomical, Burlington-house, W., 8 p.m.
Institute of Brewing, Chemical Society Rooms, Burlington-house, Piccadilly, W., 8 p.m. Dr. Walter J. Sykes, "Mashing and Fermenting from a Distiller's point of view."
Physical, Science Schools, South Kensington, S.W., 5 p.m. 1. Dr. J. H. Gladstone and Mr. Hibbert, "Some points connected with the Electro-motive Zone of Secondary Batteries." 2. Prof. W. E. Ayrton and Mr. Mather, "Workshop Ballistic and other Shielded Galvanometers."

SATURDAY, JUNE 11...Botanic, Inner Circle, Regent's-park, N.W., 3¾ p.m.
Royal Institution, Albemarle-street, W., 8 p.m. Prof. H. Marshall Ward, "Some Modern Discoveries in Agricultural and Forest Botany."

Journal of the Society of Arts.

No. 2,064. Vol. XL.

FRIDAY, JUNE 10, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

CONVERSAZIONE.

The Society's *conversazione* is fixed to take place at the South Kensington Museum (by permission of the Lords of the Committee of Council on Education) on Wednesday evening, June 29th, at 9 p.m.

Each member will receive a card for himself, which will not be transferable, and a card for a lady. No tickets will be sold.

The cards will be issued shortly, and further particulars as to arrangements will be announced in future numbers of the *Journal.*

Chicago Exhibition, 1893.

TRANSPORTATION COMMITTEE.

A meeting of the Transportation Committee was held on Thursday, 2nd inst. Present:—Sir Douglas Galton, K.C.B., D.C.L., F.R.S. (Chairman), Sir Nathaniel Barnaby, K.C.B., Henry Chapman, James Dredge, Francis Elgar, LL.D., Walter H. Harris, George Norgate Hooper, with Sir Henry Trueman Wood, M.A., Secretary to the Royal Commission.

ELECTRICAL COMMITTEE.

A meeting of the Committee for Electricity was held on Friday, June 3rd. Present:—William Henry Preece, F.R.S. (Chairman), Sir Frederick Abel, K.C.B., D.C.L., D.Sc., F.R.S., Prof. W. Grylls Adams, M.A., D.Sc., F.R.S., R. E. B. Crompton, Henry Graham Harris, David Edward Hughes, F.R.S., Gisbert Kapp, W. M. Mordey, Hon. Charles A. Parsons, John Perry, D.Sc., F.R.S., C. E. Spagnoletti, Prof. Silvanus P. Thompson, D.Sc., F.R.S., with Sir Henry Trueman Wood, M.A., Secretary to the Royal Commission.

FINE ARTS COMMITTEE.

A meeting of the Committee for Fine Arts, was held on Tuesday, 7th inst. Present:—Sir Frederick Leighton, Bart., P.R.A. (Chairman); Wyke Bayliss, Pres.R.S. Brit. Artists, Philip H. Calderon, R.A., Sir James D. Linton, P.R.I., H. Stacy Marks, R.A., Deputy-President R.S.P.W.C., Walter W. Ouless, R.A., Marcus Stone, R.A., W. Hamo Thornycroft, R.A., Sir Henry Trueman Wood, M.A., Secretary to the Royal Commission, and J. W. Beck, Secretary to the Committee.

Proceedings of the Society.

INDIAN SECTION.

Thursday, May 19, 1892; Sir Charles Bernard, K.C.S.I., in chair.

The Chairman apologised for the absence of Mr. Baines, who had not yet arrived in England.

The paper read was—

THE ADMINISTRATION OF THE IMPERIAL CENSUS OF 1891 IN INDIA.

By Jervoise Athelstane Baines, I.C.S.,
Chief Census Commissioner for India.

Whilst preparing this paper, in India, one of the main difficulties that met me at the outset, not to count the proverbial first step, was, what was the extent of acquaintance with census operations in general, and of those in India in particular—and, indeed, with the circumstances of India at all—that I might assume to be possessed by an audience which I now address for the first time. I am conscious, on the one hand, that toiling incessantly for several months at one subject, and that a wide one, complicated with varied and voluminous detail, one's mind is apt to become subdued, like the dyer's hand, to that it works in. Thus, one begins to suppose that topics handled every day by oneself are equally familiar to others not under this necessity. On the other hand, there are probably many amongst you who know more than I am able to tell about India and its administration, and of such I crave indulgence for introducing, from time to time, information which must be trite and commonplace to them, but which helps, I hope, to explain to the rest the peculiarities of census-taking in circumstances

so widely different from those of the United Kingdom, or any other European country.

With these introductory remarks, I proceed at once to my subject by pointing out that a census, even reduced to its simplest form, that of the mere enumeration of the population by head, is far more necessary in India than in countries more advanced in that collection of attributes which we call civilisation. Without this operation there is no standard whereby we can periodically measure the growth, decrease, and migration or what is generally known, comprehensively, as the movement of the population. Every country presents special features in this movement, which for reasons political or social, it is incumbent upon the administration to watch most carefully. In some it is emigration, as in the German Empire, Italy, and Ireland. In others, for instance, Canada and the United States, the influence of foreign-born population, and in the latter, the gradual shifting also of the burden of the land from the East towards the West, and the growth of certain classes amongst the native-born themselves. In England, as we are all aware, one of the foremost questions of the day is the gradual accretion to the urban populations and the depletion of the purely agricultural tracts, facts which, were it not for a census, would be left but partially appreciated, and possibly, therefore, subjected to inadequate remedies. It may be urged, of course, that the registration of births, deaths, emigration and immigration, gives a sufficiently accurate view of the movement of the population to render a special enumeration superfluous, but, unfortunately, in no country has registration hitherto reached this pitch of completeness. In the United Kingdom, as a whole, the calculated population rose very materially above the figure actually found at last census, and for local purposes the error is generally so great as to render the calculation of little practical value. In India, I may remark in passing, registration of births specially is so imperfect, even in many of the large towns, that except in one or two provinces, little or no attempt is made to utilise the returns in calculating an annual rate of what is known as the "normal" increase, the excess, that is of births over deaths. The administration is, therefore, able, during the intercensal period, to perceive, but not to measure or appreciate, any special movement in the population, and the natural growth is barely even noticed.

The census, then, being one of the touchstones of the administration, and the only true means of measuring the movement of the population, the question naturally arises, how often should it be applied? The obvious answer is, at the intervals indicated by the conditions of the country, and not in accordance with any hard and fast rule. Practice varies between an interval of five and one of ten years, the decimal system having its conventional advantages. In an old country filling up very fast, or, at all events, with a brisk movement, as in Germany, or a peculiar one as in France, the shorter period is likely to be the more useful. In a country like the United States, for instance, where the population has lots of room to grow in, and, I may add, in my opinion, in India also, a ten years' interval is not excessive. For the United Kingdom, the opinion of experts in economical and vital statistics is in favour of the shorter period. This last, too, was the one adopted by the ancient Romans; but, then, that eminently practical, though overquoted, people were not content with the mere heads and so on, but made their census returns one of property in land, and beeves as well as slaves and other chattels, and on this the owner's assessment was based for the succeeding five years. The connection between enumeration and subsequent taxation, which has long been, and probably still is, a cardinal notion amongst the people of India, has thus classical authority for its basis. The terms are even interchangeable: as we read that Cæsar Augustus, on one occasion, "ordered that all the world should be *taxed*," an edict which, in its simple comprehensiveness, somewhat reminds us of the utterances of a neighbouring Cæsar nearer our own day. Another point of resemblance, I may casually observe, between that incident and the notion I have found very generally held amongst natives of India, especially landholders, is, that Augustus's census was one of the population *de jure*, that is, domiciled at or belonging to a place, not the population *de facto*, found residing in a place at the time of enumeration. Joseph, that is, had to go to be enumerated in Bethlehem. Now the class I have mentioned almost always endeavour, when they have been away from home for a while, to be in their own house for the census, so that they may be counted amongst their own people. Augustus had, no doubt, a very different object in view, but with that we are not now concerned. Anyhow, this quinquennial census amongst the Romans was the origin of a word we have adopted into

our own language when we talk of a lustre, meaning five years. After the Roman proprietor had returned the value of his estate in the census paper, he went and formally washed—performed a lustration, or ceremonial ablution. Whether this was the equivalent of our modern, but, I believe, decaying tribute of conscience-money, or whether it was the only time the Roman washed in state, I do not know, but it was a process sufficiently solemn to require a special name.

Granted, then, that whilst a census every five years is advisable for England, France, and Germany, one every decade is enough for India. The next question that arises is, whether the enumeration should be synchronous all over the country; that is, taken on a single night, as in the United Kingdom and most European states, or spread over several days, or even weeks, as in the United States of America. Where the count is of heads only, or where a simple schedule only has to be returned, and the main object is to get these requirements correctly, especially the former, there seems to be no doubt that the census should be taken throughout the country at one and the same time. By so doing, a photograph, as it were, is obtained of the population as it existed at the time fixed, and every one is counted where he happened to be, irrespective of nationality or domicile. On the other hand, where the census comprises an inquiry into industries, mines, property, and so on, as in the United States, it is out of the question to combine it with a synchronous count of the population, and this is the more to be regretted in the above States, as there is not any general or uniform system of registration of births and deaths there, so that, as in India, it is only every ten years or so, that the movement of the population is recorded. Against the synchronous system, however, there is this strong argument to be urged, that however simple the inquiry, and however extended may be the literacy of the population, the process entails the employment of a large staff of enumerators to distribute, help in filling up and to collect the schedules, but the superior accuracy of the results repays the cost. In India, a synchronous census was prescribed, and with the exception of a few tracts, the operations were conducted on that plan. The exceptions were, first, hill-country covered with forest and infested by wild beasts, where enumerators would not go by night; secondly, thinly populated desert tracts, where the enumerators could not go; thirdly, the trans-Himalayan portions of the Punjab and Kashmir, from which the enumerators could not get out till the passes opened in July; and lastly, tracts which might have been enumerated by night had there been enough men at hand competent to undertake the rôle of enumerator. The entire population, however, of all three exempted classes was small compared to the whole tale, and as it is naturally of a stay-at-home order, it was unlikely to be omitted or to get confused with the rest, in the way of double-counts.

The task of preparing the ground for a synchronous census is one, I may say, that must be tried before its extent and troubles can be thoroughly understood. There are not only general outlines to be traced, and instructions framed to fill in the details; but once these are issued, there follows the far more difficult, lengthy, and anxious task of seeing that they are understood and correctly applied. Whatever the experience of the man who drafts the rules, and the care he takes in getting them of the widest scope practicable, they are hardly in the hands of the people who are to work by them, than the rain of anomalies and "hard cases" begins to pour down. The worst of it is, that in the majority of such references, the difficulty is a real one, and has to be faced without question of precedent, since it probably was never thought of till it crops up in the course of the preparations, often, doubtless, comparatively close on to the actual census. I am not now speaking of India only, but of other countries as well, since the rules and reports I have seen from various census officers show that, in a more or less aggravated form, the difficulty of organisation is universal. In India, though we have peculiar obstacles in the way of preparatory measures, I am thankful to say that we have compensating advantages. To attempt to take a general census of that country on the same lines as are laid down for the United Kingdom would entail charges that would inevitably lead to the abandonment of the undertaking altogether. I should explain, perhaps, that in the stage of the operations with which I am at present dealing, the actual number of the people to be enumerated does not, as a rule, and certainly not in India, tell upon the cost of the census to the same relative degree as it does once the census is taken. The main difficulty in arranging for the census in India is not the mass of people to be dealt with, or the large area over which it is spread, but the

variety of circumstances severally requiring special consideration. It is not, as we have probably often heard, one country, but a small continent, differing every few hundred miles in physical features, in language and religion, or, at least, in the mixture and predominance of religions, as well as in the class and temperament of the inhabitants, and in political circumstances. Of this I may have more to say later, but, for the sake of clearing the course for the present of statistics, I may mention that against the 37,740,000 people of the United Kingdom, we are now concerned with 287,000,000. I think it is Professor Seeley who has said that after a certain limit, figures cease to convey any impression, and the above quoted round numbers have certainly an astronomical flavour about them. I will quote, however, the exact figure, namely 287,232,877, because, if a certain French writer, whose name I forget, is right in his appraisement of the public judgment on statistics, the concluding seventy and seven of the above sum will carry more conviction in favour of the magnitude of the Indian census than all the other 287,232,800 put together.

It has for some years been an object with certain statists of Imperial views to have the decennial census taken throughout the British Empire on one and the same date, and no doubt where the colonies are near together or to the mother country such a measure would, apart from sentiment, have a beneficial result on the accuracy of the enumeration. But so far as India is concerned, the number of persons admittedly enumerated at each end of the voyage, and thus appearing in both the Indian and English return, is insignificant, whilst to take the census of the former country late in the spring, when the enumeration takes place in the United Kingdom, would be highly inconvenient to the extent of endangering the correctness of the results over a great, if not the greater, portion of India. There is, of course, the comparatively minor consideration of keeping the intercensal period as near ten years as possible, and in India the enumeration took place towards the middle, or end of February in both 1881 and 1891, and in many provinces, in 1872 also. The two former, however, are the only instances of a census generally synchronous throughout the country. But the main arguments in favour of taking the Indian census in February are not statistical, but local. During that month the cultivating classes are usually at home, except for the few days before and after the full moon, when they are prone to enjoy a pilgrimage to some neighbouring hill or river. In Burma the rice harvest is over, or nearly so. In the North of India the cold is still sufficient to prevent wayfarers from travelling by night on the high roads, and the months most fortunate for marriages and their accompanying festivities have not yet begun. Again, later on, the heat would make it almost impossible for that inspection of preliminaries, which I will afterward show to be necessary, to be undertaken with sufficient energy and persistency. In the forest tracts, too, it would be still more dangerous to move about than in the colder season, and throughout the greater part of India the harvesting of the later crop would be in progress, whole families would be encamped on their fields or threshing-floors, and others would move about in gangs for reaping-engagements, miles from their homes. Altogether, taking the circumstances of all the different provinces together, a date not earlier than the 15th or later than the end of February seems to be the most suitable. In 1861, the census was taken on the 17th, and, in 1891, on the 26th of that month.

The date once fixed, the preparations have to be taken in hand, and these began in the provinces on this occasion ten months before the census. In anticipation, however, of provincial action, the whole plan of the census campaign had to be drawn up, rules framed, and forms of schedules and returns devised and published. The scheme adopted was based on that of the preceding census, with such modifications as experience suggested. The operations of 1881, being the first of their kind undertaken in India, were, of course, to a great extent, tentative; and, as nine or ten of the officers who had superintended provincial operations on that occasion were still in the country—of whom I was myself one—we followed the suggestion of my predecessor, Sir William Chichele Plowden, and held a conference well before the time when the results of our deliberations were required to be put into practice. Working on a digest of the 1881 rules and procedure, which it fell to me to prepare, we threshed out a complete code for use in 1891. I need hardly say that the lapse of nine years had deadened, if not obliterated, the effects of the pinching of the 1881 shoe; but the looking over our old forms and rules brought vividly back the memory thereof, and we were thus enabled, I hope, to cobble up a better fit for our successors,

instead of inflicting on them, as we had ourselves been obliged to undergo the trouble of wearing into shape a brand-new article on the Procrustean model of the ammunition-boot, which is guaranteed to fit all customers. As soon as our proposals had received the approval of the Government of India, which was given after consultation with the authorities of each province, the real work began. A Superintendent of Census Operations was appointed for each province early in April, 1890. He was, generally speaking, an officer selected from what is called the district or revenue staff, of some years' experience of the language and customs of the people, as well as of the system of administration, from the village upwards. In one case only was it necessary to find a superintendent from the staff of a neighbouring province, and this was owing to the temporary paucity of district officers on duty. The post of superintendent of a census is one of some delicacy, requiring considerable tact as well as knowledge of the people, and above all things, physical toughness. It might be expected that I should add statistical knowledge or aptitudes, but I must confess to a preference for the administrative faculty, with, of course, due deference for accuracy in the matter of two and two. The greater part of the statistics collected at an Indian census are intended for current reference by men who only want to be certain that the figures carry their meaning on the surface, and that where they are incomplete or partial, the origin and extent of the defect is made clear, and explained along with the tables themselves. The common gibe as to the fallaciousness of figures rests entirely on the fact that the latter are nearly as often abused as used in public discussion, since there seem to be few collections of statistics of any considerable scope or extent, which can be taken neat-undiluted, that is, without copious explanations. What I may call the esoteric branches of statistics, with which, however, I do not propose to trouble you, can only be safely dealt with in the mass, collating and examining the numerous distinctions that go to form a more or less consistent whole. But this is a digression from my subject, which is the qualification of an administrator of the census work. He must have tact, as amongst other things he is usually junior to the heads of districts, whose arrangements he has to criticise and bring into harmony with the general lines laid down for the enumeration. Knowledge of the people is necessary, in order that he may frame rules and illustrations on purely local points where error is likely to occur, and avoid offence to religious or caste feelings. He must be physically sound, as the strain, especially for a month or two before the census, is remarkably hard, and even before that time, the amount of local inspection and travelling about on district consultations through the hot and rainy seasons, is no child's play. I must not conclude this portion of my subject without mentioning how much the value of the enumeration in 1891 was enhanced by the trouble personally taken by all the superintendents to show that every detail in the preparatory arrangement was in efficient working order, and by their success in enlisting the full co-operation of the district officials through whom they worked.

But I find that I have omitted to describe what the duties of the superintendent really are, and to do so is necessary, though I will make my remarks as short as possible. To summarise his work, he is bound to arrange that no one in his province shall escape enumeration on the one hand, or be enumerated more than once on the other. The unit of district administration throughout the greater part of India being the village, it is with this that the census registration began. Villages were grouped into circles, each under an inspector or supervisor. In Bengal, and parts of Assam, however, where the village-system has been dissolved in favour of estates, the superintendent has to begin a stage further back than elsewhere, and obtain a list of what are considered villages in each police or revenue subdivision. Next comes the demarcation of the village, or group of villages, into areas to be placed under an enumerator, technically called blocks. In towns the corresponding registration took place by wards, or other subdivisions, but the system was everywhere uniformly adopted. The houses in each block were then serially numbered and registered, under strict supervision, and the resulting register, when finally passed, was the basis of enumeration. From the above description it will be seen, that except perhaps in a few parts of the country, there is less chance in India than in England that any considerable collection of residences will escape enumeration. In England the artificial boundaries are not only numerous but bear no relation to each other, whereas in India the subdivision can always, with the exceptions I have just mentioned, be reduced to its lowest term—the village. Allowing, then, the greater convenience, for census purposes, of the village in

India over the parish in England, I must admit that, so far as statistics of houses go, the former is far inferior. In England the definition adopted for a house is universally applicable, and, if supplemented by that of a tenement, all necessary statistics can be readily obtained at the census. But in India, the variety of dwelling and in the domestic habits of the people is so great, that no one definition can be framed that will apply throughout the country. It is very doubtful if even in a single province the local definition is uniformly applicable; so that in the towns of Calcutta, Bombay, Rangoon, and probably Madras, alone, are the statistics regarding house-room really valuable. For all practical purposes connected with the enumeration it was enough that every building should have a number affixed to it, so that it could not be passed over; but under such a system the wattle and daub-hovel, a few feet square, and the castle-like enclosure of the village magnate, containing over 100 people, appeared in the register as in the same category. As I said above, this was inevitable, and though provincial, or at least divisional, uniformity may have been in many cases secured, it is labour wasted to make use of the return of houses in a review of the whole country.

Returning to the preparatory measures, I have to add that in supplement to the arrangements for towns and villages, the provincial census officer had to see that travellers by road, river, and rail, were duly enumerated, and to provide a staff for taking the census of vessels, not only those actually in harbour on the census night, but coasters arriving afterwards without having been caught at any other place of call. For all such cases general rules were issued from the central office, and local modifications made as each case demanded. The rules, I may remark, about railway travellers, give considerable trouble in India on account of the length of the journeys, and though on the whole they worked efficiently, I have become aware of instances even within the circle of my own acquaintance, in which, from excess of zeal the same person was presented with from three to four schedules at different parts of the line. The general practice was to enumerate passengers as they alighted during census night, and to turn out the whole lot remaining at six o'clock the next morning, and enumerate them before letting the train proceed. I heard no complaints about the delay. In England it would have been otherwise!

Concurrently with these arrangements for registration and so on, the superintendent had to look after the preparation and issue of schedules: and here again we have a point in which India is at a great disadvantage compared with England. The form of schedule and the code of instructions for filling it up were uniform all over the country, barring the examples and illustrations, which had to be made up to suit the locality. But then arose the difficulty of translation of both rules and headings, for in India the census is taken in at least seventeen languages, several of which require forms in more than one character. In England, a few schedules in Welsh were all that were not printed in a single language. The diction, moreover, into which the forms were rendered must be that of the vulgar, because the style of translation which commends itself to the official scholar is as often as not unintelligible to one not acquainted with the language of the original. To meet this difficulty the provincial superintendent took into counsel that universal referee the "experienced district officer," and I believe got, as usual, what was wanted out of him. Then again, the examination of the indents for forms and the despatch to each district was an immense undertaking, since very often, if not usually, a great many more were, through caution, asked for than were actually wanted. As it is, a rough calculation indicates that between eighty and ninety millions were issued. Taking only those that were probably used, we find that they weighed about 290 tons, and would cover, if spread out, an area of 1,300 acres, and if put end to end, again, would stretch over 15,000 miles, or more than from India to England and back. All this mass, except the few demands which, as always happens on such occasions, come in by despairing telegrams close to the census time, had to be printed, despatched and distributed to local centres by the end of December. It was dealt with by the Government presses, except in a few instances, where lithography had to be used, and I must add, with the greatest possible economy, punctuality, and efficiency in every respect.

This narrative, which I fear is becoming tedious in its detail, has now reached the point when the enumeration itself is in question. Here we diverge altogether from the English system. In England, as you know, the schedule is left with each householder a few days before the census, and an enumerator recovers it, fully filled in, the day after. If

the householder is unable to fill it up himself, he is instructed to invoke the aid of some competent neighbour, but the whole onus of the return falls on him, and the enumerator is practically responsible for only distributing and collecting in full tale the schedules for his beat. In India, on the other hand, this system can be made applicable to none but the comparatively small European element in the population, and to native gentlemen, high in rank or official position. In the city of Bombay alone has it been in force throughout the community for the last three enumerations. The mixture of races and languages in that town is, no doubt, a strong argument in its favour, and the error in detail in 1891 was less than I should have expected from my experience ten and nineteen years before, on both of which occasions I happened to be in Bombay on the census night. The standard of education, however, is, of course, a good deal higher there than in the rural tracts and smaller towns. In the United Kingdom, I suppose, not more than five or six householders in a hundred are now unable to fill in their schedule, but in India the proportion must be reversed. In fact, I doubt, if taking the number who can read and write, and discounting those of them who are not capable of comprehending the rules for filling the return, you will find two in a hundred who could be trusted with this duty, and the literate amongst their neighbours would not *ex hypothesi* be numerous enough to undertake to do it for them. There are whole tracts of country in different parts of India, both British and feudatory, where there is not a single person within miles who can even sign his name, except the village accountant and the local money-lender. In such cases it is necessary, of course, for the State to undertake the whole responsibility of the census, and the burden is thrown accordingly on the accountant, to whom the money-lender, in the circumstances, affords most useful and gratuitous aid. But it is the same, to a greater or less extent, all over India. A schedule left for three days in the house of nine out of ten of the population would be mislaid in a hole in the tiles or thatching, or strangely plaited and tied up, like a court summons, in a corner of the householder's waistcloth, or again stuck, like a turnpike ticket, into the folds of his turban, and forgotten. The tenth man would probably spend some happy minutes, not inaudibly, in discussing its legality with the enumerator, or return it endorsed casually with the primitive addition sums necessary to the balancing of his day-book. This might not be the case in Burma, but I do not think that even there the returns would be properly made. The general result is that the schedules are not left in the charge of householders at all. The duly appointed enumerator of the block has them all bound into books of convenient size, with the rules in the beginning and the numbered-list of houses at the end, and a printed sample or two of schedules filled up in illustration of the more knotty points raised in the instructions. By the way, with reference to these illustrations, an amusing incident was told me by one of the provincial superintendents. He had found during his inspection the same class of misconceptions uniformly running through so many districts that he embodied them all in a printed schedule, which was circulated, with a note, explaining each error. Shortly afterwards he received an urgent appeal from one of the officials engaged in arranging for the district census, imploring the superintendent to withhold the said illustrative schedule from publication, as it contained several serious mistakes, correction of which accompanied the communication! I remember a similar case years ago, in which the head master of a high school prepared an essay containing, in italics, all the errors in English most common amongst his pupils. This was taken for some time as a model of composition, and followed with fidelity. Moral: illustrations and samples are not always instructive.

To return to our enumerator. It is obvious that if he has to fill in an elaborate schedule for each household, the latter numbering from three to fifty persons, he can only get over about a dozen, at most, in a night, even without reckoning the time wasted in extracting the information required, and in getting down in the return all the babies, unmarried girls, and old women, who would be left unmentioned if the householder had his way. So that, at this rate, the night census of our 287,000,000, more or less, would require over 4,500,000 of enumerators. Now, the total number of persons of fifteen years and upwards who can read and write at all in the 262,000,000 odd, from whom the information was demanded, is about 11,340,000, and allowing about the same proportion in the rest of the country, which is more than is due, we have an adult literate congregation of 12,500,000, on which the demand for enume-

rators would have fallen to the extent of about one in three.

To avoid this difficulty, in the first place, the average size of a block in rural tracts and small towns was fixed at 60 houses, or about 300 persons. We thus required not more than 950,000 enumerators, instead of 4,500,000. Secondly—and this I must impress upon you is the cardinal point in the whole census-taking—the enumerator, at a certain varying interval before the census, went round his block, and filled up all his schedules for the ordinary residents of each house, and for such sojourners as were not likely to leave before the census night. He was not bound to enter a lot of guests and visitors simply stopping a few days for a marriage or pilgrimage, or come shopping from neighbouring villages, as all these, under the rules, would be registered by the enumerator of their own block as if they were present, since their family or neighbours would tell him that they would be back for the census. Thus, not only was nearly the whole census—in fact, the whole of that of the ordinary population of a place—taken in anticipation of the synchronous operation, but the interval afforded time for a most expensive and thorough inspection of the enumerators' work by both district and census officers. In this way, the rules were illustrated in their actual working, and the results were, on the whole, most conducive to accuracy of detail. Personally, I had the opportunity of seeing this part of the enumeration in many towns of the North-West Provinces, Oudh, the Punjab, Sindh, the Central Provinces, and Bombay, from the Khaibar to the sea, and it gave me an excellent notion of the quality of the work and the direction which statistical errors were most likely to take. After this inspection by the local census officers, all the enumerator had to do was to go over his register again on the census night at each house, and bring the return up to date by striking out the entries of the inmates who had died or departed since he was there before, and entering those who had been born since or who had come to the house as visitors. These alterations were made in red ink, so that they could be easily checked, and a good supervisor could tell very soon thereby whether the enumerator had really visited his block thoroughly or not. My impression is that in towns the final check was invariably done in accordance with the rules; in ordinary villages, too, this was generally the case, whilst in scattered villages probably the round of the houses was made on the afternoon preceding the census night and the early morning following it, and the evening was reserved for entrapping travellers and vagrants, or in discussing the schedules with the local elders in the village meeting-place. Now from the description I have given of our plan of procedure, it will be seen that there is practically a double enumeration, one original, the second a test of it, so that the chances of accuracy are very good, as Sir Richard Temple pointed out in a recent article he published in the *Fortnightly Review*. The system adopted has also all the advantages of the non-synchronous enumeration, and still keeps intact the main object of simultaneous registration, namely the prevention of omission or double-counting. It seems, on the whole, the best, even if not the only system that could be carried out in India, but it is clearly unsuited for countries where clerical labour is expensive, or the body of state officials comparatively small. One of the great advantages India possesses in connection with operations of this nature is the village system. I have already mentioned how it helps in mapping out the country into areas for census enumeration and supervision; I have now to add that it provides the bulk of the agency available for that purpose. In provinces and states where this system is in force, all statistics of births and deaths, vaccination, diseases, crops, cultivation, revenue, boundaries, and I dare say other matters are traceable to their source in the village accountant. In Bengal and the neighbouring districts of Assam, I believe, the local constable or watchman is the purveyor of information on most of these subjects, and the census had to look elsewhere for its staff. West and south of Bengal, however, the accountant who enlisted the services of his family, some of whom were usually in training for the post; the village schoolmaster, when there was one, and some of his elder pupils; the local grocer and his writer; and, in towns, the municipal commissioners, their relatives, clerks, and the corporation establishment, constituted the bulk of the census officers, with the addition of every Government clerk who could be spared for a couple of days before and after the census night. In most provinces, too, very efficient aid was gratuitously given by all non-official classes, especially in supervising the carrying out of the published rules, so that comparatively little expense was incurred on account of agency. It was made a rule, too, that every one should

be given a beat as near as possible to his own residence, so that he could give his services more conveniently to himself, and without interfering with his other avocations. There were cases, of course, in which specially engaged enumerators had to be despatched long distances into wild and unhealthy tracts. These men were well paid, but their number was kept down as much as possible, both to reduce expenses and to get the work done better, since it was found that greater accuracy was to be got out of the regular staff, working non-synchronously, than by employing for a few days a lot of irresponsible hands, who dreaded the jungles and despised the inhabitants thereof, and whose main object was to get back home as soon as they could, and touch their reward. The instruction and drilling of this army of enumerators was a matter that required much attention and time, especially as the superior census officers had first to be put through the same mill, in order that they might appreciate the difficulties of the task, and understand the details of the rules. The usual plan was for one of the district staff to take a class of the supervisors round a few houses, and enumerate the inhabitants, either before or through his pupils. Or, again, witnesses or applicants present in a court or at a magistrate's camp were pressed into services as subjects. The servants, clerks, and messengers of some of the superintendents were so often put through the process, by way of illustration, that they got to be quite experts in the schedule, and no doubt made excellent enumerators when the time came.

We have now traced, vicariously, the path of census administration up to the point at which the returns have been obtained. Here we cease our dealings with the public, and the technical part of the work begins, in which the new material is worked into statistical form. Before I enter upon the scope of the inquiry, I had better finish with the enumerators, for their job was not quite over when they had completed their round on the census night. First, they had to repair to the head-quarter village of their circle or ward, as the case might be, and there have their books of schedules examined and passed by their superiors. There were generally about ten blocks in a circle, and as soon as a book was examined, it was returned to the enumerator, who totalled the population by sex, and then the occupied houses, and passed the results to the supervisor on a slip of paper. The book was then made over to a second enumerator, who did the same addition. If the two results tallied, the totals were entered in the form kept for the circle, as well as on a slip attached to the book. The circle was then totalled, and the result brought to the sub-divisional head-quarters, from which it was sent in a second edition of the slip to the district centre, and the district population, when compiled therefrom, was telegraphed to me in Simla, confirmed in a detailed slip, sent by post. A duplicate was also sent to the Provincial Census Officer.

The number of districts in India and Burma is, or rather was in February, 1892 (for some changes have been made since), about 250, and of states and agencies communicating direct about 100. Added to these were 60 or 70 large towns, and all the correcting and revising messages. Telegrams began to arrive on the second day after the census, and for the next fortnight they pattered in at the rate of from five to 40 a day. The exuberant zeal of some officials led them to class their communications as "urgent," which, according to Indian rule, compels the telegraph office to deliver them at once by special messsenger. I had visions of this beforehand, and had warned the office that the Census Commissioner was worthy of his repose, and that nothing was urgent after his office was closed for the day. I fear, however, that my assistant, who had not thought of this precaution, must have passed several disturbed nights, as the telegraph officials doubtless felt bound by rule to deliver urgent messages somewhere or other, and, therefore, shot them out on him.

I now pass on to an entirely different topic, namely, the information required at the census. There are certain subjects which, it has been argued at various international statistical conferences, should be invariably included in a schedule, and of these the most important are age and sex, which enter, also, into most of the other branches of census statistics. In India, especially, where the results of famine often seriously disturb the balance of both in their normal distribution, the comparison between two enumerations is both valuable and interesting, since even though the ages may be anything but correctly returned, the misstatements are probably on the same lines on both occasions. Again, in most countries a return is made of the single, married, and widowed. In one country I know of, the census goes further, and tabulates the divorced, and also those separated from bed and board; but we were

content with the three normal conditions in India, and even divorce, which had to be provided for in the rules, was not found susceptible of uniform treatment. In one province it was returned under widowed, which is correct according to the instructions, in another it was either not mentioned at all, or the divorced were returned as married. Yet it is a recognised condition and of no rare occurrence. These returns of civil condition in India are of some importance owing to the widely different marriage systems which are found in that country, and to the possible effect of some of them on the physical and moral character of the people who follow them. They have been somewhat prominently brought into question during the last two or three years, owing to legislative action, past and present, and the result of the census will no doubt, in respect to the returns on this subject, be widely and carefully scrutinised, but they do not fall within the scope of my present paper.

A return of birthplace may be included amongst those classed as necessary at every census. Apart from any question of a nationality or allegiance, the recruitment of the population from outside, and migration within the country, are both important subjects, particularly in India, which presents the extremes of both density and paucity of population. It receives, too, on the east the pressure of a foreign population notorious for its immigrating instinct, and on the opposite frontier is colonised by a race whose sympathies are not always with those who would rule over them. It was, therefore, decided to obtain a return of birthplace by districts for each province and its contiguous neighbours, and by provinces for the rest of the country. This gives the means of judging of the immigration from one district into another, and as the return is by sex, it will show whether the movement is real or merely the usual interchange by marriage according to the Hindu custom of seeking a wife from another village more or less distant. It is also useful to see the extent to which the districts of the province contribute towards the population of the large seaport cities, since the latter are notoriously largely maintained from outside. A subsidiary matter in connection with such a return is that from it can be seen, so far as the province and its neighbours are concerned, which districts or states are the chief exporters of their males, and which, on the contrary, provide resources for all their indigenous sons within their limits. In time, with a population so varied in race, language, and religion, and a country differing so widely in different parts in fertility and resources, a return of this description yields a complete harvest of valuable information, provided sufficient time be given to its exploration.

The question of returning parent tongue at the census was finally decided in favour of retention of the column in the schedule, though it was not suggested that the object with which it was originally introduced, namely, that its connection with birthplace might help in deciding nationality, should be kept in view. It is to be tabulated, accordingly, from a philological standpoint, simply as indicative of the relative strength and the various synonyms of the numerous languages and dialects found in India. There are possibly a few instances of overlapping languages in which it may be useful to ascertain how far one has been getting predominance over the other during the decade, but the chances are that a question of this sort will have been settled between the district and the educational authorities without any need of census information.

The question of nationality, which I have just mentioned, was settled by using that term in schedules issued to European foreigners, in whose case alone is the information ever required. In the vernacular editions, the column was headed sub-caste or class, and in the triglott schedules used in Bombay city, this led to some curious confusion between the terms amongst the English-knowing non-European population. In the same way, the word race was used in the English form, and caste or tribe in the vernacular; and, I may say, the returns under these two columns together added a very considerable amount to the labour and expense of dealing with the results of the census, as the confusion between the two was almost inextricable without referring right back to the original schedule to see what the individual really meant. The whole question of caste and tribe in India is such a wide one, that it will be out of the question for me to enter upon it in this place. For the information of those of you who are acquainted with the caste system, I may state that in addition to the return of the strength of each caste, the series of caste-tables includes one showing the four selected infirmities, of which I have still to speak, by caste; also those who know how to read and write by caste, distinguishing those who know English from the rest; and, finally, though not for the whole of India, a statement show-

ing marriage statistics for each caste by different age periods, indicating those where infant marriage and widow re-marriage, &c., are respectively prevalent, and the different provincial or territorial custom in those respects. I need not tell those whom I am now specially addressing that this series is a very bulky one, though, I must add, that save within broad limits, it is not likely that the information can be welded into an imperial total of much value, but must be made use of by uniform groups or in its provincial form.

The return of infirmities which I spoke of in connection with caste, comprises two tables, one showing the infirmity by age for each sex, the second that by caste, just mentioned. The four infirmities selected for inquiry are unsoundness of mind, that is both lunacy and imbecility, congenital deaf-muteness, blindness, and leprosy. I fear the returns are far from complete, but in this our census does not much differ from that of other countries. For instance, it is difficult to get the deaf and dumb separated into congenital and others. Blindness I fear, too often includes the one-eyed, in spite of there being a special and different name for the latter. Leprosy is a term which has unfortunately been associated in the case of an Oriental, with whiteness of skin, from Gehazi downwards, so that possibly, though every means were taken to prevent it, leukodermacy has, though in comparatively few cases perhaps, passed into the return with the true disease. Moreover, as to leprosy, either women are not effected to anything like the same extent as men in India, or there has been serious concealment of the disease amongst the former sex, for the disproportion between the two is astonishing. This, however, is another question concerning the results of the census, which like the former, must be set on one side for the present.

A further subject on which information is collected in India in accordance with the custom in a few Occidental countries, is that of education, or rather degree of instruction. We used three heads, those who are under instruction, those who are not, but can read and write, and those who are not, and cannot. These are returned under three age-periods, though unfortunately the latter, which are based on fives, do not commend themselves to the educational authorities, who have selected multiples of six for their statistics. Considering the general quality of Indian age-returns, I do not think the difference is material. Probably the chances are equal that a person returned as 5 is 6 or 4; 12 again, is far too favourite an age in our return, at the expense of 11 to 14, and 18 is possibly used as the equivalent of anything between 16 and 19. I I think, too that we of the census conference were injudicious in recognising those under instruction at all, and that a more useful return would have resulted had the distinction been simply between those who can read and write and those who cannot. I have mentioned above that this general return is supplemented by caste details, so far as those are concerned who can read and write. This is with a view of ascertaining how far down the social scale, which is fairly enough measured by caste, has this degree of instruction penetrated; and also, in the same way, amongst what castes is the knowledge of English found, and in what proportion to the total number who can read and write.

There remain two subjects, occupation and religion. As to the first, statistical opinion is divided regarding the value of a census return. Experience in some countries has shown that the subject can only be properly treated by a special inquiry, more minute than can be obtained at a census. Others hold that, by dint of instructions and supplementary columns, a valuable amount of information can be got on to the schedule. I am inclined to range myself in the former camp, as I fear the best census return will always contain misleading figures, and that, too, with reference to perhaps some of the most important occupations. The return in 1881 was considered by most of us who had the handling of it so inadequate as to the number of persons engaged in the different occupations that we recommended that the distinction between worker and dependent should be dropped, save as a salve to certain prejudices which would object to the ascription to a woman of a distinctively male occupation, and *vice versâ*. Our suggestion was accepted by the Government of India, and the occupation return contains against each entry the males, females, and both combined, for town and country severally, under suitable age-periods. Thus the grand total of these facts shows the number of persons living by a certain occupation, whether they work at it themselves or are supported without working by some one else who works at it. The results remain to be analysed, till the completion of which process my judgment remains in suspense on the value of the return.

As regards religions, which are not recorded

at the census of England, the Indian return is of interest in several ways, and of practical value in some. The Mussulman, Zoroastrian, Jew, Christian, and Buddhist, are all well defined, and comparison with former enumerations is possible and probably accurate. But when we come to Sikhs, Jains, and Hindus, and get down to the religions of forest tribes, which last have been tabulated under the collective title of animistic, we enter territories the boundaries of which are as undefined as those of the Pamir or Upper Burma. The outskirts of Hinduism, especially, are as uncertain as the course of exchange. There is no doubt that Brahmists, and the newly-found title of Aryan may for all practical purposes be considered as still within the fold. Jains, too, have been known to return their religion as Hindu, but of the Jain sect. Sikhs are better defined, but the distinction, except perhaps amongst the fighting classes, is a good deal one of ritual. As for the Forest tribes, except in and near Burma, it is often impossible to state where Hinduism ends and the fetich, or tribal form of worship, begins. The former, in fact, only seems to acquire cohesion when placed in antithesis to Islam, and in parts of the Punjab the lower classes do not seem to be dogmatically sound even in this respect. The relative strength in the towns of the north, of Hindu, Mussulman, and Sikh, is a detail often requiring attention. In fact, in almost every large town in India the tabulation of the two former may be of use. The antagonism of the two creeds is always in existence amongst some classes of the community, and a very small local circumstance may turn out to be the very match required to kindle it.

I think I have now traversed the whole field of the census inquiry, and have sufficiently shown what it was that we set before ourselves to do, and how we arranged to do it. All that I have left untouched are the expenses, and the purely technical processes through which the returns pass from the individual entry in the schedule to the aggregate of the provincial or Imperial total. These last are highly complicated, and I will ask you to take my word for it that they are exceedingly uninteresting, especially to one who has just been engaged in winding them up. They are also the most expensive section of the operations, and this is the less satisfactory, because most of the cost is incurred for the sake of insuring by revision the accuracy in tabulation which one inexperienced in such matters might reasonably presume would be attained in the original work. They also cause perhaps more anxiety even than the enumeration, because the operations are more concentrated, and the means of check and correction are always available, and sometimes misused by a trusted subordinate. Last, but not least, they afford the fullest opportunity to the Census Commissioner, awaiting the provincial returns in the Olympian atmosphere of Simla, to become disagreeably importunate.

We have come now to the climax of all public entertainments, the bill. It will not need the classic quarter hour of Rabelais to consider, for I hope I have succeeded in showing that what may, at least for the present, be considered an equivalent, has been prepared. Whether digestion will confirm my opinion is a matter of time, for, like Martial, my aim is that the fare should please the guests not the cooks, and the provincial dishes have still to be ordered into an imperial banquet. The total sum falling on the taxpayer in British territory, excluding, that is, the States, but including the whole cost of my own personal share in the operation, is about 25 lakhs of rupees, calculated up to the end of the whole business. But out of this a considerable sum, of say Rs. 50,000, was incurred on account of the smaller and less advanced of those states, so that, in order to arrive at the more or less correct incidence of the charges per head, it is necessary to omit that amount, and restrict the calculation to the provinces alone. By this means you will find that the rate per 1,000 people was as nearly as possible 10½ rupees, that is 14s. 8d., taking the rupee at 1s. 4¾d., which is a fair average for the time when the money was being spent, though, unfortunately for us of the salaried classes, it is so no longer. Ten years ago, the corresponding population dealt with was 195,500,000 as against 217,500,000, and the cost 24½ rupees, so that with a task increased by over 11 per cent., not to mention the very material increase in the amount of information tabulated, the charges remained practically the same. This result is greatly due to the experience gained at the census, with which I have just been comparing that for which I am responsible, and to the warnings of my predecessors, of which due advantage was taken. It is not fair to institute a comparison between the above rates, and that in England, which, in 1881, was £4 18s. 4d., because against the greater mass and complexity of the population with which we have to deal in India must

be set the great advantages we derive from our village staff, and from the fact that the supply of clerical labour, of a sufficiently good quality to be of service in census operations, is, at all events in most of the larger provinces, in excess of the demand. For instance, when the abstracting offices were in full work, we had about 15,000 clerks employed, and by judiciously seconding for a time permanent officials of a certain rank, adequate inspection and supervision were ensured.

I will now conclude this account of the Indian census and its administration with a few remarks of a personal nature. The vital point of census statistics above all others is uniformity, that is, the figures must everywhere represent identical facts, in varying degrees. It is essential, accordingly, that the direction of the operations should be centralised; but it is none the less necessary that the application of the rules thus issued should be identical throughout the country. Now, the circumstances of India are such that it is out of the power of any one man to grasp them all in the detail required for a census, so that much of the responsibility of ensuring uniformity of results was imposed upon the provincial superintendent. For every general rule or instruction issued, and for every form prescribed, the sole responsibility rests on me, but once in the hands of the provincial officer such matters had to be moulded in the local groove best tending towards the desired results, and my position was by no means that of wire-puller, but rather of chief of the staff. Many a thousand miles did I travel, and many if not most of the important cities of India were visited by me in my tours of inspection, and though the experience thus gained must be but superficial, I saw enough to satisfy me that the figures we have collected are based on facts as much in one part of the country as in another, and that on the whole the connection is a very close one. The reviews of their provincial figures by my colleagues, which are now either published or to be issued shortly, prove the interest and value of the results. There is also this to be considered, that such works, each containing, moreover, from 250 to 400 printed pages of closely tested tabular matter, were prepared in from 13 to 15 months of the census, whilst within a month from that date substantially correct figures for over 286,000,000 of people were made available to the public. These results could only be obtained by months of incessant and anxious toil, and the exercise of the best administrative faculties; and all this is evidence abundant that the labourers in both provinces and states were altogether worthy of the magnitude of their task.

DISCUSSION.

Sir WILLIAM PLOWDEN, K.C.S.I., M.P., said he had listened with interest to this account of the difficulties which Mr. Baines had to encounter, and of the successful way in which he had overcome them. The first point which must strike the attention even of those not acquainted with India, was the enormous area and consequent amount of work which had to be done; as shown for instance by the figure of 250 tons of paper used in the schedules. As a former Census Commissioner, he was quite able to realise the truth of this statement, because in the former enumeration in Bengal, Mr. Bourdillon informed him that his papers, not the schedules, but the abstracts which he sent in, would have filled an ordinary luggage-train. The next striking point was the extraordinary success of the operation. To think that in two months after taking the census the public were informed of the total figures enumerated was very remarkable. In the 1881 census, his predecessor, Sir Charles Elliott, and himself, with all their efforts, were unable to get out the figures until late in 1882. He might point out that this was only the second imperial census which had been taken, although the people were thoroughly accustomed to enumerations of this nature. Madras had the most ancient history in that respect, at all events since the British occupation, the enumerations going back for fifty years; but in the North-West Provinces the first census was taken in 1847, and since 1851 it had been repeated at decennial periods. Mr. Baines had remarked on the great facilities given by the village system, and shown how through the village accountant or watchman an immense amount of information was collected continually, and at the beginning of a census a great deal of work was done by these officers for which they were paid little or nothing, though but for their aid the counting of such an enormous population would be utterly impossible, with the details which were included. He had noted the particulars specified by Mr. Baines, some of which were not included in the English returns, viz., age, sex, civil condition, language, race, or nationality, caste, four specified infirmities, condition of education, and religion. One of the principal matters which called for attention was the great difference in the manner in which the information was collected as compared with the practice in England. Here it was essential to success that the schedules should be compiled by the people themselves, the per-centage of those who did not do so being almost infinitely small, but in India it was exactly the reverse; the whole of the enumeration, with the exception of perhaps from 5 to 10 per cent.,

being effected by the enumerators, who first went round and collected the information, and then on the census day finally corrected the schedules. The reason for this was obvious, and appeared on the face of the return which Mr. Baines had already sent in to the India-office, a rough copy of one of which Sir Charles Bernard had kindly given him. The state of education accounted for the whole matter; for it appeared that only about 4 per cent. of those above the age of 15 were able to read and write. Such a state of things would be incredible in England or any western country, but he was glad to say that this per-centage was twice as good as it was ten years ago, showing what rapid strides education was making. The cost of the census was very satisfactory, being only £250,000, or, rather, at the present rate of exchange, about £180,000, which was not a large sum for collecting so much detailed information with regard to a population of 280,000,000. In England the cost was much greater, mainly in consequence of the difference in the value of money. If 125 lakhs were multiplied by six, it would be about a fair comparison, and it would bring the cost to £1,500,000, taking the rupee at 2s., or at the present rate of exchange about £1,100,000. He was glad to see how successful Mr. Baines had been in making use of the experience of the past. In 1881, an enormous amount of difficulty was experienced in various provinces through the officers appointed to superintend the census not having been brought together early enough to make the preliminary arrangements. When Lord Cross consulted him on the appointment of a successor to conduct the 1891 census, feeling how necessary it was that preliminary arrangements should be made in which previous experience should be utilised in order to secure uniformity and accuracy in the returns, he mentioned the names of two of the most efficient provincial enumerators, first, that of Mr. Baines, secondly, that of Mr. Ibbetson, who wrote one of the best reports in 1881, and was now exercising high office in the Punjab. But Mr. Baines was exceedingly successful as the enumerator in Bombay. His report was remarkable for its easy flow of language, its extreme acuteness of observation, and for the grasp it showed of the fact and figures dealt with. The work he had now done showed how fully justified Lord Cross was in conferring the appointment upon him. He only regretted that the present paper did not contain some information as to the results of the census, the most prominent one being the enormous growth of the population, especially in Madras. There had been of late some extraordinary utterances in the House of Commons with regard to the present condition of the population of the province, the exceeding scarcity, and possibly impending famine. There could be no doubt that while in previous years there had been, especially in the neighbourhood of Mysore and parts of Madras, an enormous decrease of population, occasioned partly by famine, but more so by disease following on scarcity, the population of Madras as evidenced by the late census had increased to a much larger extent than that of any other portion of imperial India. That was fair evidence that the statements, hazarded without much knowledge as to the condition of the people, were either entirely unfounded or very much exaggerated. According to the returns he had seen, there was only one part of India where there was the slightest falling off in population, viz., Coorg. He could not understand how it occurred, but the figures were only about 140,000, which showed a slight decrease as compared with 1881. In every other case there had been a steady growth. He believed himself that in all parts of India a healthy progress was going on. A great deal, not worthy of credence, was said as to the poverty-stricken condition of the people of India. He had had a long experience as a district officer, and he must say, going back to the time when he first entered the service in 1852, and the district with which he was most familiar in 1854, to which he afterwards went again as collector, and once again as Commissioner, viz., Meerut, he could see a most marked improvement in the condition of the people in the thirty years which had elapsed. Of course there was poverty there, as there was everywhere, but the people were improving in condition, not only physically, but also morally and socially; and the Government had done much to foster the development of the country. He believed they might fairly look forward to further and further progress.

Surgeon-Major J. M. Cuningham said he was interested rather in the results of the census than in the means by which those results were obtained. He came in the expectation of hearing some of these results, and ventured to hope that next Session they might have a paper from Mr. Baines giving some details of the most important points of the census.

Mr. M. M. Bhownaggree also agreed with the previous speakers that Mr. Baines had given an excellent description of the way in which the census was taken, but thought the paper would have been more interesting if some of the results of the census had been given. He hoped they would be favoured with the same in the course of the next Session; meanwhile he would refer to one important point which had also been mentioned by Sir William Plowden, and that was the state of education in India generally. He thought if some of the funds which were now devoted to what was called higher education were distributed more fairly, and expended on elementary education, there would be a larger per-centage of educated people returned in the census papers. He hoped that would be the case before the next census was taken, ten years hence. It was a matter which did not really fall within the scope of the paper, and therefore he would not dwell at length on it, but at the same time there was a great lesson to be drawn from the results shown by the census on this head; that, while a few selected portions of India could boast of being

educated in the classical literature of both hemispheres, it was deplorable that such vast masses should be returned as entirely uneducated. The future regeneration of India, in great measure, depended not on the high quality of education so much as on the area over which it was spread. He hoped this matter would not be lost sight of by those who guided the destinies of the Indian Empire.

Mr. W. MARTIN WOOD said he had been much interested in the paper, and was glad to find that Mr. Baines had been so successful. The rapid increase of population in Madras, which Sir William Plowden had referred to, must probably be referred to an effort of nature to restore the balance so rudely disturbed by famine, as shown by the census of 1881. He was glad to hear his remarks criticising the statements made as to the general poverty of India. He did not quite follow them; but trusted they would be taken notice of, and that the question should be gone into more thoroughly. With regard to Mr. Bhownaggree's remarks on the small number of literates as compared with the advance in higher education, he thought it was not necessary to put the two branches of education in antagonism to one another. That very small per-centage included the collegians, as well as those who had only the three R's; and it was very undesirable to say anything to further the disposition already shown by the Government and the India Office to restrict the funds devoted to Collegiate education. While so doing, they did not give the funds to the advancement of primary education, but threw the expense of that more and more on the communities themselves. If it were a question of finding funds for primary education, there was an expenditure out of all proportion to these paltry items, which was now being squandered beyond the frontiers of India, thereby straining the resources of the country in every direction; and increasing the anxiety that everyone now feels as to the immediate future.

The CHAIRMAN said they were all much indebted to Mr. Baines for this paper. Something had been said about the paper not giving any of the results of the census, but the fact was, the figures were not yet fully compiled; and it was their compilation and correction which had detained Mr. Baines in India, and so prevented his being present. He hoped, however, in the course of about six weeks, to be in England, and to read a paper before the Statistical Society, and that, before the end of the year, the full census report would be published. Something had been said in the discussion as to the magnitude of the work, and there was no doubt that the taking of a census of 286,000,000 of people and the publication of the results within a few weeks was the biggest thing of the kind ever done. He was very glad that Mr. Baines had brought out the fact that India was a continent of many countries, nations, races, and religions, and it was this diversity of language which made the taking of a census in India so difficult. Something was said about the good work done by the enumerators, and he did think the Government and the people were immensely indebted to them. It was not as if they were employed for one night only, but for weeks and weeks before the counting; and the supervisors, most of whom also were voluntary, and who had previously instructed them, corrected their work. There were about one million of these enumerators, most of them voluntary workers; in Bengal alone 400,000 were employed, of whom less than 200 were paid. It was most creditable to the public spirit of the Indians that they should in this way have undertaken the work, as volunteer officials. It was because all the literate class, non-officials as well as officials, put their backs and hearts into the work that it had been carried through in the way it had. From many sides there was evidence of the way in which numbers of people were employed for weeks beforehand in making preparations for the census. In one province there were complaints that the revenue could not be got in because the people were employed on the census, in another that the land could not be surveyed as usual, because the village officer was employed in the census, and only a few days ago a tea-planter stated that for the first weeks in January he could not get any work out of his clerks on the tea-gardens, because they were all employed on the census. All this interfered with the general business of the country, and cost a quarter of a million, and he hoped, therefore, notwithstanding what statistical-minded gentlemen might say, that India would not be troubled with a census oftener than once in ten years. With regard to the registration of births and deaths, it was stated that in some parts that was very incomplete, and so it was in some cases, but in some parts, notably in Berar, the Central Provinces, and the North-West Provinces, the registration was particularly well done. The census returns and the registrations were tested in this way—to the total for 1881 were added all the births during the succeeding decade, and from that the registered deaths were deducted, and the two results, by the census of 1891 and by the registration figures, came out within one-fifth of a per cent. of each other. According to the calculation from the registration returns there ought to have been 47,680,000 people in the North-West Provinces, and according to the census there were 46,931,000. Sir William Plowden had referred to the great increase in population. It had increased nearly 35,000,000 during the last ten years. Perhaps 4,000,000 were due to the increase of territory, and some might be accounted for by better counting, but there was certainly a clear addition of nearly 30,000,000. Going back two decades further, it would be found that the population had increased 70,000,000 during the last generation. If it went on at the same rate, by the middle of the next century the population of the Indian empire and its feudatories would have reached the enormous total of 500,000,000. Sir William Plowden ex-

pressed the belief that the people in India were, as a mass, better off than they were a generation ago. He adverted specially to Madras, and Mr. Martin Wood expressed the hope that this matter, the condition of the ryots in Madras, would be more thoroughly sifted. It had just recently been very thoroughly sifted, for there arrived by the last mail at the India-office a report by a native gentleman, a Registrar of Assurances in Madras, a very experienced and educated native official, Mr. Srinavasa Aiyengar. He had just completed a report on which he had been at work for two years, on the condition of the Madras Presidency, especially the poor classes. He had not only gathered statistics, but had taken evidence from natives all over the Presidency, and gave chapter and verse for his conclusions. He was of opinion that the population of the Madras Presidency was decidedly much better off on the whole than they were a generation ago, and infinitely better off than they were 150 years ago; yet they were often told that the people of India were very much better off under the old *regime* than under the new. There had been terrible famines during the last 30 years, and it was said that such things were not known before; but Mr. Srinavasa Aiyengar had brought out the fact that in the old times there were terrible famines, and that they caused terrible distress and loss of life. If India had been exempt from famine during the last 10 or 12 years, they could not expect such exemption to continue; but it was not necessary that Britain should take upon herself the guilt and the shame of bringing these famines upon India, for he believed the power of the country and the people to meet famine was much greater than it ever was before. This was the last meeting of the Session, and he was glad they had had so good a paper to conclude a very successful Session. When thanking Mr. Samuel Digby for reading the paper, he would add an expression of the Indian Section's cordial thanks for the energetic and wise efforts by which that gentleman had made the Session so satisfactory and so successful.

Sir GEORGE BIRDWOOD said he rose to move the vote of thanks to Mr. Baines for his most valuable and interesting paper, which he hoped would be supplemented on some future occasion by another from the same writer on the results of the Indian census. Mr. Baines, in the midst of his overwhelming duties in connection with the census, had put himself to the greatest possible trouble and inconvenience in preparing his elaborate paper for the Society, and for this alone, independently of its great intrinsic worth, he deserved their warmest acknowledgments. Beyond this, and recording his hearty concurrence in the compliments paid by the Chairman to Mr. Samuel Digby for the successful manner in which he had discharged his duties during the closing Session as Secretary to the Indian Section of the Society, he would have preferred at this late hour to say no more. But he could not help adding how deeply he resented the attacks that had been made by more than one speaker on the ignorance of the people of India, simply because their traditional culture was of altogether a different type from our own. For his part, nothing gave him more pleasure in listening to the reading of Mr. Baines's paper than the evidence it afforded that the vast masses of the historical populations of India were still, in spite of our Educational Departments, living in the ignorance of Western learning and science which is bliss, in unquestioning good fellowship with their "Gods of the Elder Days." The obstacles thus presented in India to scientific research were often very amusing. In his first medical appointment at Sholapore, it was a part of his duty to record the daily rainfall, a work in which he took the greatest interest, an interest with which his Hindu assistant seemed to show the liveliest sympathy. But gradually a zanthic tint in the gauge, and the uniformity of the daily returns, aroused his suspicions, and on inquiring closely into the matter, he found that his assistant had for weeks been playing the part of Jupiter Pluvius, out of sheer good nature to gratify his (Sir George Birdwood's) youthful enthusiasm. By a singular coincidence when in after years he had to prepare the weekly rain returns for the whole Presidency of Bombay, he found the rainfall for the Esplanade had been vitiated for years by the contributions of a favourite dog to the gauge exposed in the hospital compound of the marine battalion every monsoon.

The vote of thanks having been put by the chairman, was carried unanimously.

Mr. Baines arrived in England on the 1st June, and, having seen a proof of the discussion, has been so good as to send the following note for publication:—

Up to the middle of April, I was still in hopes of being able to leave India in time to read the paper myself; but the revision of the work in one or two provinces was not finished by the latest date which could have landed me in London by the 19th May. As regards the paper itself, I wish to point out that it is statedly about the administration, not the results of the census. I wished to include the latter, and, when first asked for a paper on the Indian census, I hoped to have been able to carry out this intention, as the main tables were already in my hands. Unfortunately, however, there were unforeseen troubles in store, connected with the floating population in Bengal and the North-West Provinces, which entailed alterations throughout the whole series of returns; and it was only in the beginning of May that I was able to finally close the totals for India. Until I had submitted the latter to the supreme Government, I did not consider myself at liberty to publish them, except in a very general form, so that I made no use of them in writing for this Society. It may be interesting, however, to set down a few of the leading features of the census results,

though I must reserve explanations for a future occasion. The population of India, then, is distributed between British territory and feudatory States, giving 221,173,000 to the former, and 66,050,500 to the latter. The Shan States roughly contain 375,000 persons, and Sikkim 20,500, excluded from the above figures, and there are sundry unenumerated tracts in Rajputana, Upper Burma, British Beluchistan, &c., which are estimated to contain about 450,000 inhabitants in addition to those enumerated. The census deals, therefore, with 287,223,000 in round numbers. Dividing them into rural and urban, we find only 27,251,000 of the latter, of whom 6,173,000 live in the large cities of 100,000 and upwards; 3,200,000 in towns of from 50,000 to 100,000 inhabitants; 4,500,000 in those of from 20,000 to 50,000; 5,500,000 in the large market towns (10,000-20,000); and 7,800,000 in towns of less population. If we exclude from the sum the towns not enumerated at last census, it will be found that the whole urban population has increased by about 9⅓ per cent. The rate is higher in the larger towns and those of middle size than in the smaller ones. Bombay heads the list, if we exclude suburbs and adjacent municipal areas, as it shows a population of 821,764; Calcutta city, with its immediate suburbs, returns only 741,144, but taking with it the adjacent towns, forming practically the metropolitan area, the population is 978,370. There is a long drop to Madras, with 452,000, and Hydrabad, with 415,000, including suburbs. In the case of both Bombay and Calcutta the tendency is just the same as in London, namely, to live in the suburbs or adjacent towns, and haunt the city only for business during the day. In Calcutta this tendency is especially strongly indicated in the census returns. In Bombay the most marked feature in the enumeration is the decrease of women, due, greatly, to the improved service of coasting steamers, which allows men to run up and down without transferring their families from their native place. I will now turn to the general variation in population, though this has been treated of already by Sir R. Temple. The return is shown in two sections; first, the nett variation, that is, the increase in provinces and States enumerated in 1881, the result being an addition of 19,294,500 to the former and of 8,526,900 to the latter. In many cases the high rates of increase amongst females, as compared with that of the other sex, is most probably attributable to the greater confidence or intelligence on the part of the householders, so that the actual increase is less than that shown by the figures. On the other hand, the details show a considerable movement in the more sparsely populated but fertile tracts of the Punjab and Central India, and the return to normal prosperity of the famine-stricken tracts of Madras and Mysore. In connection with such movements, however, I may add that the birthplace returns show little actual migration beyond the adjacent districts or States. There are exceptions, of course, as in the case of Assam, Lower Burma, and the flow from South Behar into Calcutta, and from the coast into Bombay; but the total results are that, out of 286,025,000 persons born in India, 275,115,000 were enumerated in the same province as that in which they were born, 9,481,000 in provinces contiguous to it, and only 1,429,000 in other parts of the country. As to immigration from outside, there are only about 732,500 persons returned as born elsewhere than in India; and of these nearly 580,000 belong to territory immediately contiguous to India, and 107,700 to Europe. The additions to the enumerated population which did not come under the census of 1881 comprise mainly Upper Burma, 2,947,000; Lushai, 43,600; and Quettah, 27,270, under the head of British possessions; and Kashmir, 2,543,900 of the States. Thus, the census now under review deals with about 33,386,200 persons more than that of ten years back, of which nearly 28,000,000 are attributable, for the most part, to increase in population, and 5,300,000 to accretion on the register only. The details of the variation have been well analysed in the provincial reviews that have reached me; and the real growth of the population will, ultimately, I trust, be separable from that merely due to greater accuracy in the operations. I will not burden the *Journal* with more figures at present, except to mention, as being a matter of recent interest, that the number of lepers returned is only 126,126, of whom but 30,990 are females. The only tracts in which this information was not returned are Central India and Kashmir, so the data may be taken as fairly general; and as special investigation was made into their accuracy wherever great discrepancy was found when compared with the corresponding return for 1881, I think the results may be taken to be as correct as can be expected from a non-medical enumeration. I will end these remarks by thanking Sir Charles Bernard, and other members of the Society who took part in the discussion, for the hospitable manner in which they received my paper. In connection with Sir William Plowden's remarks on the promptitude with which the population return was published, I must, in justice to him, mention that the corresponding table was issued in 1881, about six months after the census. The greater length of the interval was due mainly to the want of timely notice before the census of the need of urgency. In my case, the main object was to let officials have the return for use before the end of the year, upon which they had to report in April. Copies of the tables and returns of the census will be forwarded for the library as I issue them.

APPLIED ART SECTION.

Mr. De Morgan's paper on "Lustre Ware," read on Tuesday, May 31st, and the report of the discussion, will be printed in an early number of the *Journal*.

Miscellaneous.

NIAGARA AND ELECTRICITY.

Professor George Forbes, F.R.S., has communicated to *The Times* a letter on the extensive works for the utilisation of the Niagara Falls in the production of electricity, from which the following extract has been made. Prof. Forbes, after referring to his dreams of eight years ago, when he stood on the southern edge of the American Fall, writes:—

"And now, eight years after, I see that the preparations are almost complete for the utilisation of 100,000 horse-power, and part of this power will certainly be used long before the close of the year.

"Few people in England who have heard of this engineering feat are aware of how far it has been advanced. More than a mile above the falls a canal has been cut 1,500 feet long, at right angles to the river. A vertical shaft, 140 feet deep, is being sunk, and from a lower level a tunnel, 28 feet high, and 18 feet wide, and 6,700 feet long, has been carried at a slope of 7 per 1,000, to issue at the foot of the cliffs below the falls, just under the suspension-bridge. This work is all nearly completed. The lining of the tunnel with four courses of bricks is going on at the rate of 100,000 a day, and this rate is about to be increased. The turbines are in hand, Part of the power is to be used in factories now being built directly over shafts, and we are now preparing for the electrical transmission of power. In a year's time it is probable that the city of Niagara Falls will be lighted by this power, and the street electric railways worked by it. Factories are being erected on the vast extent of land owned by the company which has a perpetual right to use this power over five miles of river frontage from a little above the falls upwards. Already thirty acres of land have been reclaimed by the company from the river, and the river is about to be deepened in front of their wharves. A railway, five miles long, all passing through the company's land, is in hand to connect the three lines of railway with the principal factories on the company's property. This will eventually be worked by an electric locomotive. Streets have been laid out and a part has been laid aside for operatives' cottages. All this I have seen, and I recognise the foundation of an important manufacturing centre. Franchises have been obtained from owners of property for a second tunnel under the city of Niagara Falls. All this has been done, and at a surprising small cost, by the energy, caution, and foresight of the directors of the company, of which Mr. Adams is the president, Mr. Wickes and Mr. Stetson vice-presidents, and Mr. Rankine (a cousin of Professor Macquorne Rankine) the secretary. In 1890, they appointed a Commission of leading scientific men in Europe and America, presided over by Lord Kelvin. These Commissioners considered all the proposals submitted, and since then the company's engineers have dealt with the hydraulic problems. The Board of Engineers includes the names of such men as Professor Colman Sellers, Mr. Herschel, and Colonel Turrentini, of Geneva. The electric part of the work is now to be carried out. In 1890, when preparing plans to lay before the Commission, I proposed to employ alternating currents, using as motors either the alternating dynamo or the multiphase motor, which has since attracted so much attention at Frankfort last year. This was an innovation on previous practice, and it is worthy of record that the Commission were unanimous (with one exception) in desiring to pass a resolution, saying that alternating currents were not available for the purpose. Already opinion has changed, and the subsequent progress has so completely borne out the views expressed in 1890 that we are going to adopt this method.

"It may be that what I have already written may convince many of the enormous character of this undertaking. But the importance of the company's transactions has been only half told. They have lately acquired from Canada the exclusive right to use land in the Victoria-park for the same purpose for 100 years. The river above the Horseshoe Fall on the Canadian side has a branch going round Cedar Island. The power-house can be built here. Enough water can be brought through the branch to utilise 250,000 horse-power, and the tunnel from the bottom of the shaft to the very base of the fall will be only about 800 feet long. This franchise is a most valuable addition to the powers possessed by the company on the other side.

"Many visitors to the Chicago Exposition next year will stop to see the progress of this gigantic undertaking, and they will not be disappointed, and it is a matter for congratulation that, so far as the present intentions of the company go, the beauty of the falls will not be affected nor the volume of water perceptibly diminished."

PATENT-OFFICE.

The ninth report of the Comptroller-General of Patents for the year 1891 has just been issued. It shows the usual growth in the number of applications for patents, which has now reached 22,888, or 1,581 above the number of 1890. The total number of applications for the registration of trade marks was 10,787, as compared with 10,258 applications in the previous year. The revenue of the office is £203,520, made up as follows:—Patent Fees, £181,777 4s. 8d.; Designs Fees, £4,565 2s.; Trade Marks Fees, £11,034 19s. 9d.; Sale of Publications, £6,142 13s. 7d. Of this amount £103,180 was expended, leaving a surplus for the year of £100,339.

The chief items of expenditure are:—£54,267 for

salaries; cost of printing and paper, £16,600; and new works (including purchase of premises), £21,703.

The number of readers at the Patent-office Library during the year amounted to 98,477.

The report also gives information as to the other departments of work of the Patent-office, lists of the places to which grants of the specifications are made. and a copy of the "Patents, Trade Marks, and Rules" now in force.

A NEW USE FOR BAMBOO.

A new application of the stems of the larger-growing species of bamboo has recently been adopted in China for the manufacture of small trays and ornamental articles for export to Europe. It is known in China as bamboo sheeting, and it is said to be carried on at present only to a limited extent at Wenchow, where, notwithstanding that it is quite a new trade, about ten firms are now engaged in it. The process adopted is as follows:—A length of bamboo is cut off, and then pared with an axe till it is of the thickness required. It is next planed with a spokeshave, and the thin cylinder so obtained is slit up, so that, on being opened out, it forms a sheet. A number of these cylinders, placed one inside the other, are immersed in boiling water for a few minutes, to render them flexible, and they are then unrolled and flattened out, by being subjected to pressure under heavy stones. These sheets are sometimes used for making fretwork and carved screens, fans, &c.; and the small, pale, straw-coloured pin-trays, for toilet tables, which appeared in the London shops last season, are apparently made from this specially prepared bamboo. It seems to adapt itself extremely well for moulding into many forms, and might be made available in this country for various kinds of veneering. The bamboo now appears to be the *Dendrocalamus latiflorus*, and specimens of the sheeting, and articles made from it, may be seen in Museum No. 2 of the Royal Gardens, Kew.

Correspondence.

MUD BUILDING.

Mr. William Simpson always brings together on any subject he deals with, a mass of valuable and interesting matter. The one he brought before the Society is very wide in its influence, and invites some notes.

He might have broadly laid down that what he generally terms mud building extends over the eastern world and the western world, because it belongs to that epoch when the same culture and civilisation prevailed in the two hemispheres. But in America, as he says, there is a community of construction between the ancient monuments of Peru, and modern buildings reaching into California. The Spaniards did not really introduce this class of construction, for they found it in America, but they naturally kept up what they had used at home and inherited from antiquity.

Although in this connection Mr. Simpson names *adobe*, he does not name *tapia*, though he has described walling made between frames. If a material is not applied for a dwelling, it will be found in fencing, and walls and fences of *tapia* contribute as much to the development of a country as dwellings of *adobe*. Indeed, the dwelling may be of timber or stone, although the other materials are largely used.

Mr. Simpson has not set it out clearly that the adoption of building materials is governed by soil and climate, and by earthquakes. If trees are at hand, they are used, or they may be floated down by water. In a grass country, fences are made of sods, as cabins lately were in Ireland. The presence of clay and of pebbles largely governs the form of *tapia* and cobwalling, so also of lime. Small stones come in well for cobwalling.

When stones are handy, an acropolis was made, and that in Cyclopean style, without cement, as fences are now made in this country. Mr. Simpson is right that the walls of stone fortifications were surmonnted with mud structures, and, he might have added, wood. When the fortress was simply to secure cattle from marauding bands, a mud or earth wall was enough. Such were some of the Norman castles in this country, and nothing more.

The variety of the applications is very great. In many countries, as in parts of England and America still, timber is preferred, because it is held to be warmer in winter and cooler in summer. Timber is preferred in earthquake countries to mud walling and vaulting, and even to stone, although stone is sometimes relied upon to withstand shocks. As Sir Charles Wilson gives testimony, abundant examples were to be found in Asia Minor of earth construction.

With regard to cobwalling, much attention was given to it here, about 40 years ago; and to Mr. Simpson's list (p. 704) there may be added, I think, the "Civil Engineer and Architect's Journal." This material has not been despised here. It has, however, developed into concrete, and in that form has been largely used and acknowledged as an engineering expedient. In London, too, there are houses and walls built of cobwalling, under the name of concrete.

To the description of mud bricks in Egypt from M. Maspero (p. 677), I should be inclined to add that I have seen bricks prepared by simply cutting the surface mud into squares after the inundation. This appeared to me to be the primitive form, as under the heat they scaled off in flat squares.

Mr. Simpson is quite justified in affirming that earthy materials have influenced the forms of archi-

tecture, but that mud is the beginning of all would be a doubtful proposition, for the reason that local influences have their respective actions. One natural artificer who may have given an example is the beaver, a builder and engineer.

HYDE CLARKE.

32, St. George's-square, S.W.,
6th June, 1892.

Obituary.

SIR JAMES BRUNLEES.—Sir James Brunlees, the eminent engineer, who had been a member of the Society of Arts since 1858, died at Argyle-lodge, Wimbledon, on Thursday, 2nd inst. He was born at Kelso, N.B., January 5, 1816, and was educated at Edinburgh University. In 1838 he became an assistant engineer to Mr. Alexander Adie on the Bolton and Preston Railway. Subsequently, under Sir John Hawkshaw, he was occupied with the works of the Lancashire and Yorkshire Railway. He next constructed the Londonderry and Coleraine Railway, and then the works of the Ulverston and Lancaster Railway. Since that time his principal works were the Solway Junction Railway, the Clifton Extension Railway, the Mersey Tunnel Railway, and the Avonmouth, King's Lynn, and Whitehaven Docks, the San Paulo Railway, the Minas and Rio Railway, the Porto Alegre Railway, and the Central Uruguay and Bolivar Railway. He was knighted in 1886, and received from the late Emperor of Brazil the decoration of the Order of the Rose. Sir J. Brunlees was president of the Institution of Civil Engineers in 1882-83, and a member of the Council of the Society of Arts in 1876-77.

General Notes.

SOUTH KENSINGTON MUSEUM.—The gallery assigned to the large collection of wrought iron work, which has for some time been closed for re-arrangement, was open to the public on Whit-Monday, 6th inst. The larger grilles and screens, including the gates from Hampton-court, are now placed in the arched spaces on either side, while the lanterns, cressets, signs, &c., are suspended along the gallery, smaller objects being shown in sloping glass cases. Among these last is a series of rush-candle holders, tobacco tongs, and other domestic implements used in England, chiefly in the 18th century, collected and lent by Lady Dorothy Nevill. Examples of the locksmith's art, English, French, and German, are numerous, including some chiselled steel locks and keys from old French buildings, but produced by "Johannes Wilkes de Birmingham" in the 17th century. Some of the more famous specimens of mediæval work in English cathedrals have been reproduced in *fac-simile*.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 13 ... Engineers, Westminster Town-hall, S.W., 7½ p.m. Mr. Albert Wollheim, "Foreign Sewage Precipitation Works."
Chemical Industry (London Section), Burlington-house, W., 8 p.m. 1. Prof. V. B. Lewes, "Oil Gas." 2. Mr. Watson Smith, "The Soluble Bituminous Constituents of certain Japanese Coals."
British Architects, 9, Conduit-street, W., 8 p.m.

TUESDAY, JUNE 14...Gas Institute, 28, Great George-street, S.W., 8 p.m. General Meeting. President's Address, reading of Papers, and Discussion.
Medical and Chirurgical, 20, Hanover-square, W., 8½ p.m.
Zoological, 3, Hanover-square, W., 8½ p.m. 1. Mr. F. E. Beddard, "The Brain and Muscular Anatomy of *Aulacodus*." 2. Mr. G. W. Butler, "The Subdivision of the Body Cavity in Snakes." 3. Mr. J. W. Gregory, "The British Paleogene Bryozoa."
Colonial Institute, Whitehall Rooms, Northumberland-avenue, W.C., 8 p.m. Lord Brassey, "Our West Indian Colonies; their Resources and Means of Defence."

WEDNESDAY, JUNE 15...Japan Society (at the HOUSE OF THE SOCIETY OF ARTS), 8½ p.m. Mr. Ernest Hart, "Some Japanese Industrial Art Workers."
Meteorological, 25, Great George-street, S.W., 7 p.m. 1. Mr. F. C. Bayard, "English Climatology, 1881-1890." 2. Mr. William Ellis, "The Mean Temperature of the Air on each day of the year at the Royal Observatory, Greenwich, on the average of the 50 years, 1841 to 1890."
Microscopical, 20, Hanover-square, W., 8 p.m.
Gas Institute, 25, Great George-street, S.W., 10 a.m. Commemorative "Murdoch" Lecture, by Prof. Vivian B. Lewes, "A Century of Work on the Development of Light from Coal Gas." Reading of papers and discussions continued.

THURSDAY, JUNE 16...Royal, Burlington-house, W., 4½ p.m.
Antiquaries, Burlington-house, W., 8½ p.m.
Linnean, Burlington-house, W., 8 p.m. 1. Prof. J. R. Henderson, "Contributions to Indian Carcinology." 2. H. B. Guppy, "The Thames as an Agent in Plant Disposal." 3. Miss M. F. Ewart, "Some Abnormal Development of the Flowers of Cypripedium." 4. Mr. R. I. Pocock, "Supplementary Notes on the Fauna of the Mergin Archipelago." 5. Lantern Demonstration.
Chemical, Burlington-house, W., 8 p.m. 1. Dr. H. E. Armstrong, "Contributions to an International System of Nomenclature: the Nomenclature of Cycloids." 2. Dr. N. Collie, "The Production of Pyridine Derivatives from the Lactone of Triacetic Acid."
Society for the Encouragement of Fine Arts, 9, Conduit-street, W. Morning meeting.
Gas Institute, 25, Great George-street, S.W., 10 a.m. Reading of papers and discussions continued.
Historical, 11, Chandos-street, W., 8½ p.m.
Numismatic, 22, Albemarle-street, W., 7 p.m. Annual Meeting.

FRIDAY, JUNE 17...Quekett Microscopical Club, 20, Hanover-square, W.C., 8 p.m.
Physical, Science Schools, South Kensington, S.W., 5 p.m.

The Telegraphic Address of the Society of Arts and of the Royal Commission for the Chicago Exhibition, is "Praxiteles, London."

Journal of the Society of Arts.

No. 2,065. Vol. XL.

FRIDAY, JUNE 17, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Thirty-Eighth Annual General Meeting, for the purpose of receiving the Council's Report and the Treasurers' statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new members, will be held, in accordance with the Bye-laws, on Wednesday, the 29th June, at 4 p.m.

(By order of the Council),

Henry Trueman Wood,
Secretary.

CONVERSAZIONE.

The Society's *conversazione* will take place at the South Kensington Museum (by permission of the Lords of the Committee of Council on Education) on Wednesday, 29th June.

The reception by the Attorney-General (Sir Richard Webster, M.P.), Chairman, and the Members of the Council of the Society will be held from 9 to 10 p.m.

Promenade Concerts will be given by the Band of Royal Engineers in the North Court, and by the Band of the Scots Guards (weather permitting), in the Quadrangle of the Museum.

A Vocal and Instrumental Concert by the Meistersingers and Meistersingers' Orchestra will be given in the Lecture Theatre under the direction of Mr. Norfolk Megone. The first part of the concert will commence at 9.30.

Light refreshments (tea, coffee, ices, claret cup, &c.) will be supplied at the usual Refreshment Buffets in the Central Corridor of the Museum.

Programmes of the musical and other arrangements will be distributed on the evening.

Each member is entitled to a card for himself, which will not be transferable, and a card for a lady. The conditions under which the use of the Museum has been granted by the Science and Art Department do not permit the sale of tickets; Members will therefore not be able to purchase additional tickets for their friends, as in recent years.

The tickets are now in course of issue to the members.

Chicago Exhibition, 1893.

OFFICES OF THE BRITISH SECTION.

A view of the building now in course of erection on the shore of Lake Michigan, which is intended to serve as offices and headquarters of the British Section, is given as a Supplement to the present number of the *Journal.* The design is furnished by Colonel Edis, Hon. Architect to the Commission.

The building will be generally characteristic of the best type of English half timber houses of the 16th century, of which there are so many good examples still extant. It is proposed to use terra-cotta somewhat largely in the lower storey, with red brick facing and mullioned windows, so that the building may be a typical example of an old English house. The upper portion will be of half timber construction, with overhanging and projecting gables. As the building will be seen from all points, each façade has had to be treated architecturally. The plan forms three sides of a quadrangle with the open side next the lake, enclosed by a raised terrace with balustrade. The centre on the front or inland side will be recessed, with steps leading from both sides up the covered portico, which will open into a large central hall; off this will be, on one side, large library and reception rooms, and on the other, the secretary's office and the other rooms required for the work of the Commission. On the first floor will be a large suite of rooms and offices. It is intended to fit up all the principal rooms with wall panelling and elaborate ceilings, after the manner of some of the best English country houses. The whole of the internal fittings and furniture will be executed from Colonel Edis's designs by Messrs. Johnstone, Norman, and Co., of New Bond-street. The foundations of the building have already been commenced, and the superstructure will be pushed forward with all speed,

so as to be finished complete for the opening in May next.

Besides the necessary offices the house will contain some large rooms suitable for meetings of juries, receptions, &c., and the Commission hope that the accommodation thus provided may be found useful, not only for their own purposes, but for those of the various Colonial Commissions.

MEETINGS OF THE ROYAL COMMISSION.

A meeting was held on Friday, 10th June. Present:—The Attorney-General, M.P., Q.C., in the chair; Sir Frederick Abel, K.C.B., D.C.L., D.Sc., F.R.S., Major-General Sir Owen Tudor Burne, K.C.S.I., C.I.E., Michael Carteighe, B. Francis Cobb, Sir Philip Cunliffe-Owen, K.C.B., K.C.M.G., C.I.E., Prof. James Dewar, M.A., F.R.S., Major-General J. F. D. Donnelly, C.B., James Dredge, Sir Douglas Galton, K.C.B., D.C.L., F.R.S., Thomas Hawksley, F.R.S., Charles Malcolm Kennedy, C.B., William Henry Preece, F.R.S., Sir Robert Rawlinson, K.C.B., Professor William Chandler Roberts-Austen, C.B., F.R.S., with Sir Henry Trueman Wood, M.A., Secretary. A meeting was held on Tuesday, 14th June. Present:—The Attorney-General, M.P., Q.C., in the chair; Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., Michael Carteighe, B. Francis Cobb, Sir Philip Cunliffe-Owen, K.C.B., K.C.M.G., C.I.E., Professor James Dewar, M.A., F.R.S., Sir Henry Doulton, James Dredge, Francis Elgar, LL.D., Sir Douglas Galton, K.C.B., D.C.L., F.R.S., Thomas Hawksley, F.R.S., Alexander B. W. Kennedy, F.R.S., Charles Malcolm Kennedy, C.B., George Matthey, F.R.S., Professor William Chandler Roberts-Austen, C.B., F.R.S., Sir Owen Robert, M.A., F.S.A., with Sir Henry Trueman Wood, M.A. Secretary.

Proceedings of the Society.

FOREIGN & COLONIAL SECTION.

Tuesday, May 24, 1892; the Hon. JAMES MUNRO in the chair.

The paper read was—

THE EXTENSION OF COLONIAL TRADE.

By COLONEL HOWARD VINCENT, C.B., M.P.

The Council of the Society of Arts has been so good as to invite me to deliver a brief address upon the extension of colonial trade. I gladly respond, and the more so as within the past month the representatives of the people in the Dominion of Canada have, by a considerable majority, given a new aspect—a fresh possibility thereto.

First though, Mr. Munro, let me, as one deeply attached to the cause of colonial development, welcome you to this first, or at least one of the first, public acts of your career as Agent-General of Victoria. I esteem myself greatly honoured by your chairmanship this evening. The mother land, I am certain, is glad to see in her metropolis those distinguished sons who have upheld and carried forward the British banner in distant seas.

We have heard something of late of depression in Australia, of financial difficulty succeeding over-speculation. But you will be able to tell this gathering that with such unparalleled resources, with such boundless territory, with the riches of the surface competing with mineral wealth, passing depression may, for the hour, steady, but cannot check, the certain prosperity. The Premier of New South Wales, will, when he arrives, be able to corroborate you. Those of us who have seen with our own eyes will be friendly witnesses.

"Advance Australia" is your motto, but more than your motto. It is the command of heaven, the decree of the Creator of the universe.

Colonial Trade! Are we to consider colonial trade in its aspect of to-day alone, to weigh it only by pounds and shillings, by hundred weights and quarters of present measure, to weigh it only by our own comparative neglect, or rather want of encouragement? Or are we to weigh it by what it might have been under more favoured conditions, what it may be in the future if only common sense prevail, and the duty is recognised of developing rather our common Empire instead of wasting our millions upon foreign soils.

We can look at it in the double aspect. Some there are, I know, whose horizon is bounded by a Board of Trade return, who say that whereas the foreigner holds four-fifths of the world, and the British Empire occupies but one-fifth, and that the foreign trade is there-

fore of bigger volume than the colonial trade, it is of the former we must be mindful, even to the extent of letting the latter go by the board.

We need not fear to face the facts. What materials have we to guide us? The full data are always and necessarily eighteen or twenty months in arrear, and we all know that a much shorter time is sufficient to completely change the aspect of commerce in these days when, as Lord Salisbury put it recently, every foreign nation is engaged "in industrial warfare with protective legislation as its weapon, and its prize the markets of various countries." And who is the principal adversary? We English. Treaties and politics have been winding band after band round our limbs, and reducing us to utter helplessness. The highest political authority in the land corroborates this. Let us examine the Statement of Trade for 1890, the Statistical Abstract for 1890, the Trade and Navigation returns for 1891, and the Customs Record of the past four months.

It is true that in 1890 colonial trade with the United Kingdom amounted only to £190,000,000, whereas that between foreign countries and the United Kingdom amounted to £558,000,000. But what a different character the totals represent. In the one case we have practically complete equality between goods bought and goods sold. But in the case of the foreigner there is a balance against us of £90,000,000. In 1891 this adverse balance is increased to £126,000,000, and in the present year it bids fair to be very considerably higher. Four months' trading in 1892 show a decline of British export amounting to nearly £7,000,000, and an increase in imports of close on £4,000,000. Which trade exhibits the greatest vitality, the foreign or the colonial trade?

In 1855, we find each head of the population of the United Kingdom is buying of the foreigner to the value of £3 19s. 1d., and is selling to the foreigner £3 3s. 2d. worth of British produce. But in 1890 each head in Great Britain and Ireland bought £8 13s. 4d. worth of foreign goods, and sold but £6 4s. 6d. worth of British goods. On the other hand, the imports from the colonies have risen, in these thirty-five years, from £33,500,000 to £96,000,000; from £1 6s. 1d. per head to £2 11s. 3d., and the purchases by the colonies from £28,750,000 to £94,000,000, or from £1 0s. 9d. per head in 1855 to £2 10s. 9d. per head in 1890—or only 6d. per head less sales than purchases, instead of £2 8s. 10d. less per head, as in the case of the foreigner.

It seems absolutely clear, under such circumstances, that to the individual producer in the mother country, the colonial trade is infinitely more profitable, more advantageous, fairer in its operations than foreign trade. Of course we are all well aware of the fact that every Australasian buys nearly £6 worth of British goods, every South African brother £4 11s. worth, and every Canadian £1 9s. worth, compared to 8s. 3d. of the German, the 8s. 8d. of the Frenchman, or the 8d. of the Austrian. This is a matter of much importance to the home population.

Let us not be content, however, with looking at totals only. Let us go into details, and then we see most clearly that the argument gains greatly in force. While a considerable proportion—much more than a third—of our exports to foreign countries—a total of some £66,000,000—are composed of raw material, machines, and implements, and partially-manufactured goods, to facilitate the competition of the foreigner with us in his own and foreign markets, as well as on our own ground, upon unequal terms, that is free of the taxation the home produced article has to bear—the major portion of the colonial purchase is of goods manufactured by British labour. This is well illustrated by the following extract from the Report of the British Chamber of Commerce in Paris for last year:—

"More than half the imports from England consisted of natural products, of which nearly a third was Australian and Cape wool, while the greater part of the exports from France to England were manufactures, the produce of French labour. The value of the French manufactures sent to England was in fact within £400,000 of the amount of all the English exports and re-exports to France—food, raw materials, and manufactures combined."

Now as to the products of home labour taken by the colonies.

Of £62,000,000 worth of cotton manufactures exported, £27,500,000 worth go to the fifth of the world under the British flag. Of £24,000,000 worth of iron and steel manufactures exported, £9,000,000 worth go to our fifth of the earth. Of £2,750,000 worth of hardware and cutlery sold over the sea, £1,165,000 worth goes to British possessions.

Our fellow subjects take five times as much British apparel, haberdashery, and millinery as every foreign nation put together; three times the quantity of leather goods, a larger quantity of glass manufactures, and an equal

amount of hats, umbrellas, stationery, and steel rails. In short, while foreign flags combined only take £116,000,000 worth of British finished manufactures, the colonies and dependencies of England take £73,000,000 worth. Nothing can show more clearly the value to each individual in this country of the empire.

Then, as to the import trade, it has been admirably analysed by Mr. James Edgcome. There is an import of £88,500,000 worth of natural food products. Of these foreign countries send us practically two-thirds, and the Empire one-third, and £8,000,000 are re-exported, leaving a balance for consumption of £80,000,000 worth. There is an import of £78,000,000 worth of manufactured food products. Of these foreign countries send us all but £7,000,000 worth; £5,500,000 worth are re-exported, so that the net import of food amounts to £153,000,000. There is a large balance, though, to account for. Thereof £159,000,000 consists of raw material, and to it the colonies contribute over £54,000,000; £37,000,000 worth goes to be made up abroad, and a large proportion re-appears. But in what state? Worked up by foreigners. Close upon £57,000,000 worth of fully manufactured goods they send us free of all toll, and £50,000,000 worth remain for use in the United Kingdom. In addition there is an import of £24,000,000 worth more of foreign partly manufactured goods, making £76,000,000 of manufactured goods brought into this country from abroad, while the importation of colonial manufactured goods amounts to only £10,000,000, of which at least a third are re-exported.

It will thus, I hope, be seen that not only do the colonies buy far more of the goods made by English labour than foreign nations in proportion to their extent and population, but that which they send us in exchange competes less with our wage yielding enterprises, but rather affords occasion for remunerative employment.

The returns of the first four months of 1892 illustrate even more eloquently the growing extension of colonial trade. They show not only that the shrinkage of export, owing to recent financial depression and other causes, is much less acute as regards British possessions than with respect to foreign countries. The latter have taken upwards of £4,000,000 worth less of British goods than in the same four months of 1890, while the Colonies are only £1,000,000 in arrear. Our kith and kin have bought this year £20,100,000 worth of British manufactures, while all the rest of the world has taken but a gross total of £38,000,000, whereof about £10,000,000 was in respect of raw material, mill work, and machinery—leading to increased foreign competition with our manufactures. The real proportionate value, therefore, of British possessions to the English, Scotch, or Irish artisan, as compared with foreign countries, and illustrated by this year's trading, is as 5 is to 7—and this in spite of a policy of timorous drift.

The past four months show clearly that, as a market, without consideration of the character of the purchases, India is worth as much to the British artisan as Germany, Holland, and Belgium combined; as much as the United States, Russia, and Northern Europe combined; that Australasia is worth as much to the English mechanic as the whole of the Republics of South America; that Canada, the West Indies, and South Africa are worth as much as France, as much as Turkey, Egypt, China, and Japan put together, and more than the whole of Southern Europe.

It seems absurd, under such circumstances, to ask, Is the colonial trade worth cultivating? I put the proposition, however, in this interrogative form that the debate to be presently raised may turn upon it. For myself, as a representative of an industrial community, I do not hesitate to say that it not only presents greater commercial opportunities, but carries with it political considerations of the most vital character. There are honourable gentlemen present who will be able to offer cogent arguments for consideration upon this head. They will doubtless also call attention to the important fact that the sales of the colonies to the mother country, notwithstanding the diminished exports, show an increase for the past four months of over 16 per cent., and point undoubtedly to these islands as affording to colonial producers the best and most certain market—a market after a time they could easily supply with all the corn it demands. It is not necessary, therefore, for me unduly to dwell thereon. But it is important to consider if it will be best to leave the extension of colonial trade entirely to its natural course, or to assist it by such means as we can.

What is our position? In the first place, England is the only colonial power which does not place the commercial relations between the mother country and the colonies on a different footing to the commercial relations with foreign countries. We may be the greatest

colonial power of the day, but in the acquisition of colonial possessions we have only followed in the footsteps of Greece and of Rome, of Spain and the Netherlands. Their aim was the extension of commerce; ours was the extension of commerce. The same motive influences at this hour both France and Germany; but alone among the nations do we treat the colonies, acquired entirely by the three great qualities of the British race—courage, adventure, and enterprise—on absolutely the same footing as foreign countries. We give no advantage, we gain no advantage, over the foreigner. Is this common sense? "Does the parent build his house, establish a business, to house the stranger, to enrich the rival." Emphatically not. There is no difference whatever in the relationship between a mother country and her colonies, and that of a father to his sons.

Now what is the result of this extraordinary policy into which England has drifted—for reasons the Prime Minister has declared "we have been unable from the papers in our possession to ascertain."

I have endeavoured to set before you the importance to the mother country of its colonial trade. But let it not be assumed that because our colonial trade exhibits greater buoyancy than foreign trade, that foreign nations have been slow to take advantage of the insane limitation the anti-colonial policy of a former generation imposed on their fiscal liberty by the treaties of 1862 and 1868, which bound them to place the United Kingdom and foreign nations or one and the same footing. No, they have profited, are profiting to the fullest extent, and in the past twenty years the sales of foreign countries to British possessions have increased over 84 per cent., while the sales of the Empire to the Empire have only increased 42 per cent. or one-half the former. That is a serious matter, and although it is true that the Inter-British trade is greatly in excess of the trade between foreign countries and British possessions, the latter are gaining fast and the former receding. The last few months have seen the British West Indies compelled to give to the United States its own terms, expressed in the haughty language of superior bargaining power, although they will involve, if not discriminative, at least an increase in the duties upon British manufactures.

It is not likely that foreign powers will come to England to deprive them of their boon of commercial rank *pari passu* on British soil with Britons, and it is nothing less than pitiable to hear a British Minister declare that he can do nothing because Belgium and Germany have not volunteered to surrender the cake.

Let us look at recent events in Canada and Australia.

In the Dominion we find that practically within the past six months two pregnant messages of State have been sent to the Mother Country. The first at the end of September from the Senate and House of Commons of Canada. Relieve us, says the address to the Imperial Government, of these treaty shackles your illustrious chief declares to be so "unfortunate" and so "unlucky," your Minister of Commerce to be "relics of a past generation." Give us the power to put a lighter duty on British than on German goods.

Again, within the past four weeks, the Dominion House of Commons speaks with a voice both loud and strong.

It needed not the eloquence of Mr. Alexander McNeill, nor yet the support of M. Desjardins, that leading representative of our loyal French Canadian fellow subjects to commend this resolution to the People's House:—"That if and when the Parliament of Great Britain and Ireland admits Canadian—that is, colonial—products to the markets of the United Kingdom upon more favourable terms than it accords to the products of foreign countries, the Parliament of Canada will be prepared to accord corresponding advantages by a substantial reduction in the duties it imposes upon British manufactured goods."

That motion was carried by a great majority, and even the most impassioned of the leaders of the policy of unrestricted reciprocity and discrimination against the Mother Country had naught to urge in opposition. More than the mere figures indicated, this I say, that the people were behind that vote. I have warrant for this statement, in that in every commercial centre in Canada I have heard with my own ears the people's voice rise in support to the public platform. I have warrant for this statement, in that, eight months ago, after the death of Sir John McDonald, the illustrious author of the phrase, "A British subject I was born, a British subject I will die," the Dominion Government was upon the balance; upwards of 100 seats were being challenged or petitioned, and the majority was slender. At every bye-election the policy of trade with the mother country or with the United States was the issue, and nearly every

bye-election has added to the forces of the Government.

Why is this? Because although there are not wanting either public men or public prints who, from divers motives, are continually calling attention to the 60,000,000 of people to the south of the Canadian frontier, the loyal majority know full well, as was said in the Ottawa Chamber by Mr. McNeill:—

"Our Empress Queen is mistress of the waterways of the world. Ours are by far the greatest wheat areas in the world; ours are overwhelmingly the greatest wool areas and markets. Our empire could grow more cotton than all the cotton produce of the United States. Ours are the greatest diamond and ruby fields in the world. We are to-day first in the production of tea and of the finest coffee. In coal, iron, copper, and nickel we hold our own with all mankind. We have the greatest timber forests in the world. In sugar growing we hold a good and could hold a better place. In tobacco we come third. Every variety of climate, every variety of soil, everything that mankind can possibly require we possess in our own empire. With six times the population of the United States, with four times that of All the Russias, with that of the whole of Europe, we British subjects are not absolutely and utterly mendicant. It is not absolutely necessary that we should go cringing and whining to the back door of any foreign power to beg a little of their trade for charity. We are quite ready to trade with them, but we will trade with them on fair terms if you please. We are prepared to treat upon fair terms, but only upon fair terms, and in Admiral Blake's words, 'We are not going to be fooled by foreigners.'"

Time was, and very recently, when Australian Ministers complained that their utterances were insufficiently heard and regarded in the mother country. The complaint is likely now to be that too great importance is attached to casual observations and electoral sayings. I will not accentuate this, but simply recall the general tenour of some of the recent arguments in favour of Australsian Federation—a commercial federation on the model of that of the United States, continental free trade and high protection against the mother country and all the world.

There can be little doubt that discrimination in Canada in favour of the United States, in Australasia of commercial hostility to the mother country, must undermine the integrity of the Empire, for if it be true, as it undoubtedly is, that trade follows the flag, it is even more true that political union hangs largely upon community of commerce. There is high authority for this.

Mr. Froude has declared, "It is as sure as the multiplication table that if we do not offer Canada such a union the Americans will, and the Canadian dominion will be lost to us."

Lord Rosebery goes even further. He has said:—

"It is, as I believe, absolutely impossible for you to maintain in the long run your present loose and indefinite relations to your colonies, and preserve those colonies as part of the Empire. It is not merely commercial interests that are involved, it is a narrowing down of this country to its European possessions. Do not flatter yourselves that, if Canada and Australia were to leave you, you would retain your smaller colonies. The West Indies would go with Canada, Australia would take in Australasia, as to the Cape, I think you might make up your minds for the secession of the Cape under circumstances such as those; well, if you wish to remain alone in the world, with Ireland, you can do so."

Everything points, therefore, I submit, to the absolute necessity of doing all that possibly can be done to bring about the extension of colonial trade. I hesitate to mention the subject of foreign tariffs. But it is impossible to disregard them in considering this subject. No man can ignore the fact that the signs of the times are entirely in favour not only of the maintenance of the duties against British trade, but of their increase to a prohibitory rate on the European continent, as already in the United States and France. It is impossible for men to apply the same reasoning to their actions under such circumstances as they would if there was the faintest indication on any part of the earth to extend to Great Britain the treatment she has meted out here, to her nationals and foreigners alike, for the last fifty years. There is, in Great Britain, grave labour trouble close at hand, and it arises from what? From the fact that the pressure for existence has become so severe, that three men are seeking to do the work of one man, and subdivide his earnings. Nothing can be more certain than that neither the possession of parliamentary votes, nor trade unionism, nor the power of combination and of strikes, render the working man master of the situation, so long as the door is left wide open to bring in the product of the labour of other men, and sell it at a much lower price. This was stated categorically the other day by Lord Salisbury to the deputation upon the Eight Hours Question. I recall the words:— "The temptation to a capitalist to take his factory inside a tariff wall, instead of remain-

ing outside, is enormous. If he goes inside the tariff wall, that is to say, to the United States, or to Spain, or to France, he will enjoy entire freedom from the taxation which those countries impose upon goods, while the markets of England will be open to him as before."

Under circumstances such as these it is wholly Utopian to suppose that we are not within measurable distance of an entire economic change—of the adhesion of the governing democracy of England to the governing principle of the democracy of the world—namely, self-protection. It is therefore that I venture to urge on this learned society that upon this the seventy-third birthday of the most illustrious sovereign that has ever adorned the throne of an empire, on the fête day of Queen Victoria in the fifty-fifth year of Her Majesty's most glorious reign, it cannot do better than put forward its influence towards the extension of colonial trade, and aye. towards the commercial union of the British Empire. It has the highest authority for this—that of the Prime Minister :—

"We know that every bit of the world's surface which is not under the British Flag, is a country which may be, and probably will be, closed to us by a hostile tariff. It is to the trade that is carried on within the Empire of the Queen that we look for the vital force of the commerce of this country."

All the world now knows what additional emphasis this declaration received last Wednesday in the address of Lord Salisbury to the people of Sussex and of England :—

"We live in an age of war of tariffs. Every nation is trying how it can, by agreement with its neighbours, get the greatest possible protection for its own industries, and get at the same time the greatest possible access to the markets of its neighbours. This kind of negotiation is continually going on. It has been going on the last year and a half with great activity. I want to point out to you what I observe. Nobody cares two straws about getting the commercial favour of Great Britain. . . . . We begin by saying, 'We will levy no duties on anybody, and we declare that it would be contrary and disloyal to the glorious and sacred doctrine of free trade to levy any duty on anybody for the sake of what we can get by it.' It may be noble, but it is not business."

Nor is the Chancellor of the Exchequer behindhand.

"I must enter my protest [he has told the Commons of England] against an extreme application of the view that under no circumstances could we make fiscal arrangements with the colonies, without injuring other portions of our trade. If we find we could make the whole Empire one as regards customs, surely we have the same right of Zollverein Union with our colonies as Germany has with Bavaria, or the United States among themselves. I claim for ourselves the same right."

We have, too, the authority of the leading colonial statesmen of the day—of Mr. Cecil Rhodes, of Sir Samuel Griffith, of Mr. Service, of, I hope, the chairman, of Sir Charles Tupper, and the Canadian Ministry, voiced by Mr. Foster, the Finance Minister, in the recent Budget speech, and whose peroration I take leave to use to like end in respectfully commending to your earnest attention a subject which, in the coming Parliament, will—which must, which shall overshadow and absorb all others—be the issue before the people, come what may.

"Considering this war of tariffs, which is taking place the wide world over, considering the discriminating benefits which are given by some countries and denied by others, it may be worth the careful and thoughtful attention of the Government as to whether or not the time is not approaching, if it is not near at hand, when it will become the duty of this Government to hold out the hand of help to those that help us, to repay favour with favour and interest with interest, and to give the best treatment in our markets to those countries which afford to us the best treatment in their markets."

DISCUSSION.

Sir CHARLES TUPPER, Bart., G.C.M.G., C.B., desired first, not only in his own name, but in that of all the representatives of the self-governing colonies in London, to welcome the Chairman, who by his high character and great ability had obtained the confidence of the people of one of the most important colonies in Australasia. He had no doubt that he would be able to render the same valuable services to his country and to the empire in his present position as he had done in Victoria. Colonel Vincent had so completely covered the ground in the paper as to leave very little more to be said. He had referred to that being Her Majesty's birthday, and in thinking of the immense advance made by the British Empire during the present reign it was but right to call attention to the fact that great as that advance had been in every portion, in no part had the progress been greater than in Her Majesty's colonial possessions. The course advocated by Colonel Vincent was making steady and marked progress, though in a conservative country like England one could not look for such rapid action on the part of the public as in newer and more enthusiastic countries. Still, having watched closely the progress of events, he was

satisfied that this great movement for uniting together in closer bonds, by means of the universal tie of self-interest, the mother country and the colonies, was making rapid headway. What progress and prosperity might not colonial development have attained had not the Machiavellian policy of some astute Belgian or German outwitted the British Government long ago, and succeeded in putting these manacles round the country which prevented the fostering of inter-imperial trade. Too much importance could not be attached to the advantage of relieving England and her colonies at the earliest possible moment of these obstructions. He did not believe the difficulties were so great as some supposed, and that all that was necessary could be done without doing any injury to the general trade of the country. The trade returns showed that it was not England which was deriving a profit from the trade with Belgium and Germany, but those countries themselves, and therefore the objectionable clause might be eliminated without danger of interfering with other portions of existing treaties. It was established beyond controversy, that however beneficial trade with foreign countries might be to England, it was infinitely more beneficial to develop trade with the colonies. But there was another point, not specially dealt with in the paper, which, in his judgment, out-weighed even the commercial advantages of such a policy, England possessed in Australasia, South Africa, and Canada, boundless fields for development, which could not be rivalled in any part of the world, and thus had not only the opportunity of building up an enormous and valuable trade, but, as the result of that, those great outlying possessions would become the right arm of English power. There need be no apprehension with regard to their neighbours on the great Continent of America if, under the development of this inter-imperial trade between Canada and the mother country, population and industry were thrown into that great Dominion, which would furnish happy and comfortable homes for from 40,000,000 to 100,000,000 of people at no very remote date. They were all indebted to Colonel Howard Vincent for the ability and energy which he devoted to this great work, both in and out of Parliament, and he had no doubt that, at no distant day, his efforts would be crowned with success.

General LAURIE said he was only entitled to speak as a late member of the Canadian Legislature, and as Sir Charles Tupper had already spoken on behalf of Canada, he should not be justified in taking up time by going over the same ground. They were indebted to Colonel Vincent for pressing this great question in season and out of season—if, indeed, it could ever be out of season to press the importance of inter-imperial or international trade. He preferred the latter word, because the word imperial had an unpleasant sound to many in the colonies, who thought it implied an overshadowing of the colonies by the mother country. He knew that was not the intention of those who used the term; the object was to build up one great nation, to use every means, and especially to add the force of self-interest to that of sentiment, in order to do so. What Lord Salisbury said at Hastings about Canada would equally apply to Australia; it was essentially a union of hearts, but they desired to strengthen that union by the ties of self-interest. Colonel Vincent's appeals had met with a hearty response in the Canadian Parliament, and he hoped an expression to the same effect would come from Australasia. True, they had other questions to decide there, and it seemed to him that a union of the Australian colonies must precede a fiscal arrangement with the mother country; but a fiscal union would not be practicable. The colonies had to raise their revenue in their own way, to meet charges for the development of their own countries, and so on, but a preferential arrangement between themselves and the mother country, freed from the fetters of the treaties to Belgium and the Zollverein of Germany, so that they could make their own tariffs, and give Great Britain an advantge in the colonial markets, and possibly obtain similar advantages in the home markets for their produce, would be the means of drawing closer the ties between the great branches of the Anglo-Saxon race. They held already such a position in the world as would enable them, if so united, to exercise a commanding influence over the policy, and in fact over the actions of the whole world. Colonel Vincent had shown that the colonial trade was of the greatest possible value, that it would become of growing value if fostered, and that it met the decline of trade with other countries, and he believed that his proposals would commend themselves to the British electorate.

Mr. C. M. KENNEDY, C.B., said—We are very glad to welcome Colonel Howard Vincent in this room to-night, and have listened with much interest to his paper. His best exertions have now been devoted for many years to objects of the greatest importance to the working-classes of this country; and of vital consequence to the welfare of the whole empire. This subject has been brought before us very opportunely: the questions at issue are now in men's minds; the export trade of the country is our great concern—all our interests depend on it. In a month's time a general meeting of the Chambers of Commerce of the empire is to be held in London; and the suggestions which will be the outcome of their deliberations are awaited with no ordinary solicitude. The position of the empire—of the mother country and of the colonies—is marked out for us by the conditions of our life: we are component parts of one race and nation, and the welfare and greatness of the whole is inseparable. Much is now said in certain quarters against the economic policy of some of the colonies. But there is little in these remarks—they are often of that description of sympathy, which is likened to mustard without beef,

or else they arise from *doctrinaire* ignorance of the actual position of the colonies. In the early days of a State, internal revenue is not to be depended on, large direct taxation is out of the question, and a Customs' tariff is a financial necessity. Even in settled countries, the Customs is a branch of revenue which it is not within practical policy to discard; and to speak against Customs' duties in the colonies, and to try to create prejudices by vague denunciations of what is called protectionist policy, is, to use a very mild statement, a misrepresentation of facts. We must remember that economic theories are not universally true; they are only true under the exact application of the conditions which they postulate, as Professor Marshall says, "in a very narrow range of circumstances, which happen to exist together at one particular place and time." And we must remember, further, that men understand their self-interests very differently in different ages and conditions. So we need not be afraid of independent judgment, and may set aside boldly asserted *doctrinaire* opinions, put forward under the sound of great names, which we are told must not be discussed but be accepted implicitly, without any inquiry or question on our part. With regard, however, to what Colonel Howard Vincent has said as to the attitude of Her Majesty's Government, no one can fail to recognise that the questions which he has brought forward have to be regarded from various points of view, and that, in some respects, they present considerable difficulties; he is, therefore, under a misapprehension in thinking that there is any want of good-will on their part. The important question before us this evening is well within our functions. We are the Society for the promotion of Commerce as well as for the advancement of Arts and Manufactures; it is quite within our functions to consider the means whereby markets now open to our trade may be made more secure, and the means whereby the obstacles which hostile tariffs interpose to its development may be overcome. Colonel Howard Vincent has foregone the ease which wealth and position afford in order to attract attention to the matters of deep public interest. He has visited the colonies to obtain personal knowledge of the subject he has brought before us. Many economists, however, shrink from these investigations, and use hard words instead of arguments. I do not wish to enter into details of controversy, but in view of forthcoming discussions I may advocate free inquiry and a full statement on each side of the points at issue. We cannot fail to recognise that Colonel Howard Vincent seeks to attain objects which will strengthen the development of the empire in the present glorious reign, which are calculated to bind together the various populations of the empire, and to promote and perpetuate their welfare as a prosperous, contented, and united people.

Mr. H. J. Pettifer said all parties were agreed as to the desirability of encouraging trade with the colonies, that it would be a grand thing for this country, and probably for the colonies also, if the trade could be very greatly extended; but the difference of opinion arose when one began to talk about the best way of doing it, and he should have liked Colonel Howard Vincent to go a little more into detail about it. It was not the disease that needed discussing, but the remedy. Everybody agreed that the country was injured by foreign competition, but directly you began to talk about putting a duty on silks, satins, velvets, &c., the trouble began. It was very easy to get the working men in the large manufacturing districts to agree to preferential duties in favour of colonial, as against foreign, products, &c. You could show them how they would benefit by it, but then you had to go to the English farmer, and show him how he would benefit. He had tried that himself, and had spoken of preferential duties on Canadian and Indian wheat; but the farmer objected that, if he were going to be ruined by foreign competition, it did not matter to him whether that competition came from Canada or the United States. Still, you might convert even the farmer, if you could show him that, by imposing preferential duties, the burden of taxation which he now had to bear would be lessened. But then you had to go lower down, to the man who now, whether for good or harm, had the control of the country in his own hands, the agricultural labourer, and there you found the real difficulty. When you came to talk to the Wiltshire labourer with his 10s. a week, you had great difficulty in exciting any enthusiasm in him about the colonies, the only thing you could impress upon him was that it would give him a better field for emigration. But then both sides wanted to stop emigration, and district councils and parish councils were talked of as a means of helping him in his own village. The spirit of patriotism had not much force, he was afraid, amongst his class. He hoped Colonel Vincent would go a little more into detail as to the means for developing the colonial trade.

Mr. A. K. Donald said he was disinclined to believe that the best way of encouraging trade in the colonies was to set up a tariff barrier against other nations, and doubted whether the increased trade with the colonies would counterbalance the falling off of commerce with other nations. Many people asserted that the goods supplied by this country were not what they ought to be, owing partly to lack of technical education on the part of the workmen, and partly to unscrupulous greed on the part of manufacturers, and that consequently colonial customers preferred to buy elsewhere. A hostile tariff against continental nations and the United States would not make the British manufacturer more honest, and consequently the colonial customer would in all probability still prefer to make many of his purchases where he did now. Though it was true that trade in the colonies was growing rapidly, it could not be assumed that it would con-

tinue to grow at the same rate. The colonies did not pretend that their tariffs were imposed for revenue purposes only, but acknowledged that they were for the purpose of protecting and fostering their own industries. The colonies were endeavouring to become—as all countries ought to be—self-supporting, able to produce everything they required within their own borders. That being the case, it seemed to him that the real problem was not going to be permanently solved by endeavouring just for a time to foster the colonial trade. The real way to face the difficulty would be to find some way to make England herself self-supporting; and though that might sound ridiculous to some people, there were a number of authorities who maintained that under a better system of cultivation we could enormously increase our production of food. It seemed to be assumed in the paper that goods which came here from France or Germany came gratuitously, nothing being sent in exchange for them; if that were not so, he could not see how it was to the disadvantage to exchange commodities with those countries. It was quite true that English capital made waterworks aud tramways abroad, and the profits on those investments which were imported here did not directly represent an exchange of labour, but he did not suppose Colonel Vincent suggested that a present should be made of those public works to the communities for which they were constructed. The exchange which took place between England and any other country might be quite as beneficial to English labour as that which took place with the colonies. It was all very well to say that more labour was put into goods sent to the colonies than into those which went to the continent, but were they to refuse the continental trade altogether because it was not exactly what they wanted. From France we received a large amount of millinery and other things desired by the feminine part of the population, besides wines, &c., and he feared it would be rather difficult to replace these articles by goods from Quebec or Montreal; they would not be appreciated by London ladies. But that was what it must come to if these proposals were carried out in their entirety. He could not tolerate the miserable pinchbeck, so-called patriotism, and talk about our kith and kin. After all flesh and blood in France, Germany, or Belgium, was flesh and blood still, and those people were of as much interest to him, though they might not be his 99th cousins, as people who lived in Tasmania or the West Indies. He hoped the people of this country would never again be made enthusiastic over these old-fashioned worn-out ideas; but that their sympathy would be as wide as the human race itself.

Mr. Stephen Bourne said that the paper was extremely interesting and useful, though he could not altogether agree with its scope and effect. No one could appreciate more deeply than he the importance of our colonies, and his experience of them dated back to a time before Her Majesty began to take any part in Imperial matters; it had ranged over a large part of the British Empire. He had relatives in several colonies, and never faltered in his belief that the source of England's greatness would be found in the support of her colonial possessions. Notwithstanding the remarks of the last speaker, blood was thicker than water, and he thought we ought to give our first consideration to the welfare of our brothers, sisters, and cousins in the various portions of the empire which they had brought under British sway. But there might still be a question, what was the best means of effecting this end? He would not criticise the figures on the spur of the moment, or attempt to draw a different lesson from them, but he could not help feeling that they had not yet got to the bottom of the matter. Colonel Howard Vincent, while enhancing the value of the colonial trade, seemed to ignore the value of the foreign trade. Though the colonists were large purchasers, the exports to them, to a great extent, represented investments of capital transferred there from England in the shape of goods; and therefore, unless we sent a larger amount of capital to the colonies, we were not likely to increase the colonial trade to a great extent. In fact, any such extension as was fostered by differential duties, would be more than compensated for by the loss of foreign trade which would result from it. The great need of the colonies was, first, capital to develop their resources, and then population to work them. He had always contested the notion that this country was overpopulated; the fault lay in our economical conditions, which did not permit of our properly distributing that population over the empire. His experience of the colonies taught him that the result of differential duties would be to divert a large amount of colonial labour from its legitimate occupation in developing the natural resources of the country, and sending their products to us in exchange for manufactures, thus becoming competitors with our own capital. Some years ago, when he visited Canada, he found heavy differential duties levied against English cotton manufactures. He had always been of the opinion of Lord Meath, that what we wanted was an extensive State system of colonisation, helping to remove those who would be useful on the other side, but were overcrowded here. He did not advocate sending paupers abroad, but if we sent a large number of those who were above the rank of paupers, we might save many more from degenerating into that condition. If one-half of the £8,000,000 squandered in the maintenance of lives comparatively useless here were spent in transporting them to our own colonies, we should benefit ourselves and the colonies likewise. If there were plenty of labour and capital, trade must follow its own natural course. Why was it that Englishmen going to the United States with capital and machinery, or to other foreign countries, were not able to compete with others? He was tired of

hearing that Englishman needed protection, and did not think a country like England ought to stand in need of protection from any country in the world. Look at tea. In his early days, China was the source from which tea was derived; but, under perfectly free trade, our own India and Ceylon tea had practically driven it out of the market. Then take the meat trade of New Zealand—where he had a son, and was therefore much interested in it—that had very largely developed, without any protection at all in this country. If New Zealand would take our manufactures in exchange for their meat, instead of setting up manufactories of their own to compete with us under differential duties, that trade would rapidly increase, and, in proportion as it grew in accordance with natural and not artificial laws, it would contribute to the prosperity of both countries. It was quite clear the tendency of the paper was that we should follow the example of America, which permitted perfectly free trade between all the territories in the Union; and, so far, he agreed with it. There ought to be a uniform tariff for all parts of the empire, and the question between him and Colonel Vincent would be, whether they ought to supplement that by imposing differential duties against foreign nations? He did not think that would produce the grand results which Sir Charles Tupper seemed to imagine. The great growth in the colonial traffic had taken place under free trade, and we had become carriers for all the world through free trade in shipping. If we confined our trade to the colonies, we should lose a large amount of profitable employment. At the same time he never shared the sanguine views of Cobden, that when we introduced free trade the whole world would follow our example, and thought a great mistake was made at that time. There was a tendency at present to draw a restrictive line against England, and that should make us withdraw our capital from foreign countries, and place it in our own colonies. But there was another reason why protection abroad was largely supported by those who were free traders at home. Some of these men had large capital invested in protective countries, and drew large profits from protected manufactures there. The establishment of free trade in the United States would be the severest blow which could be levelled against the manufacturing industry of Great Britain, and from that point of view he was inclined to hope that it would be long before she adopted it. Still no doubt we were suffering from the effect of protective duties, and it was a question how we could counteract that. He felt we had a right to say to foreign countries that if we admitted their goods free, we insisted on being placed on equal terms. Free trade with all the world was the goal to aim at; if protection were carried out all round, it would enhance cost everywhere, and do no good to anyone; but we had a perfect right to say if you do not accept the hand of friendship which we hold out to you, we will withdraw it. Such a policy could have been carried out without difficulty when Sir Robert Peel first introduced free trade, but he doubted if it was possible now. Still, it was well worth inquiry. Twenty years ago, if we had refused to admit French wines and silks free unless she admitted our woollens and cottons on the same terms, it might have been done, and even now he believed the trade was far more important to France than to England, and that they might be brought to reason. It was in this direction he should be inclined to proceed, rather than by imposing preferential duties in favour of the colonies. He looked forward to unrestricted intercourse between the whole world, and then our trade would be vastly extended, with our colonies and with other countries as well.

The CHAIRMAN, in proposing a vote of thanks to Colonel Howard Vincent, said that he had learned a great deal from the paper and the discussion. He came from a colony where though there might be individual free traders, he was quite sure that no one would have a chance of being returned for more than one or two constituencies who stood on free trade lines. The allusion made to the Queen's birthday reminded him of the fact that the colony he represented was younger than himself by four or five years. When he was born no white man had ever stepped, with a view of remaining, on the territory of Victoria. The whole of Australia was comparatively young, but it was a remarkable fact that the imports and exports of Australia to-day were greater than were those of Great Britain when the Queen ascended the throne; and, that being so, what could be hoped for in the future. One gentleman had said that he did not see why they should not treat Belgians and Germans in the same way as their own kith and kin in the colonies; but he could give one very important reason why they should be treated something differently. There was not the least prospect, under any circumstances, of the colonies ever going to war with England, but there was a possibility of the most friendly foreign nation going to war, and if that time ever came, the colonists, would be England's warmest friends; they were as loyal to the British crown in Australia as they were in England. He did not believe, as Mr. Bourne did, that there would ever be free trade all over the world; he did not think it possible, considering what human nature was. Each colony must look to its own interest. They had heard of agricultural labourers in England getting 10s. a week; he did not know of anyone in Australia, who was worth his salt, who got less than 6s. a day, and how was it possible for the man who paid 6s. a day for his labour, to compete with him who only paid 10s. a week? The man who paid higher wages must protect himself against the competition of cheap labour. Then another most important question was the value of capital. In London, he found you could discount a good bill for three months at about 1 per cent.; in Melbourne, he could not get the best bill discounted for three months for less

than 6½ per cent. If one man could borrow money at 1½ per cent., and the other had to pay 6½, how could they compete on equal terms in the same market? Another important point was that of local federation; he thought it was absolutely necessary to have a federation of the Australian colonies before they could come into union in any way with the home authorities. At present, Canada spoke with one voice for the whole Dominion, but he could only speak for about one-seventh of the colonies of Australia. Where every colony had its own particular policy, it would be very difficult to get unanimity. When federation was established, they would all speak with one voice, as Canada did now. A year ago, in February, when they had a meeting in Sydney, he thought they were in a fair way of getting federation, he having been the convener of the gathering; but it was found there were difficulties in the way, and at present they were not advancing much in that direction. Of course the next thing would be to have free trade amongst their own colonies, but they would undoubtedly have a protective tariff against the outside world, including Great Britain. It might be possible, in the course of time, if Canada took the lead, in giving Great Britain the benefit of preferential duties, and the effect was beneficial, that Australia would follow the example. This paper put the matter from a different point of view to that from which it was approached in the colonies. They felt that while a few years ago they were encouraged, and considered, there was now a spirit of hostility abroad against them, especially in the financial world, and the financial press was advising people to lend their money to South America, Greece, or any country rather than the Australian colonies. If they had ever even hinted at repudiation, or made default in the payment of interest when due, he could understand it, but they had always fulfilled their contracts in every particular. There was recently a general election in Victoria, and all sorts of candidates came forward; a number of labour candidates, and even some Socialists, but there was not a suggestion in any reported speech of anything approaching to a repudiation of their financial engagements. They felt, therefore, that they were not being done justice to, and that if England wanted the volume of trade extended, she must be a little liberal in advancing capital when it was required. Every shilling of money lent by England was spent in English goods, and it all went to develop the resources of the country. They had spent large sums in constructing railways which were not, and could not be, immediately reproductive, but indirectly they were, as they raised the value of the land from 10s. up to, it might be, £5 an acre. This year a large quantity of wheat was being sent to England, whereas but for the railways they would not have been able to supply even their own population. With regard to emigration, it was sometimes complained that they did not spend some of the borrowed money in importing labour. He did not know what the working classes in England would think of it, but certainly in Australia they would not think it right to tax their constituents for the purpose of paying the passage of other working men to come and compete with them. They were ready to receive all who came at their own expense, but they would not spend the public money in bringing them. They considered they did their duty in employing the people at fair wages and giving them an opportunity of earning a good livelihood, and making provision for old age. There was no Poor-law, and they were anxious not to have one, though there were people requiring assistance occasionally. He should take care to send copies of this paper to Victoria, where he was sure it would be read with interest and instruction, but he was not sanguine as to the views it contained being speedily adopted. He was sometimes astonished at the way in which free trade had gone mad in this country. A few years ago, when in Scotland, wanting to buy a purse, he was told by the shopkeeper he had not one which would suit him, but he should be having a case in shortly from Belgium, where they were made much more cheaply than at home. A few days after, wanting to go into the vegetable market in Edinburgh, he was charged halfpenny admission, and if he had gone earlier would have been charged one penny. Now, to buy a Belgian purse without being taxed at all, and to be charged a penny for buying a cabbage grown on the spot, was a sort of free trade which an Australian could not understand at all.

The vote of thanks having been carried unanimously,

Colonel HOWARD VINCENT, in reply, said it was too late to deal with the various arguments which had been put forward in the discussion, but he might incidentally answer Mr. Pettifer, who probably had more experience in addressing audiences of working men than any one present, in replying to Mr. Donald. The view of the United Imperial Trade League, and of Sir Charles Tupper, and many other able and prominent men, was this. The mother country required certain articles of food and raw materials which were obtainable within the empire, but not in sufficient quantity within the British Isles, and they claimed that we should give our custom, as far as possible, to those who traded with us, rather than to those who would sell us their goods, but declined to buy ours. This state of things did not apply fifty years ago. The colonies were then almost an unknown quantity. But in that fifty years, by means of steam and electricity, the products of the colonies were brought more readily to hand than the produce even of the extreme corners of our island at that time. The cause of the displacement of Chinese tea by India and Ceylon was that in the one case all the resources of modern science and machinery had been applied, and in the other these things were entirely neglected. Besides, tea,

which was an article of daily consumption, was enormously taxed, and as it could not be produced in this country, the whole of the duty had to be paid by the consumer and not by the producer. He had been glad to hear what was said by the Chairman as to Australia. Those who had been there knew that there was no probability of Australia repudiating her public engagements. With regard to the theory of establishing free trade with all parts of the British Empire, to any one who knew anything of the colonies, it was almost an impertinence to suggest that young scattered communities could obtain the necessary revenue by any other means than indirect taxation. If they attempted to send round an income-tax collector, as in England, to inquire what profits every one was making, it would produce a perfect revolution, and once setting the match to such a flame, no one could say where it would end. It was impossible to dictate to the colonies what fiscal policy they should pursue; but if there was found to be a willingness to put a lighter duty on British goods than on the products of foreign nations, that would be of considerable advantage to England, and in return for that advantage we ought to give an advantage to colonial products in English markets, and to buy of them as far as possible, instead of from the foreigner; to take our wheat from Canada rather than from the United States and the same with other articles, rather than from France, Germany, or Spain, which only allowed our goods to enter on exorbitant and almost prohibitory terms.

Sir JOHN ROBINSON, K.C.M.G., writes:—Owing to the length of the discussion and the lateness of the hour, I had not an opportunity on Tuesday last of adding my quota to the tribute of just appreciation paid to Colonel Howard Vincent by various speakers for his admirable and instructive paper upon "The Progress of Colonial Trade." Representatives of Canada and Australia did so in fitting terms. As a South African colonist, I should have been glad to have supported what they said. It is very satisfactory to us, as colonists, to find eminent home politicians ready, as so many are, to recognise the value and importance of colonial trade. Twenty-three years ago (May 19, 1869) it fell to my lot to read before the Society of Arts a paper on "The Progress of the British Colonies." I endeavoured to show, by figures, culled from authoritative sources, how vast had been the expansion of colonial trade, industry, and civilisation during the preceding quarter of a century. At that time, to speak on such a theme was rather like a cry in the wilderness, but the results I was able to show were, at the time, deemed remarkable, if not startling. The figures submitted by Colonel Howard Vincent the other night, show that the ratio of advancement has been, during the subsequent period, even more surprising. Have we any reason for supposing that the pace will slacken? Have we any reason for believing that trade will cease to follow the flag as long as that flag flies? I say nothing here with regard to the political and fiscal questions raised in the paper, and dealt with during the discussion. Enough was said to show that they involve complex considerations not easily disposed of. All the more reason why the discussion of them should be seriously and deliberately proceeded with, and all the more credit to Colonel Howard Vincent for challenging controversy upon issues so momentous to our race and Empire.

Mr. JOSEPH ROBT. CARTER, F.S.S., writes:—As a humble follower of Richard Cobden, it appears to me that by our example we must demonstrate to the world how vastly superior are our own prospects under free trade than under protection—which we have also tried—and to look forward to the not far distant future when the spread of true economic views throughout the world will be accompanied by a demand from the colonial democracy against being "protected" by tariffs that hinder them from competing even with the effete but free workers of the mother country. It is clear that were we to attempt to dictate even to our own self-governing colonies, much less to foreign nations, our intentions would be mistaken and our aims frustrated. We must not forget that, as Mr. Munro candidly admitted, even a federated Australia would probably treat us—like foreigners would be treated too—to heavy custom duties. Self-interest, as interpreted by each country, will remain the chief motive power in fiscal arrangements. And the lesson will not have been misread by ,, ethinking portion of our colonial brethren when they realise that Great Britain is firm in her belief in the expediency as well as the justice of free trade principles. He would, indeed, be a true friend to his country who persuades her not only that it is useless attempting to convert Great Britain from her free trade tenets, but also that a serious injury is being done to his own colony so long as it hobbles along with the broken crutch of "Protection." If we look, however, at the record of our foreign trade for the past fifteen years, as given in the Statistical Abstract, we find that the value per head of exports of British produce from the United Kingdom was in the latest year greater than at any previous time:—

	£	s.	d.			£	s.	d.
1876..	6	0	10	....	1884..	6	10	6
1877..	5	18	6	....	1885..	5	18	4
1878..	5	13	8	....	1886..	5	17	2
1879..	5	11	8	....	1887..	6	1	4
1880..	6	8	10	....	1888..	6	7	3
1881..	6	14	0	....	1889..	6	14	0
1882..	6	17	2	....	1890..	7	0	8
1883..	6	15	4	....	—			

It is to be regretted that an analysis of that trade should show that the progress thereof with British North America and Australia, for example, more particularly the former of our possessions, as compared with our export trade with the United States, does not exhibit that unmistakeable character which those

who talk about "trade following the flag" would lead us to hope and expect:—

	United States.	Brit. N. America.	Australia.
1876..	16,833,000	7,358,000	17,681,000

Miscellaneous.

THE PRODUCTION OF APRICOTS IN DAMASCUS.

The city of Damascus is surrounded by gardens which are composed of fields of apricots furnishing an average yield of from 50,000 to 65,000 quintals of fruit. M. Guillois, the French Consul at Damascus, says that the harvest lasts about six weeks, generally from the 10th June until the end of July. There are six principal descriptions of apricots, the *Sendiani*, *Hamoni*, *Onazari*, *Chahmi*, *Baladi*, and *Klobi*. The *Sendiani* appears the first, about the middle of June; it is an oval fruit of a yellow colour, and of a slightly acid taste. It is consumed exclusively at Damascus. The kernel of this description of apricot is not bitter to the taste. The *Hamoni*, which follows immediately after the *Sendiani*, is the most appreciated; it is small, round, with a glossy skin, and the fruit is perfumed and juicy. This variety, like the former, is consumed at Damascus, and it is subdivided into two categories, the *Hamoni Bakir* and the *Hamoni Lakisse*. The *Onazari* is slightly oval, red, juicy, and perfumed, and resembles the European apricot. The kernel of this description is large, and of a sweet taste, and is easily detached from the fruit. The price of the *Onazari* is about a sixth higher than that of the preceding varieties, and part of this fruit is consumed at Damascus, and the remainder is sent to Beyrout. The three varieties enumerated above are almost entirely used for home consumption, and in a fresh state; while the following descriptions are largely used in the manufacture of preserves, for drying, and for making apricot paste. These are the *Chahmi*, which, externally, resembles the *Hamoni*, but is inferior to it as regards taste, the fruit being dry, and wanting in perfume. The *Baladi*, which resembles the *Onazari* in form and taste, is yet considered to be superior to the latter. The yield of this fruit is about 5,000 quintals, and of this quantity 1,000 quintals are consumed in the fresh state at Damascus, the remainder being used for making dried apricots (*Noukou*), which form one of the principal articles of export from Damascus. This fruit is gathered from the tree when it is completely matured, generally about the 15th June. It is then exposed for three days to the sun on planks, covered with a layer of long straw, care being taken to keep the apricots apart, so that they may not touch one another. The third day, each apricot is gently pressed between the palms of the hands, and again exposed to the rays of the sun, and this operation is repeated until the fruit, perfectly dry, assumes the shape of a flattened disc. This usually takes place in about six or eight days, and the apricot loses about 70 per cent. of its weight. The price of the dried apricot varies between 30 centimes and 1 franc the kilogramme at the time of drying; but at other times, and particularly in the month of Ramazan, when there is a large consumption of the article, the price is doubled. A small quantity of these dried apricots is used in the manufacture of preserves. The remainder is exported to Egypt, Smyrna, and Constantinople, to a value of about £3,200. The *Klabi*, which is a very inferior quality of apricot, is a small, dry, red fruit, and is the only one in which the kernel is bitter. It is exclusively used in the preparation of apricot paste. Apricot paste, known as *Kamar El Dine*, is together with dried apricots one of the principal exports from Damascus. The fruit, when gathered, is crushed in a kind of large iron-wire sieve, and the thick juice which results from this operation is collected in earthen vats, and then spread on planks covered with a layer of oil, where it is allowed to remain two days exposed to the air. At the expiration of this time, the paste is removed and turned. On the fourth day the paste is again removed, and it then has the appearance of a band of leather, very thin, and of a reddish-brown colour, about a yard and a half long and half a yard wide. This is the finest quality of paste. The same operation is repeated once or twice to obtain a second and third quality, each time a little water being added to the residuum of the former operation. The bands of paste are then folded so as to form bundles of about five pounds weight, which are sold according to quality—from 35 to 55 francs the quintal. In the same way as dried apricots, apricot paste is exported to Egypt, Arabia, Aleppo, Constantinople, and also to Belgium. The value of the export amounts annually to about £14,000. As regards the kernels of the apricots, part of these is consumed at Damascus in the manufacture of oil, and the remainder is shipped to France, Germany, Italy, and Austria, the value of this export trade being estimated at £8,000. The value of the yield of apricots in Damascus, after allowing for expenses, is estimated at £28,000. These figures, says M.

Guillois, are sufficient to show the importance of apricot culture in the immediate environs of Damascus, and in his opinion they might be doubled, if an improved system of culture and irrigation were adopted.

THE MINING INDUSTRIES OF NEWFOUNDLAND.

The Colonial Secretary of Newfoundland, in a recent report to the Colonial-office, says that, owing to the absence of roads through the interior, mining is still confined to within a mile or two of the sea coast. The mines worked during last year were for copper ores, antimony, iron pyrites, and galena. The mining industry may be said to be yet in its infancy. The country gives promise of immense scope in this direction. Ores of antimony, zinc, molybdenite, chromite, nickel, hematite, gold, silver, &c., are all known to exist, while of the earthy minerals and non-metallic substances there are great varieties, and in many cases an abundance of material. Marbles, granite, slates, serpentines, ornamental stones, sandstones, limestones, soapstones, and gypsum abound; and asbestos, fluor spar, graphite, mica, &c., are all found there. Clays, suitable for the manufacture of brick and coarse pottery, are abundant. During the past year valuable seams of coal have been discovered in the vicinity of St. George's Bay. Previous to this, the St. George's carboniferous area was generally thought to be destitute of workable coal seams, and as being occupied almost entirely by the lower measures, namely, the carboniferous limestone and millstone grit series. Certain of the fossil plants, and samples obtained during the year, were referred to Sir William Dawson, principal of McGill University, in Montreal, and he gave it as his opinion that the specimens sent indicated a development of the coal measures not unlike that of Eastern Cape Breton, with which the beds may be connected under the gulf; and he stated that the Government of the Colony would do well to inform the English Government of the value of the coals on the west coasts, and their prospective importance to Britain and Newfoundland as well as to the other colonies. He added, "you have the nearest coal to England on this side the Atlantic." An investigation in the section of country referred to has brought to light 27 feet of coal, which is but 10 feet less than that of the North Sydney section. The analysis of this coal gives a per-centage of carbon not inferior to that of Cape Breton coal. This, together with the large deposits of magnetite existing in the same locality, cannot fail, says the Colonial Secretary, ere long, when capital and skilled labour are brought to bear on them, to add greatly to the prosperity of Newfoundland.

HOP GROWING IN BOHEMIA.

The United States Consul at Prague, in a recent report, says that large breweries all the world over always keep in their storehouses at least a small quantity of Bohemian hops, although the price paid is frequently a high one. This fact is a high tribute to the excellence of the Bohemian product, the superior qualities of which are attributed to peculiarly favourable conditions of soil and climate, and to careful and well-tried methods of culture. Since the sixteenth century, hops have had their home in Bohemia, and their fame, then already established, has been maintained and increased, and hop growing still continues to occupy a position of the first importance among the various forms of agriculture. The hop gardens are not extensive, and hop growing is confined to a comparatively small area, while the so-called hop belt is a limited one. The total area under this cultivation amounts, according to the latest statistical returns, to about 26,000 acres, and this is divided into districts known under the names of the cities around which they centre. The largest and the best known is the Saatz district, with an area of about 10,000 acres. The neighbouring district of Rakonitz, with an area of about 600 acres, produces a grade of hops very similar in quality to that of the Saatz district; then come the Auscha district, with an area of about 4,000 acres, the product of which is not considered as good as the Saatz hops, and the Dauba district, with an area of some 2,500 acres, producing an inferior grade of hops. The most celebrated of these districts is the Saatz, and the hops grown there are claimed to be the best in the world. The hops of the Saatz district are again subdivided into *Stadt*, *Bezirks*, and *Kreis* classifications, according to quality, and the *Stadt*, or city hops, are the highest grade, while the *Kreis*, or circuit hops, are supposed to be somewhat inferior. In the Saatz and Rakonitz districts the hops are grown under similar conditions, and the products differ very little. The hops grow in a ferruginous, reddish clay soil, along the banks of the River Eger, while the region is protected from the cold north winds by a spur of the Erzgebirge, and the only prevailing winds are from the west and south-west. The elevation is about 800 feet above the sea level, and the mean temperature during the year about 7° Réaumur. The excellent qualities of the hops is ascribed to the peculiar properties of the soil, and to the very slight atmospheric depression. The hops of the Saatz, Rakonitz, and Auscha districts are all known under the general name of red hops, while the Dauba hops are called green hops. The distinguishing marks of the Saatz hops are a long flower, closed at the top with innumerable leaflets—from a hundred to a hundred and fifty—which are as soft as velvet to the touch. They are characterised by a delicate spicy aroma, and the bitterness is greatly appreciated. The flower, when ripe, is of a greenish yellow colour, with a slight reddish tint. Dauba hops, the type of green

hops, have a round flower with fewer leaflets—from forty to sixty—and the odour exhaled somewhat resembles garlic. The colour of the ripe flower is of a yellowish green. Red hops form three-fifths and green hops two-fifths of the total crop. Outside the regions above mentioned, the cultivation is carried on only on a small scale. The average crop in Bohemia is 9,000,000 lbs. in round numbers. The average yield per acre is not large, in the Saatz district it is between 350 and 450 lbs., while in the Auscha district, in a good season, there is a yield of 600 lbs. to the acre. The labour required for the cultivation is cheap, and hop-pickers receive about tenpence for a day's labour. With a view to securing a uniformly higher standard of hop culture there have been established, within the last two years, technical schools for the study of hop culture at Rakonitz and at Laun. These schools receive financial support from the Government of Bohemia, and also from the cities and districts where they are located. Being situated in the midst of the hop districts, every opportunity is afforded for practical work. In connection with the Rakonitz school there is an experimental hop garden, where innovations in cultivation are tried. The courses of instruction offered are both for students attending regularly, and for farmers desiring special instruction. Among the regular courses of instruction are hop culture, theoretical and practical from a botanical and practical standpoint, treatment of the soil, choice of the young plants, fastening of the poles, selection of the poles, hop picking, hop sorting, &c. The attendance at the schools has so far been considerable, and many students have come from other countries. The results have been so satisfactory that it is expected that hop culture will show a decided improvement as the schools become older and the students turn the knowledge acquired to practical use.

Notes on Books.

FOUR NATIONAL EXHIBITIONS.—By Charles Lowe. London: T. Fisher Unwin, 1892.

This book is intended as a record of the four Exhibitions which were held at Earl's-court in the years 1887-8-9-90, American, Italian, French, and German. The idea of holding in one country an Exhibition of the products of another was an original one, and that it should have been carried out with a reasonable amount of success for four successive years in London is a fact that certainly has to be noted in the history of Exhibitions. Mr. Lowe gives a very full, naturally a favourable account of the origin, rise, and progress of the scheme, a scheme quite worthy of record, and one reflecting a good deal of credit on the enterprise of those who conceived and carried it through.

General Notes.

DISCOVERY OF AMERICA.—A programme of the festivities to be held at Huelva during August and September next, in celebration of the fourth centenary of the discovery of America by Columbus, has been received from the Foreign-office through the Science and Art Department. The proceedings, which are to be of a very varied character, will commence on August 2nd, and will be continued until the 30th September. Among the entertainments which have been arranged for are regattas, sports, balls, banquets, &c.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JUNE 20 ... Geographical, University of London, Burlington gardens, W., 8½ p.m.

Victoria Institute, 1A, Adelphi-terrace, W.C., 8 p.m. Mr. J. J. Murphy, "The Reality of Knowledge."

TUESDAY, JUNE 21 ... Society of Architects, St. James's-hall, Piccadilly, W., 8 p.m. Annual General Meeting.

Photographic, 5A, Pall-mall East, S.W., 8 p.m.

Anthropological, 3, Hanover-square, W., 8½ p.m. 1. Dr. R. Walleschek, "An Ethnological Inquiry into the Basis of our Musical System." 2. Prof. Basil Hall Chamberlain, "Notes on some Minor Japanese Religious Practices."

Asiatic, 22, Albemarle-street, W., 4 p.m.

WEDNESDAY, JUNE 22...Geological, Burlington-house, W., 8 p.m. 1. Professor H. G. Seeley, "Contribution to a Knowledge of the Saurischia of Europe and Africa." 2. Professor H. G. Seeley, "Mesosauria from South Africa." 3. Professor H. G. Seeley, "On a new Reptile from Welte Vreden, *Eunotosaurus africanus*" (Seeley). 4. Mr. J. Postlethwaite, "The Dioritic Picrite of White Hause and Great Cockup." 5. Professor E. W. Claypole, "On the Structure of the American Pteraspidian, *Palæaspis* (Claypole), with Remarks on the Eamily." 6. Miss Maria M. Ogilvie, "Contributions to the Geology of the Wengen and St. Cassian Strata in South Tyrol." 7. Miss Jane Donald, "Notes on some new and little-known Species of Carboniferous *Murchisonia*." 8. Mr. J. S. Crawford, "Notes from a Geological Survey in Nicaragua." 9. Mr. F. Chapman, "Microzoa from the Phosphatic Chalk of Taplow." 10. Mr. Bernard Hobson, 'On the Basalts and Andesites of Devonshire, known as Felspathic Traps." 11. Mr. Thomas Tate, "Notes of Recent Borings for Salt and Coal in the Tees District."

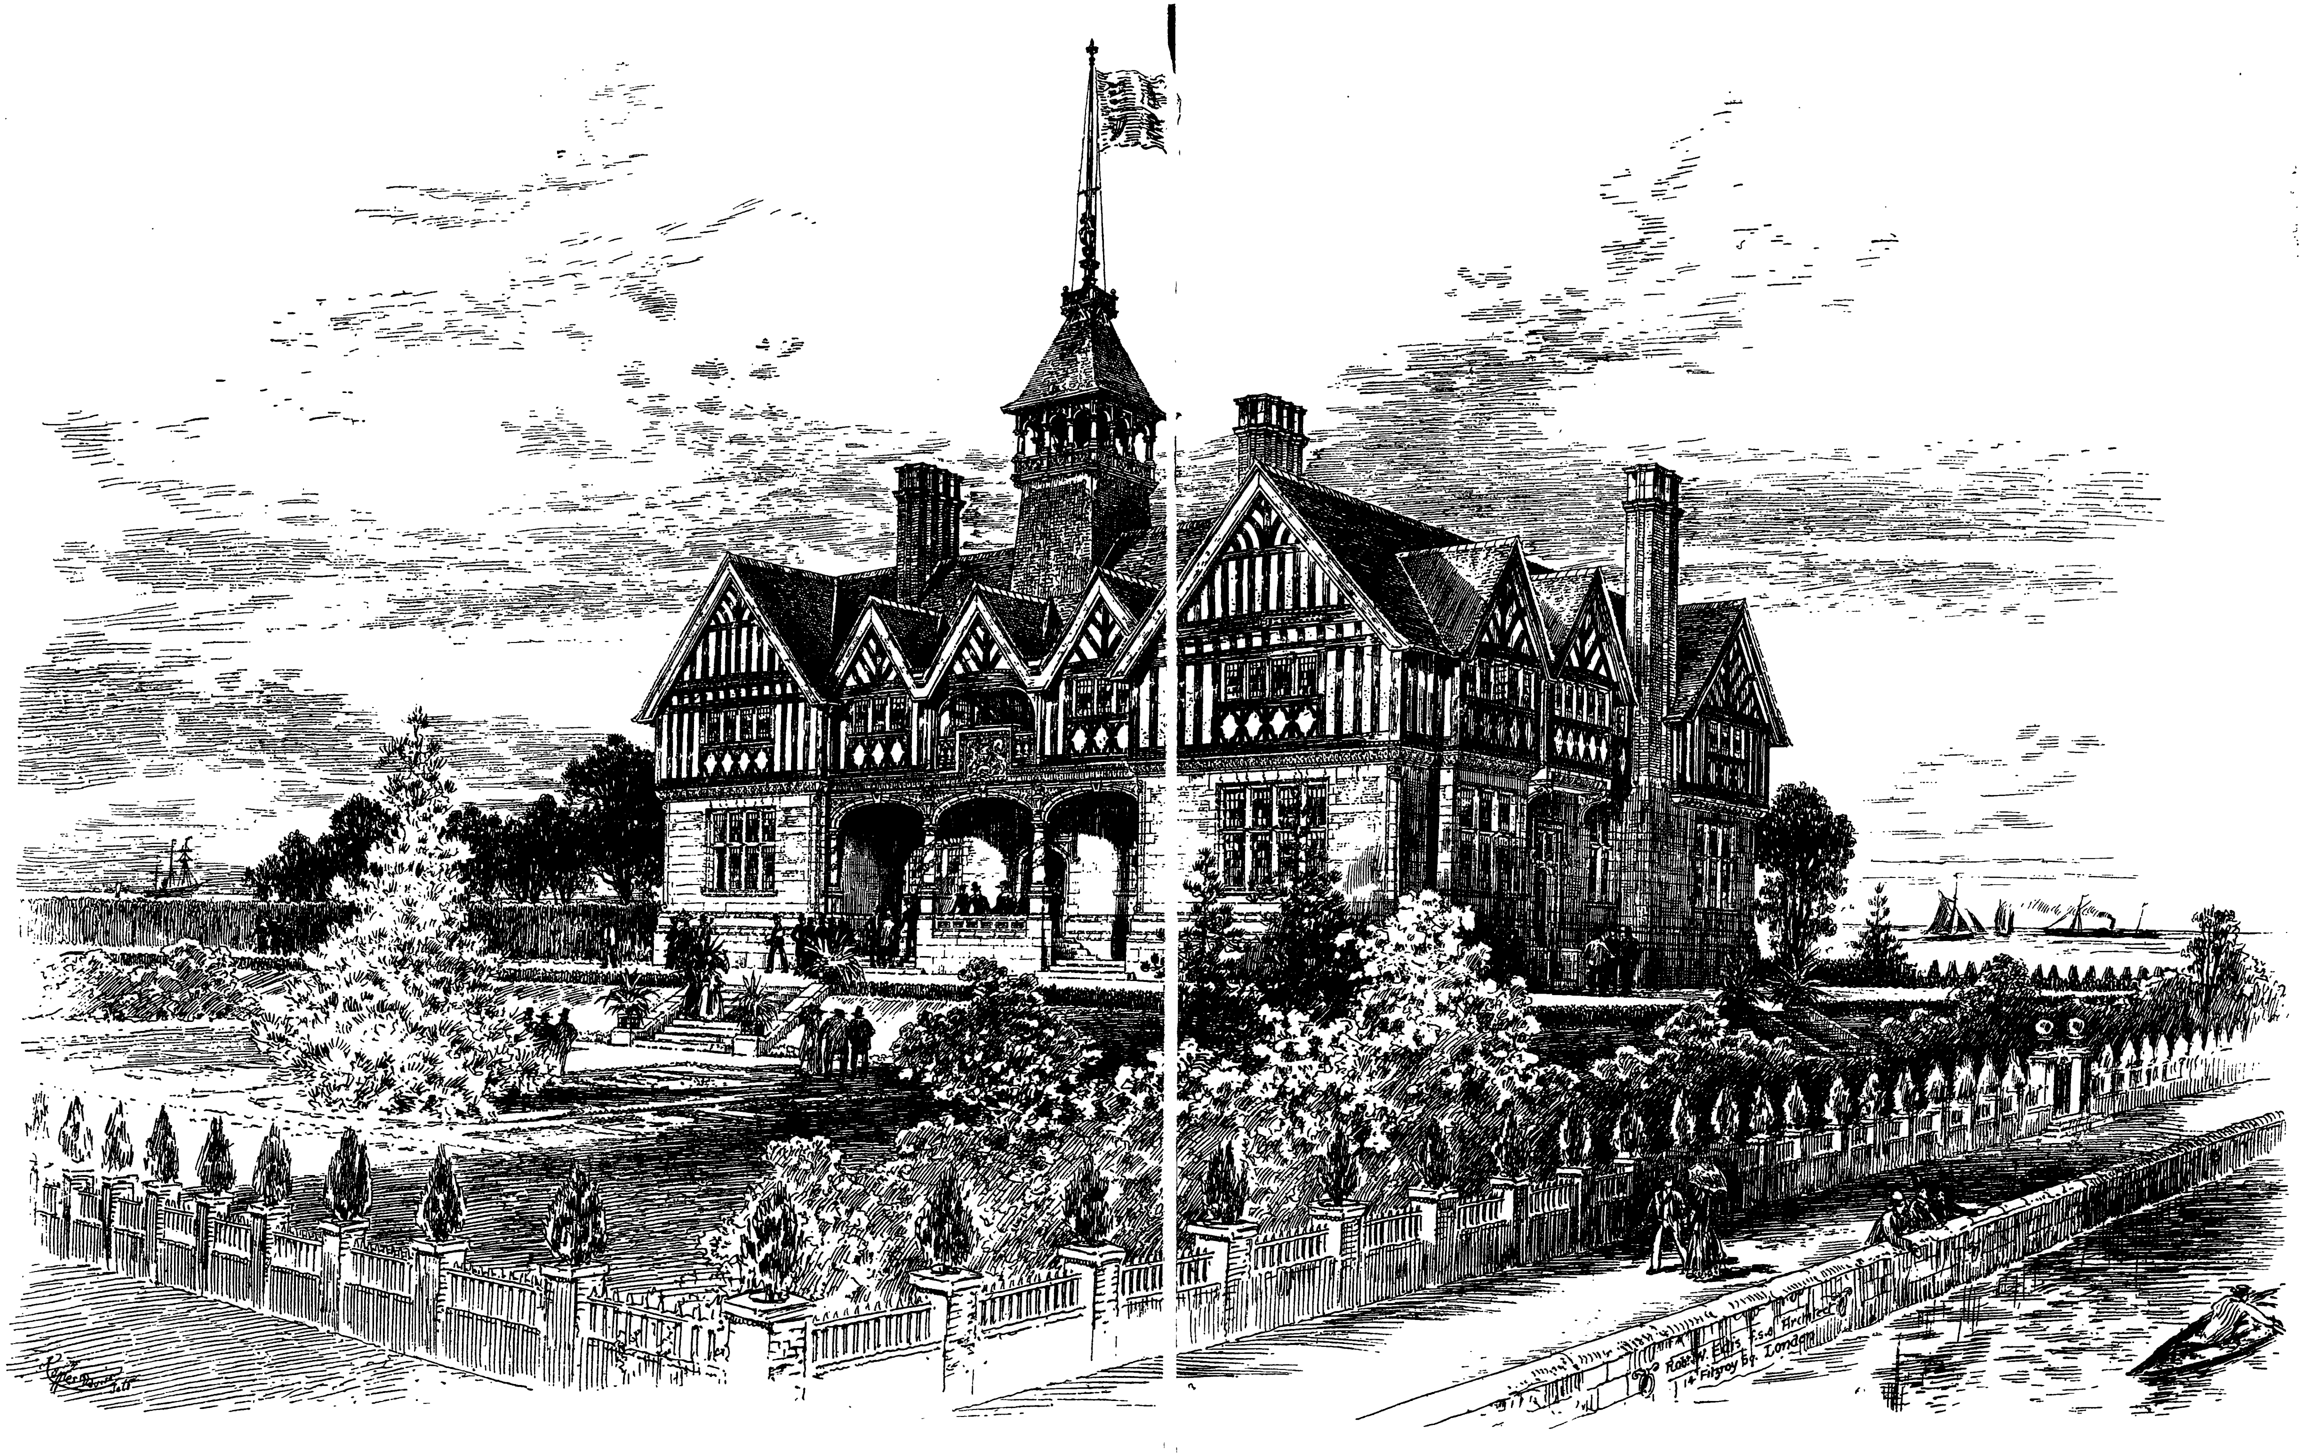
Botanic, Inner-circle, Regent's-park, N.W., 2 p.m. Floral *Fête*.

Royal Society of Literature, 20, Hanover-square, W., 1 p.m.

East India Association, Westminster Town-hall, S.W., 2½ p.m. Major-General A. Phelps, "The Increasing Mortality from Enteric Fever in the European Armies in India."

FRIDAY, JUNE 24...United Service Institution, Whitehall-yard, 3 p.m. Major G. F. R. Henderson, "The Recent French Manœuvres."

Physical, Science Schools, South Kensington, S.W., 5 p.m. 1. Mr. W. B. Croft, "Breath Figures." 2. Mr. E. Wythe Smith, "The Measurement of the Internal Resistance of Cells." 3. Mr. Williams, "Units of Measurement."



CHICAGO EXHIBITION: OFFICES OF THE BRITISH SECTION

Journal of the Society of Arts.

No. 2,066. Vol. XL.

FRIDAY, JUNE 24, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Notices.

FINANCIAL STATEMENT.

The following statement is published in this week's *Journal*, in accordance with sec. 40 of the Society's Bye-laws :—

TREASURERS' STATEMENT OF RECEIPTS AND EXPENDITURE FOR THE YEAR ENDING MAY 31ST, 1892.

14.	Accumulated Interest on Trust Funds	400 0 0	On Deposit with Messrs. Coutts and Co.

The Assets, represented by Stock at the Bank of England, and Securities, cash on deposit, and cash balance in hands of Messrs. Coutts and Co., as above set forth, have been duly verified.

OWEN ROBERTS, }
B. FRANCIS COBB, } *Treasurers.*

HENRY TRUEMAN WOOD, *Secretary.*

J. O. CHADWICK AND SON, *Auditors.*

Society's House, Adelphi, 21st June, 1892.

ANNUAL GENERAL MEETING.

The Council hereby give notice that the One Hundred and Thirty-Eighth Annual General Meeting, for the purpose of receiving the Council's Report and the Treasurers' statement of receipts, payments, and expenditure during the past year, and also for the election of officers and new members, will be held, in accordance with the Bye-laws, on Wednesday, the 29th June, at 4 p.m.

(By order of the Council),

HENRY TRUEMAN WOOD,
Secretary.

CONVERSAZIONE.

The Society's *conversazione* will take place at the South Kensington Museum (by permission of the Lords of the Committee of Council on Education) on Wednesday, 29th June.

The reception by the Attorney-General (Sir Richard Webster, M.P.), Chairman, and the Members of the Council of the Society will be held from 9 to 10 p.m.

Promenade Concerts will be given by the Band of Royal Engineers in the North Court, and by the Band of the Scots Guards (weather permitting), in the Quadrangle of the Museum.

A Vocal and Instrumental Concert by the Meistersingers and Meistersingers' Orchestra will be given in the Lecture Theatre under the direction of Mr. Norfolk Megone. The first part of the concert will commence at 9.15.

Light refreshments (tea, coffee, ices, claret cup, &c.) will be supplied at the usual Refreshment Buffets in the Central Corridor of the Museum.

Programmes of the musical and other arrangements will be distributed on the evening.

Each member is entitled to a card for himself, which will not be transferable, and a card for a lady. The conditions under which the use of the Museum has been granted by the Science and Art Department do not permit the sale of tickets; Members will therefore not be able to purchase additional tickets for their friends, as in recent years.

The cards have now been issued to the members.

MEDALS.

The Council have awarded the Society's Silver Medal to the following readers of Papers during the Session 1891-2:—

To Prof. SILVANUS P. THOMPSON, F.R.S., for his paper on "Measurement of Lenses."

To G. H. ROBERTSON, F.C.S., for his paper on "Secondary Batteries."

To Captain F. E. YOUNGHUSBAND, for his paper on "The Pamirs."

To Prof. VIVIAN B. LEWES, for his paper on "Spontaneous Ingnition of Coal, and its Prevention."

To ROBERT S. MCCORMICK, for his paper on "The Trade Relations of Great Britain and the United States."

To Captain W. DE W. ABNEY, C.B., F.R.S., for his paper on "Colour Blindness."

To F. E. IVES, for his paper on "Composite Heliochromy."

To F. A. PEZET, for his paper on "Peru: its Commerce and Resources."

To Sir EDWARD BRADDON, K.C.M.G., for his paper on "Australia: its Progress and Resources."

To G. H. M. BATTEN, for his paper on "The Opium Question."

To Dr. J. AUGUSTUS VOELCKER, for his paper on "The Agricultural Needs of India."

To JERVOISE ATHELSTANE BAINES, for his paper on "The Administration of the Imperial Census of 1891 in India."

To WILLIAM MORRIS, M.A., for his paper on "The Woodcuts of Gothic Books."

To C. PURDON CLARKE, C.I.E., for his paper on "English Brocades and Figured Silks."

To WILLIAM DE MORGAN, for his paper on "Lustre Ware."

Thanks were voted to the following Member of Council:—

To JAMES DREDGE, for his paper on "The Columbian Exposition at Chicago, 1893."

Chicago Exhibition, 1893.

EXECUTIVE COMMITTEE.

A meeting of the Executive Committee of the Royal Commission was held on Wednesday, 22nd inst. Present: The Attorney-General, M.P., Q C., in the chair; Sir Frederick Abel, K.C.B., F.R.S., Sir Philip Cunliffe-Owen, K.C.B., K.C.M.G., Francis Cobb, James Dredge, George Matthey, F.R.S., Sir Owen Roberts, M.A., D.C.L.

Proceedings of the Society.

APPLIED ART SECTION.

Tuesday, May 31, 1892; Sir GEORGE BIRDWOOD, K.C.I.E., C.S.I., LL.D., M.D., in the chair:—

The paper read was—

LUSTRE WARE.

BY WILLIAM DE MORGAN.

The word "lustre," in its connection with pottery, has not always been used in its present limited sense, but rather as an equivalent of our word "glaze." It has been applied to the glossy surfaces of the Greek, Roman, and Etruscan pottery,* although the gloss upon these is comparatively slight. Nevertheless they are lustrous as compared with unglazed tile or brick. In a more restricted sense the term may describe any metallic deposit on a glazed surface where the decorative effect depends upon, or is enhanced by, reflected light. But even this definition would be now-a-days disallowed by the common understanding of the word, which applies it almost invariably to the special iridescence of the Persian, Arabian, Hispano-Moresque, and Italian majolica. This iridescence, the means by which it has been and is obtained, and more especially the means by which I have myself endeavoured to obtain it, form the subject of the following paper. It is a subject which may be treated either historically or technically, but the two lines of treatment intersect at many points, and it is at these points, if at any, that what I have to say may be of interest. I will, therefore, before describing my own experience, give the shortest possible retrospect of the history of the subject, although in so doing I shall no doubt be going over ground already familiar to many now present.

All investigations seem to converge towards the conclusion that Egypt or Assyria were the earliest nurseries of the art of decorating pottery, which afterwards attained its maturity in Persia. The glazed and coloured terra-cottas from the palace of Darius, brought from Susa by M. Dieulafoy,† and now in the Louvre, show that those who produced them possessed all the materials and almost all the processes known to their successors. But there is no apparent knowledge of the lustre process either in these or any other ceramic productions of remote antiquity, although an accidental stain of copper lustre has been detected on an Egyptian vase in the British Museum. The earliest lustres known are those found on fragments dug from the ruins of Persian cities, more especially those of the city of Rhé, or Rhages, to which a very great antiquity has been assigned. They have been generally accepted as antedating the destruction of the city 600 years ago.* But although Sir R. Murdoch Smith speaks of a possible age of 2,000 years for some of them, this is very conjectural; and until we can find proof of the process being in existence in Persia previous to the Arab conquest in 641, its Persian origin cannot be considered beyond a doubt. However ready we may be to ascribe a Persian parentage to the art of the Arabs,† we cannot shut our eyes to the fact that the area of Arab conquest in the 9th century is almost exactly co-extensive with the distribution of the manufacture of lustres, so far as it is known to us, in the 12th. Before the Arab conquest, decorated Persian ware is known to have existed by surviving samples, all without lustre. As soon as our authentic record of lustre-making begins, it is found throughout the conquests of the Arabs, and nowhere else. In 1154, Edrisi, the Arabian geographer, speaks of it as being then made at Calatayud, in Spain, which was at that date a recent conquest of the kings of Arragon from the

* The gloss on these was a matter of preference, not due to inability to produce ordinary glazes. Deck mentions moulds for pastry, glazed inside, in the museum at Naples, as proof of this.

† These are enamelled with a white tin glaze, according to Deck.

* Possibly, but not necessarily. All depends on the locality and nature of the excavation. An instance, cited by Mr. Henry Wallis, of a fragment found at Brahminabad, and now in the British Museum, does not appear of so old a date as the destruction of that city in the 11th century. It is a piece of silver lustre, probably Persian.

† We may be tempted to the belief that the Arabs got it from the Persians by the splendour of the Sassanian civilisation, but we should distinguish between the knowledge of a traditional process and the capacity for making use of it. Besides, although the Arabs have been called savages at the time of the conquest of Persia, they were the savages who, a century later, were building the mosque at Cordova. Nobody suggests that they learned anything from the Visigoths. Sir R. Murdoch Smith surmises that the Alhambra was really the work of Persians. It is possible, but is not the surmise more the result of a conviction that the Arabs could not have done it, than a result of actual record, traditional or otherwise? There is one Persian lustred tile at South Kensington Museum said to be 1,300 years old (No. 1841. 76). Sir R. M. Smith judges it pre-Mahommedan, because the later artists never represented human figures. It certainly is an exception either to this or the universal absence of pre-Mahommedan lustre. But in the absence of more examples, one exception is as likely as the other.

Saracens. A century before (1040), Nassiri Khosrau testifies that they were made at Cairo. These are, I believe, the two earliest trustworthy testimonies to the manufacture of lustred pottery.

Perhaps the safest judgment as to the origin of the process in modern times is that which makes the Arabs the distributors, east and west, of a knowledge transmitted to them from Egypt or Assyria. It is stopped in its journey eastward at the borders of the Persian empire, and is conspicuously absent from China and Japan. Its non-appearance in the manufactures of these countries may be accounted for by the nature of the materials already in use. I have tried to get lustres on Chinese and Japanese ware, but have always failed; the glazes appear singularly refractory. Other causes may have helped to prevent the Persian or Arabic process going eastward. In the other direction, the course of the Arabs, from Cairo to Tangier, has been said to be traceable by the glazed and decorated wall tilings of their buildings, especially the mosques. No doubt this is in some sense true, but it has been more than once told so as to convey a false impression that the Saracen invaders of Africa built tile-kilns at every station of importance, and that pottery factories were at work in Spain, if not during the time of the Abbasides, at any rate very soon after the establishment of the Caliphate of Cordova. Wall tiles, beautifully decorated, were placed by the historical imagination on the walls of the great mosque at that town, and by implication at Seville and Toledo also. But the tendency of more recent investigation is to ascribe all the surviving examples of Arab wall tiling in Spain to a much later date. However, there might have been wall tiles in the mosque of Abd-el-Rhaman of native manufacture, as fragments of decorated pottery, supposed by some to have been made in Spain about the year 969 A.D., occur in the Museum at Grenada. The construction of the mosque was still going on in the time of the vizier Almansor, who melted up the bells from the shrine of Compostella to make lamps for the mosque, at which he used to work with his own hands. This was in 985. But, if we judge by contemporary descriptions of buildings, these great mosques, and others, such as the palaces of Az-zahra, at Cordova, were marvels of decoration in marble, gold, and ivory, but were entirely without wall tiling. Moreover, mosques of the same period, at Cairo and elsewhere, are entirely without tile decoration.

The next landmark in the history of the subject is the erection of the Alhambra by the Moorish kings of Granada. The old tiles with which its walls are covered are genuine native *azulejos** of the date of the completion of the building, about 1350. They must be distinguished from those placed in the building when it was restored by Charles V. in the 16th century. They belong to the same group of manufactures as the great jars which were found full of coin under the building. The well-known one, of which there is a copy by Deck at South Kensington, is still in the Alhambra, and there is a similar one in the museum at Madrid. These and one or two others are the oldest surviving examples of the practice of lustre in Spain. There does not seem to be any need to assume that they were imported from Cairo or Persia, and we may probably ascribe their fabrication to Malaga. The Alhambra tiles may have been made there too, although in view of the comparatively simple operations involved in the making and firing of the latter, and the vast quantity required, it might be more reasonable to suppose they were made on the spot. It would have been far easier to build a kiln on the works at Granada than to carry all that weight of tiles over the Sierra Tejada. But the pots were quite another thing. They were made for exportation as well as native consumption, and Ibn-Batoutah, an Arab traveller, found the manufacture in full work at Malaga in 1350.

Time, or rather the want of it, prevents my making more than a passing allusion to the

* This word *azulejos* is, I believe, considered to have no connection with *azul*, blue, and is said to be derived from an Arabic word of similar sound. Although the researches of an ignoramus in dictionaries of languages he is unacquainted with have no value, perhaps I may mention one or two perplexing points in this derivation. If I understand Senor Juan Riano ("Industrial Arts in Spain," p. 167), the first mention of the word occurs after 1400. But a different word for tiles is used in King James of Arragon's charter to the potteries of Xativa, namely, *rajolas*. *Rajar* in Spanish means to split or divide into chips, and no one who has ever sliced tiles out of slabs of clay will wonder much at their being called slicings or splittings. It certainly suggests that the word *azulejos*, which also is a distinctly Spanish name for the cornflower, belongs to the Spanish period. If the Arabic word means nothing but tiles, why should it not be a derivative of the Spanish word? Of course I am supposing (from the uncertain way in which my informants write) that it is not a familiar Arabic word, or very ancient. It would be odd if historians accepted as probable the theory that the Arabs conquered Persia and carried Persian art half over Europe, and rejected the possibility of their having carried a word away from the language of Spain after centuries of occupation. My dictionary calls *azulejos* blue Dutch tiles. It is a curious fact in this connection that in the East the important tile *par excellence* is a piece of blue placed over the door of a house to keep away the *Afreets*.

lustred wares of Sicily. There are some examples of what has been called Siculo-Arabian ware to distinguish it from the dark blue pottery covered with small diaper ornament, which is ascribed to Saracenic or Moorish potteries at Calata-girone (about thirty miles from Syracuse), probably of the period of the maturity of the Hispano-Moresque. I believe there is nothing antedating the Norman Conquest of Sicily. But there is documentary proof of the exportation of *faïence* to Sicily from Barcelona, in 1528, which suggests that the manufacture never became firmly rooted. However, we must remember that Sicily had been under the Spanish rule, or misrule, from 1479, and hunting Saracens was a part of their political economy. The desirability of extending the export trade may have accelerated the suppression of the Siculo-Arabs.* I am rather surprised that the near coincidence of this date of the Spanish in Sicily with the appearance of lustres in Italy should not have caused the ascription of its Italian origin to these particular potters and no others. It would have been at least as plausible as the other theories.

One of these had its origin from the existence of *bacini*, or *bacili*, with which the walls of certain churches at Pisa and elsewhere are decorated. Marryat, the historian of pottery, ascribed a Saracenic character to these, and framed a theory to account for them which is so picturesque that I wish it were true.

In 1115, the Pisans made a crusade against Nazaredek, the Saracen King of Majorca, whom they overcame after many mishaps by land and sea. They liberated no less than 30,000 Christian captives from his dungeons, and returned home with shiploads of Saracen prisoners, gold and silver, embroidered garments, and decorated crockery, to say nothing of two large porphyry columns, which they afterwards gave to their allies, the Florentines, and which stand on each side of Benvenuto Cellini's Baptistry gates to this day—an eternal testimony to the truth of the story. The decorated bacini in the walls of the churches at Pisa were supposed to have been placed there as trophies, and, indeed, continued to be thought so until Mr. Fortnum's examination of them in 1868 settled the matter. He made a close inspection of those on six churches at Pisa, and found only one fragment of Saracenic origin. Marryat had the tale of the crusade—which, no doubt, is good history—from Sismondi, but Sismondi says nothing whatever about the cargo of lustred pots. His chief authority is Laurence of Verona, who wrote a poem about the Crusade. It does not seem to contain any allusion to the *bacini* or kindred subjects, but then my failure to find it in 3,000 Latin hexameters is far from conclusive. However, what I rely on is that I have seen no citation from them in Mr. Fortnum's writings. Mr. Fortnum has been over the ground, and had there been a word about the *bacini* in the poem, he would certainly have found it out. The passage in Marryat's history conveys the impression that he did not look behind Sismondi, and indeed that his conjecture was a mere passing surmise, chiefly based on the *bacini* in the church walls themselves.

Another conjecture, which would have been just as good as the foregoing if the dishes had been Oriental in character, ascribes their origin to the Saracen merchant ships captured by the Pisans at Syracuse or Palermo, at the time of their alliance with the Normans in their invasion of Sicily in the 10th century.

Another, the latest I have met with, is that of M. Mely, who tells us that at Tchakindji in the Caucasus, the armorial bearings of Genoa and Pisa occur on mediæval buildings, and that the mosque of Erivan in that neighbourhood is richly decorated with tiles. He suggests that this may have been the point of contact between West and East which caused Italian pottery. But there is no difficulty in finding ways in which the Italians *might have* learned technical secrets from the Saracens. The difficulty is to connect the actual art, as it appeared first in Italy, with any one of the sources to which it has been ascribed.

Majorca has certainly had the preference hitherto. But we have no actual record till

* The Saracen foothold in Sicily dates from 830, and had a certain amount of life in it till about 1072. The period of the Spanish viceroys began in 1479, under Ferdinand of Spain, but was preceded by the house of Arragon (1282). It is true that Jaymé I. of Arragon, in 1239, figures as a benefactor to Saracen potters at Xativa San Felipe, near Valencia. He extended his royal protection to them in return for a small tax. That was his account of the matter. Probably *they* would have said that he charged them one bezant per annum per furnace for leaving them alone. This would be a Moorish gold bezant (called marabotini, or maurobotini), such as occurs frequently (Py. Cycl. article, Bezant) in Arragonese charters. Ferdinand was called the Catholic, having shown his catholicity by persecuting the Moors before their final proscription, and founding the Inquisition; also by refusing to allow Papal Bulls to become valid without the consent of a secular council. The remains of the Siculo-Arabs must have found existence irksome in Sicily from 1479 onwards, and the ruby lustre appears just after this time on the class of dishes ascribed by some to Pesaro, by others to Gubbio.

1442,* when one Giovanni di Bernardi, of Uzzano, in a treatise on navigation, speaks of "the ware of Majorca and Minorca, which had then a very large sale in Italy." To my own thinking, there are two things which account for the prominence given to Majorca. One is the story of King Nazaredek and the conjecture Marryat founded on it about the bacini. The other is the name majolica, applied to lustred ware at first, and afterwards to all Italian *faïence*. But when we come to look for the first use of the word in the sense of pottery, we are referred to Julius Cæsar Scaliger in the 16th century, who says that the recent skill of the Majorca potters has made such clever imitations of Indian (Chinese) pottery, that it is hard to tell them apart, and that these are called after Majorca, all but a letter or so. An antiquity which this record is not entitled to creeps round it in the mind of any unobservant reader when, in close proximity, he reads the line of Dante, in which he speaks of "l'isola di Cipri ê *maiolica*." I feel certain that many who have seen this connection of two writers born over 200 years apart, must have run away with the idea that Dante called earthenware majolica.

There is also the testimony to the importation of Spanish-Moorish ware from Valencia to Italy of Escolano, a Spanish writer, who says that Pisa was the port to which the Moors exported their *faïence*, in exchange for that of Italy. This is a very odd statement. If the merchants of that date (before 1600) really brought *faïence* back from Italy, it must have been something of great value, some article of luxury. It is utterly inconceivable that they should bring back freights of cheap serviceable earthenware to a country famous for its crockery since the days of the Romans, when Murviedro was Saguntum. On the other hand, if rare and highly decorated work came from Italy, where is it now? It is well known that the bulk of the fine samples of Hispano-Moresque were found in Italy, having been exported to the Italians as a favourite article. There should have been a few, at least, of corresponding samples in Spain of imported Italian ware.* However, it is noticeable that testimony of Spanish exports to Italy at an early date should also bear witness to the importation to Spain of Italian ware presumably of equal value. It is also a fact of much importance that, while all this testimony is limited to showing that there was a commercial reciprocity between the Spanish ports and Pisa, the first records of lustred pottery in the north of Italy begin, not at Pisa, but at Pesaro.

Pesaro is a clay centre, and a seat of pottery manufacture from a remote antiquity. Passeri, the earliest historian of Majolica, was Vicar-general of Pesaro, and although he writes with some natural partiality for the town, I believe his conclusions are generally respected, especially as he had opportunities for inquiring into the earlier manufacture which no longer exist. He places the decoration of the mezza-majolica (as the ware came to be called) as early as the end of the trecento period, and the characteristic madreperla lustre towards the end of the quattrocento. He also claims for Pesaro the honour of having produced ruby lustre in 1480. If some of the mezza-majolica at the British Museum is rightly dated, there is no reason why this should not have been the case. At any rate, Pesaro is where we have to look for the Moors, who came and taught the Italians lustre.

Now, Pesaro is a long way from Pisa, and the Apennines are between. It is quite as near Venice, and is a seaport. For every one communication between Pesaro and Pisa in the Middle Ages, there would be a hundred between Pesaro and Venice. And between Venice and Syracuse there would be much more frequent communication than between Valencia and Pisa. If we must have Arabs to teach the Pesarese lustres, why not go to Sicily for them. The fact is, that a mistaken historical clue guided the inquirer to Pisa first, in the case of the 12th century bacini, and it is difficult to get away from it. If another instance of bacini—that of the church of

* I have never seen any notice of the appearance of this ware in pictures of the date. Ugo Vander Goes, the Flemish painter, whom Maso Portinari commissioned to paint the great "Nativity" in the hospital of St. Maria Nuova, at Florence, has placed in the foreground of that picture, an unmistakeable Hispano-Moresque albarello, or drug-pot, with a blue and silver lustre pattern. I do not know if the date of the painting of the pot can be established, but the picture was painted in Italy about 1480. This may be safely inferred (if it is not otherwise known, which, perhaps, may be the case) from the date on the Ghirlandaio Nativity in the Academia. In this the shepherds are clearly painted from the same models, and the influence of the Flemish painter is, perhaps, visible elsewhere. Ghirlandaio was then four-and-twenty, and open to influences; his picture is dated 1485. The relative scarcity of Hispano-Moresque ware in the North is illustrated by the absence, generally, of such pots from Flemish and German pictures. I have never, myself, seen any but this one.

* A dish in the Henderson collection, with Marcus Regulus painted on the face, has a Spanish inscription on the back. Was it an Italian artist's in Spain, or an order sent to Italy by a Spaniard?

Lucera, in Apulia—had attracted attention to the same extent, we probably should now find it equally difficult to get rid of the Moors or Arabs of Calata-girone. For my own part, I do not believe either had anything to do with it, beyond the impulse the circulation of their ware gave to the ingenuity of one of the cleverest races in the world in an age of increasing artistic activity.

I have lately had the satisfaction of finding that this opinion is also expressed in the work of M. Theodore Deck on "Ceramics." M. Deck's opinion ought to have great weight, as he is certainly the most eminent practical potter who has written on the history of the subject.

I have dwelt upon this historical evidence, because it is just one of the points at which the lines of history and technical inquiry intersect. I will now give my version of the other side of the matter.

The technical distinctive feature of Hispano-Moresque ware is that it is invariably on a white ground of glaze rendered opaque by oxide of tin. All the mezza-majolica, the early Pesarese ware, is on the white ground described by Passeri, which had, according to him, been in use since 1300, perhaps earlier. It is not a tin enamel, but a white slip covered with a mixed glaze of lead and alkali, *marzacotto*. Not a single dated example of lustre appears in Italy on a tin enamel till near the end of the 15th century, either at Pesaro or elsewhere. Now I can testify, and so can every potter who has ever made lustre, to the facility and certainty with which it can be produced when tin is present in the glaze as compared with other glazes.

That the Italian potters should learn from a Moorish source, and yet get so little clue to the superiority of this white ground that no experiment in its use should survive, and no tradition be handed down, is most improbable. But it becomes more improbable still at the next step in the history of majolica when, about 1475, or perhaps rather earlier, the tin glaze begins to supersede the white slip. The course the Italian potters took then was to use it not as the glaze *par excellence* susceptible to lustre, but as a whiter substitute for the white slip, glazing it over with marzacotto precisely as they had glazed the old ground. It might be difficult to pronounce certainly on this point from inspection alone, but there is other testimony. Piccolpasso, in his very explicit description of the Gubbio process and Italian pottery generally, in 1548, leaves no room for doubt. He notices the necessity for glazing the tin glaze thinner than the white *terra di Vicenza*, or slip. But there is not the slightest hint that the old marzacotto glaze was ever discarded.

It may be objected that the tin glaze was unknown, or unobtainable. There is strong evidence to the contrary even as to its use by Italian potters, and the tendency of recent research is to place the date of its adoption earlier and earlier.* But apart from this, it was in use in Italy for another purpose long before. Luca della Robbia† had had time to mature his method of covering terra-cotta with it, and to place his two great bas-reliefs above the doors in the Duomo at Florence by the year 1438. So that, however much we strain dates, there is a long period during which the tin enamel was known in Italy, and yet the makers of the mezza-majolica persisted in the use of a ground of their own, while, had they been acting under Moorish instructions, they must certainly have been looking and longing for the more manageable Moorish ground. If Luca got his knowledge (as Jacquemart supposed) from the potteries of Faenza or Caffaggiolo, it makes the combination of circumstances still more puzzling. Faenza is a two days' journey (about 70 miles) for a horseman from Pesaro, certainly not more —and the interchange of *employés* was probably not uncommon.

I believe what I have said would hold good equally whatever view is taken of the exact date of the first Pesarese lustres. The question is a little complicated by the fact that the date of the lustre is not of necessity that of the piece. An unlustred piece of *faïence*, 300 years old, could be put through the kiln now, and no human penetration could discover the date of the lustre. Bacili made at Pesaro in 1450 may have been lustred at Gubbio in 1550.

* See Fortnum's reply to Prof. Argnani, *Academy*, Sept. 6, 1890, No. 957. Dr. Umberto Rossi and Prof. Milanesi date the use of tin glaze in Tuscany as early as 1300–1400.

† The tiles on the tomb of Benozzo Federighi (1456), which appear to be on tin, are among Luca's works. In these, the technical point most prominent is that Luca wanted something golden, or something akin to lustre, and could only get it by cutting out the background in mosaics of a rough sort of pottery gilding. But if he had had his white ground from a Saracen potter, he would probably have lustred the background, even if danger to his other pigments had compelled him to use separate pieces. But there is a disposition to refer to Faenza and Caffaggiolo as Luca's sources of information about tin; and if a small oil-jug in the Henderson collection is rightly ascribable to either, they could make lustre there also.

I leave this part of the subject with many things unsaid, in order that I may not be forced to omit the next landmark in the history. The bottega at Gubbio, and its connection with Giorgio Andreoli, has been considered as the most important of all from an artist's point of view. Maestro Giorgio was a sculptor, a pupil of Luca Della Robbia, who took to pottery and worked at this bottega, which had already produced some fine lustre work, perhaps as fine in all decorative respects as any which followed. The free use of ruby distinguishes this from the mezza-majolica, and the Maestro Giorgio productions may be again distinguished from it by a varied character in the ruby, and a finer white ground. The aim evidently is a transparent ruby to be used as a pigment. To my own thinking, the work throws doubt on its suitability for this purpose. However, there can be none that in his time the colour attained its greatest brilliancy. The dates range from 1518 to 1537, the later examples being by his son and other contemporaries, who carried on the work a little longer. But all lustres disappear from Italian decorative work about 1550, so that a period of 60 years covers the whole production. I have before spoken of the longer lifetime of the Hispano-Moresque process, but, in both cases, the disappearance was only that it ceased to be used on elaborate work; as certainly in Spain, and possibly in Italy, the practice has never completely died out.

It is more difficult to account for its disappearance so long before the collapse of the arts in the 18th century than for the vigorous and successful attempts to out-do the Moorish pottery in the age of Renaissance. It may satisfy some to say that a change of fashion did it; but this is only substituting one phrase for another, and very nearly means nothing at all. A plausible surmise is that its use became incompatible with the careful and dexterous brushwork on fresh-dipped enamel, which reached to such perfection at Castel Durante and Urbino. The greater an artist's success in manipulation, the less is he disposed to incur the risks of an uncertain firing. A lustre-kiln may spoil the whole outright, or even if the lustres themselves are successful, may only come into existence at the cost of elbowing their neighbours out of it. So long as the material was used for its own sake, and no attempt was made to go beyond its natural limits, all went well, but as soon as the artists began to be discontented with the restrictions its use put upon their opportunities of showing their own dexterity, the lustre colour had to give way. It may have been this, or possibly the demand may have been diminished by the disappointment consequent on local mishaps. The death of a furnaceman of special skill might cause a suspension of work, or, what is more likely, a substitute might be found whose failures might lead to a belief that the process depended on some secret which his predecessor had kept to himself. Whatever the cause, or complication of causes, they vanish in 1550, and do not re-appear for 300 years.

The process is not described by Brongniart, who was the great technical authority on pottery of fifty years ago; and Salvêtat, who was his successor, makes only a very speculative allusion to its possible character. And in the catalogue of the Great Exhibition of 1851, which is a sort of death register of the arts of antiquity, not a hint of lustred pottery appears. The modern revivals begin with those at the Ginori factory at Doccia, near Florence, and those of Carocci at Gubbio,* of which Mr. Fortnum speaks very highly. There were some of these in the 1862 Exhibition in London. I have never seen any myself. The best I have seen are those of Cantagalli, at Florence.

In spite of the Doccia and Gubbio reproductions, an impression continued to prevail that the process was a secret. I used to hear it talked about among artists, about twenty-five years ago, as a sort of potters' philosopher's stone. At that date the attempts to reproduce it in England had met with only very partial success, although an Italian had gone the round of the Staffordshire potteries showing how to do it. Even now it is sometimes spoken of as a secret by newspaper writers. My attention was attracted to some very interesting work of Massier, of Cannes, in the last Paris Exhibition, by a newspaper paragraph headed "Re-discovery of a Lost Art."

In fact, re-discovery appears to have dogged the footsteps of the lustres from the beginning. I re-discovered them myself in 1874, or thereabouts, and in the course of time some of my *employés* left me, and re-discovered them again somewhere else. I do not think any re-discoveries of this sort contributed in any way to the very general diffusion of the process in

* A story is told by Marchese Brancaleone of the re-discovery at Gubbio, that an old painted unfired piece, of the Giorgio time, was found in what was supposed to be his old kiln-house. One of these fell into a scaldino, and remained in contact with the fuel. Next day it was found that a lustre had developed on it. (Brancaleone Letter to Marchese Eroli, 1857, p. 24.)

the potteries at this moment. Very likely some of them have an earlier record than mine, but the only one I chanced upon when I was in Staffordshire was that of the late Mr. Clement Wedgwood, who showed me a number of experiments which would have been successes if the glaze had been suitable, and a small sample shown me by the late Mr. Colin Campbell. As far as the technical difficulties of simply evolving a copper or silver lustre go, I see no reason why (as in the case of the Arabs and Italians) every discovery should not be totally unconnected with every other. But there was one thing the Italians found out, when they reproduced the Moorish firings, namely, how to make a strong, and beautiful, and original use of their materials. It may be that the less we say about the modern parallels of their case the better.

Perhaps we may now make a new departure, and consider that the process is as well known as any other process in the arts; at any rate, I will contribute what I can to make it so, by telling all I know of it myself. I got nothing from Piccolpasso, as I did not see the work till long after, nor from any printed information, except the chemical manuals I had read in youth. The clue was furnished by the yellow stain of silver on glass. When overfired this shows iridescence, which is often visible on the opaque yellow visible from the outside on stained glass windows. I tried the stain on Dutch tiles, and found them unsusceptible in the glass kiln, but, in a small gas muffle, I found that both copper and silver gave a lustre when the gas was damped down so as to penetrate the muffle. I pursued my investigation, and, after an interruption, occasioned by setting the house on fire and burning the roof off, I developed the process in Chelsea. This was 1873-74, since which time it has not varied materially, although I have tried many experiments, with a view to improving it.

As we now practise it at Fulham, it is as follows:—The pigment consists simply of white clay, mixed with copper scale or oxide of silver, in proportions varying according to the strength of colour we desire to get. It is painted on the already fused glaze with water, and enough gum arabic to harden it for handling and make it work easily—a little lamp black, or other colouring matter, makes it pleasanter to work with. I have tried many additions to this pigment, of infusible white earths such as lime, baryta, or strontia, and other metallic oxides, but without superseding the first simple mixture. Any infusible clay will answer the purpose, though we have always used kaolin, as the least fusible. In Deck's work on pottery he gives several receipts for lustre pigments, only one of which seems to me to belong to the true process of lustre. The others all contain sulphur, which is not necessary, though it may work very well. The sulphur lustres are akin to the old Swansea lustre, which only requires to be burnt at a low heat without smoke. The sulphur evaporates and leaves a metallic deposit which is not oxidated, or only partly so, by the access of air after the sulphur vapour has left the kiln. I believe all the lustres included in the colourmaker's lists are of this nature, but the results produced in modern ware do not tempt the investigator. The prettiest one I have seen is Burgos lustre, which, however, contains gold.* The only ingredient containing sulphur mentioned by Piccolpasso would be the small quantity of vermilion (that is, if *cinabrio* means vermilion), which he adds to his receipt for *oro*. Piccolpasso's recipes are for the diluent clay only, as he says nothing of either copper or silver. But he had them from hearsay, and if he really tried to produce lustre with them without any addition of metal, it quite accounts for no lustres ever appearing at Castel-Durante, where he was master potter. Indeed, it raises the question whether he was not hoaxed by Maestro Cencio, Giorgio's son, who is supposed to have given the information.†

The ware, when painted, is packed in a close muffle, which is then raised to a very low red heat, so low, when the ordinary tin enamels are employed, as to be only just visible. A charge of dry wood, sawdust, wood-chips, or, indeed, any combustible free from sulphur, is then introduced into the

---

* Sir R. M. Smith says the Persian glazes contain gold, but he does not give his example of a chemical analysis showing gold.

† Senor Juan De Riano gives the recipes sent to Count Florida Bianca in 1785 from Manises. The pigment contains sulphur, and no mention is made of the reduction process. This rather inclines me to believe that the potters of that date, having found that a quasi-lustre could be obtained with the sulphur material, had either neglected the reduction by smoke, or only practised it in a modified form. If we accept this recipe as a true account of the Hispano-Moresque operation, it gives an additional reason for supposing that of Piccolpasso to be an independent re-discovery. The Italian process would consist of variations throughout. Signor Cantagalli has shown me the whole process as now practised at his works, and I have no doubt it is in all respects the same as the old Italian one. Certainly his results are more like the Pesaro and Gubbio than the modern Valencia ware is like the best Hispano-Moresque.

muffle through an opening level with the floor, a space having been left clear under the ware for its reception. As soon as it has blazed well up, the opening is closed. The flare then chokes down and the combustion of the charge is retarded, the atmosphere in the muffle consisting entirely of reducing smoke. The test pieces will soon begin to show a red or yellow stain, the pigment itself looking black, until it is wiped off to show the stain. This operation must be repeated until the tests look right, when the fires should be drawn and the muffle left to cool.

The difference between this operation and Piccolpasso's is chiefly in the use of the closed muffle, which is rendered necessary by the difference in fuel. The sulphur from coal or coke would injure the glazes where there was no lustre, and would interfere with the process itself. In the Italian process, where wood is the fuel, the wood is packed in a perforated sagger, into which the smoke from the furnace is choked back by closing a damper, or by simply increasing the volume of smoke from the furnace by heaping on brushwood. But the principle of the operation is the same in both cases, and the dangers are the same. The firing may be vitiated in either by any of the following causes. There may be too great heat, or too prolonged heat; the smoke may be too dense, or too attenuated, or not long enough maintained, or the reverse. If more than one of these factors is wrong at the same time, the harm done will be in proportion. Even when the conditions are most closely observed, the results will show unexpected variations. It is impossible to secure uniformity throughout a muffle. Consequently, the size of the ware must be small in proportion to that of the muffle, or a vase might be overdone at the top and underdone at the bottom, while a number of small pots in the same space would have turned out very well, a few of the top ones being uniformly overdone (and perhaps little injured), and a few of the bottom ones underdone, and only wanting a second similar firing. This also makes a longer and slower firing necessary with larger ware, and this means more risk.

The different sorts of copper lustre may be classified thus:—

1. Opaque metallic copper deposited on the surface of the glaze. The oxide is in this case probably reduced at the moment of deposit. Nearly the same result takes place in the common lustre of the potteries, where the sulphur of the sulphide of copper is driven off by a low heat.

2. Combination of copper suboxide with the glaze without reduction to metal. This is to all intents and purposes the same thing as when glass containing copper is flashed and becomes ruby. The harder the glaze is, and the higher the temperature, the less likely is a deposit of metallic copper.

3. The result of prolonging heat without smoke on No. 1. The deposited copper is thus slowly absorbed into the glaze, becoming ultimately red without lustre, but passing through every intermediate stage.

4. The result of increasing the reducing agent on No. 2. In this case the oxide already in combination is brought back to the state of metal. I believe that all the best lustre should be classed with this or No. 3.

Silver lustres show the same results, but at a lower temperature. So when both lustres are fired together, we may expect Nos. 3 and 4 of silver lustre, with Nos. 1 and 2 of copper.

The ugliest results are when the glazes are overcharged to the point of opacity. But accidents of this sort may be taken advantage of when the designer foresees the result. For instance, great blotches of opaque pale yellow on an inky black background may be very ugly, when an arabesque of fine lines of the same yellow on the same ground might be rather pretty.

I have said that the tin glaze is the most susceptible to lustre, but it does not necessarily give the finest results. The Gubbio lustres are really on superposed marzacotto, and possibly the exceptional beauty of some Persian lustre may be due to what is often called a siliceous glaze, which is what I call an alkaline glaze, as all glazes are siliceous. A film of such a glaze over the tin would almost elude any possible means of detecting it, and yet would scarcely be penetrated by the lustre colour, so thin is it.

The best of the first lustres I made on Staffordshire ware were on ironstone or granite. The body was repellent in colour, but the glaze particularly good. Latterly, we have used the common opaque white made with tin. It has also been ugly in colour, being, I believe, made so by the addition of cobalt, to make it whiter, just as the house-painter spoils his beautiful white chalk with French blue. I have tried many experiments with glazes, but I am inclined to think that the way they are fired in the glost oven has as much to do with

their adaptability for lustre as their chemical composition.

I have also tried in this past 20 years a vast number of experiments, with the idea of adding to the first simple process of the Arabs. To save others needless work, I will enumerate a few, with my recollection of their results.

1. Reduction by other agents than carbonaceous smoke: by ammonia, by steam in contact with reducing fuel, by coal-gas, by vapour of water and glycerine or spirit. None of these gave any new results.

2. The use of copper and silver colours as enamels, or under glaze, and their subsequent reduction by any of these agents. Sometimes there were good results, but the colour was always patchy.

3. The deposit of copper or silver from vapour of the chlorides, ammonium chlorides, or iodides, those portions of the glaze being protected which were to remain white. These experiments might be repeated with advantage. A similar one was the painting of the pattern in a susceptible glaze on a refractory one, and its exposure to vapour containing copper or silver. The suboxide of copper itself vaporises under certain conditions, which is the cause of the flown red colour occurring on many examples.

I have, of course, tried endless modifications of the ordinary process, such as using special woods for smoking, sawdust, shavings, paraffin, and other combustibles. Any of these answer the purpose, the application being slightly varied. But nothing material has come of any of these experiments, and the process remains substantially the same as at first. I believe that if there had been any new opening for the application of chemistry, although I might not have followed the clue successfully, I could hardly have missed it altogether.

In conclusion, I may say that I believe we have learned all there is to know of the chemical and mechanical side of the art, as it was known to the ancients. What remains to be discovered in order to produce original work, equal to that of the Renaissance, is not a technical mystery, but the secret of the spirit which animated the 15th century not only in Italy, but all through Europe. We have got the materials and many more, but the same causes that forbid the attainment of new beauty with the new ones, have stood between us and the revival of old beauty with the old. In saying this, I do not suppose myself to be going outside a universally accepted truth, or, at any rate, one that is very rarely questioned. Some day there may be a new imagery and a new art. In the meanwhile I can only say that if anyone sees his way to using the materials to good purpose, my experience, which I regard as an entirely chemical and mechanical one, is quite at his disposal.

DISCUSSION.

Mr. H. LONGDEN said he had no technical knowledge of this subject, but he had been in the habit of using Mr. De Morgan's lustre ware, and had sometimes told people that some day they would be very glad to buy it at high prices, because it would no longer be made, though it was now not rated so highly. It was principally red lustre, and he understood from Mr. De Morgan that there were difficulties with other colours; but he had seen some silver lustre, and had hoped that the pale green colour seen in the Italian ware might have been produced. There were two plates shown, about which he hoped they would hear something more; with a deep blue ground and a red lustre on a raised ornament. He once asked Mr. De Morgan to make some lustre tiles with a raised ornament on them, but difficulties occurred and they were not carried out. They owed a great debt to Mr. De Morgan for having produced this extremely beautiful work; the metallic quality seemed to him to be very wonderful. He remembered when a boy going to the Potteries and seeing work done very much like the Swansea lustre, which he was told was done with coal tar, but it soon rubbed off. This lustre, however, did not wear off, for he knew instances in which it had been in use for twelve years, and it remained as fine as at first. If anyone saw a fireplace lined with these tiles and the fire glowing upon them, they would appreciate the value of this work.

Mr. SPARKES said all would agree that they owed a great debt to Mr. De Morgan for the re-introduction of this beautiful ware. From his point of view, it was in all respects original, because the tint he produced was not similar to those on the old Hispano-Moorish ware. He should like to know if the difference between these strong copper colours and those of more delicate Hispano-Moorish tones was due to the copper, or to the smoke treatment, or whether anything was due to the tradition that the Eastern potters used southernwood as their smoke material. The subject was really so little known amongst potters, that criticism was not likely to produce much result. The trade was taking up the matter to some extent, and he had seen some fairly beautiful things produced by Mr. Maw, but not, in his opinion, equal in artistic beauty to those of Mr. De Morgan.

Mr. DE MORGAN said there was not such a very marked difference between all the Hispano-Moorish

specimens and those now shown. There was a great difference between the Swansea lustre, which was distinctly brown, and the Spanish, a piece of which was on the table; he did not know whether it was old, but the art there was so traditional, that it would fairly represent it; it looked quite a brilliant red by the side of the brown Swansea, but it also looked comparatively brown against one of his own, which had a crimson tinge. That was due to the thickness of the glaze, which had absorbed some oxide of copper. He believed the old processes were very quick, as the Italian process now was; not more than half the length of his own. His kilns were often fired for eight or ten hours, and he should think six hours would be a long firing in the old process. That made a difference in the suboxide of copper, which soaked into the glaze and produced the red colour, while still showing a metallic reflet. That really gave the most beautiful of the ruby lustres, which could be seen particularly in the Gubbio work. The Maestro Giorgio red was a deep transparent crimson, which did not interfere with the painting under the glaze. This could be seen in some of the specimens at South Kensington; it was like running a transparent crimson glaze over a monochrome drawing. He believed that was the main cause of the difference in colour. With respect to the use of southernwood, or rosemary, or any special fuel to produce the smoke, he did not think it could make any great difference. It depended far more on the speed with which it was administered, on the density of the smoke, and the degree of heat. All carbonaceous smoke, after all, consisted of the same ingredients chemically.

Mr. HUGH STANNUS said he knew nothing practically of this subject, but he must express his gratitude to Mr. De Morgan for the very interesting paper he had read. He had always thought that the reason this craft had died out was that the recipes had been forgotten. The advocates of Patent-laws said that, when an invention could be patented, the world got the benefit of it, but before that time, the inventor kept it as a secret for his own benefit and that of his family, and thus the knowledge of it might die out. But Mr. De Morgan had given another reason, and a very pregnant one, to all handicraftsmen. He had said that the use of lustre might have died, because it was difficult to combine it with the other colours; and that was probably the true reason why it was abandoned. He noticed that Mr. De Morgan distinguished between the old lustre, which was transparent, and that which is now produced, which is opaque, and would like to know if he ever made any which was transparent.

Mr. DE MORGAN said he could find one or two specimens which had a certain amount of transparency, and would probably allow a painting to show through. The most opaque were those on the top of an opaque tin enamel, and the most transparent on a thick transparent glaze.

Mr. STANNUS asked if he had made any attempts to paint a subject in ordinary colours, and then put a lustre on them afterwards. If that could be done, and the lustre were fairly transparent, it would lend additional value to the work. In conclusion, he felt that Mr. De Morgan was a perfect artist in this handicraft. He had made sacrifices of money, time, and even health, in its pursuit. He had told them of his failures as well of his successes; and often these were more instructive. This paper, when printed, would be exceedingly valuable, and would no doubt form an epoch in the art, like the treatises of Theophilus and Piccolpassi, from which new departures might be made.

Mr. FORBES ROBERTSON said Mr. De Morgan was an example such as one rarely met with, of a combination of artistic training and a scientific habit of mind; it was for lack of artistic training that our craftsmen in the applied arts had hitherto, in a great measure, failed to produce the artistic results which were so much to be desired. He did not think there were any chemical secrets known to the antique world which were not known, or on the point of being known, though we were not, perhaps, yet educated up to the same high sense of form as existed at the period referred to, viz., the half century in which the Renaissance found its zenith. He could not go into any of the technicalities of the subject, but desired to thank the reader of the paper for what he had put before them. He had devoted a lifetime to the subject; he was, in a measure, a born, as well as a trained, artist, and he inherited that scientific habit of mind which had served him so well. He could have wished that the paper had dealt somewhat with the correlated arts, and the political and international relations of the various States of Italy at that time with Spain, the Low Countries, and Germany. Mr. Stannus had touched on an important point when he said that perhaps one of the reasons for the decay in the manufacture of lustre ware was that certain secrets were in the keeping of certain families. They knew that in many of the arts in Italy there were branches which did die out with certain families, but in most cases, even including Venetian glass, they had been restored in our own time. Another reason might have been the political changes gradually going on in the Italian States of that day. The commerce of those great cities that brought about the revival of art, letters, and everything else was on the decline; the Portuguese and Spaniards were coming to the front, and it was in vain that the Venetians offered any money if the Portuguese discoverers would only let them act as their factors and agents for the sale of eastern commodities, especially spices, which up to that time had been in their hands. But the moment Vasco di Gama doubled the Cape the prosperity of Italy declined, and with it the arts also. However,

Mr. De Morgan might be assured that he had devoted himself to the most enduring of all the arts. Everything done by the hand of man in stone or metal would one day disappear, but thousands of years hence his little articles of pottery, however fragmentary, would remain. When all the other things which marked the state of civilisation at any particular period had gone, and when the names of all our living academicians were forgotten, bits of Mr. De Morgan's pottery would be found, and his name would be mentioned with respect.

Mr. TRICE MARTIN said he had had the pleasure of knowing Mr. De Morgan from boyhood, and remembered even his early attempts at art when at school. To illustrate the connection between the arts of Italy and the East, he might mention that he recently saw a pair of heavy Moorish stirrups, evidently made in the East. The shape was Eastern, the rough outer decoration and the inlaid work were Eastern, but outside they were covered with an excellent Italian enamel. They were apparently of 14th century workmanship.

Mr. PHENE SPIERS said he had had the pleasure of knowing Mr. De Morgan a great many years, and it was very seldom one met with such a combination of qualities — with scientific training, artistic perception, and a vivid imagination, all of which were apparent in his productions. It was interesting to notice how the scientific side of his character gave him such a mastery of the technical part of the process: whilst his artistic powers gave beauty to the objects produced. It was very fortunate for this branch of art that it was taken up by a man of so many sided a nature.

The CHAIRMAN, in proposing a vote of thanks to Mr. De Morgan, said he was not competent to deal with any of the technical questions raised in the deeply interesting paper they had just heard read, but, from his knowledge of the Indian potters' methods, he was of opinion that sufficient importance was not attached in England to the kind of fuel used in firing glazed ware, and that it was too severely scientific a dictum to say, as Mr. De Morgan did:—"Smoke is Smoke." In India—that is, more particularly in Scinde and the Punjaub—the utmost importance was attached to the influence of fuel in determining the tone, and even the tint of the colours to be developed; and as to whether, at a certain point, the flame of the fire should predominate or its smother of smoke. Of course, in India everything done was of religious prescription, and we had always to allow for that; but, at the same time, one generally discovered, even in the obscurest industrial processes followed by the Hindoos, that the religious prescription was based on immemorial experience of the technical results obtained. In a paper read by him many years ago in that place on "The Indian Potter," he gave a number of the recipes employed in the production of the glazed wares of Scinde, the Punjaub, and Madras, pointing out that while they never failed in developing the exact tone of colour required, the potters themselves attributed this entirely to the fuel in the furnace, whether of this or that wood, or goats' or other dung. As to the Spanish word, *azulejo*, "a tile," undoubtedly it originally meant a "blue-tile" [quasi azul-teja (compare Latin tegula, tegmen, tectum, and Tamil *tekka*, the *Tectona grandis*)]. In Minsheu [1599], the entry is "Azulejo, *a painted* tile, or *paving bricke, that is, of divers colours, blew clour;*" and azure itself is derived through the Low Latin *lazur*, and Low Greek *lazoúrion*, from the Arabic *lajwardi*, that is "lapis-lazuli," the blue stone from the Lajwurd mines in Badakshan, on the north-west frontier of India, whence comes also the Balas ruby; and *lajwurdee* is the name still sometimes given in north-west India to the turquoise blue tiles of Scinde and the Punjaub, and it is the origin of the frequent Anglo-Indian error of the colour of these tiles being prepared from "lapis lazuli." With regard to the question of the historical genesis of lustre ware, he believed it was far more ancient than the Saracens. The Saracens originated nothing in art, and it was time that people gave up all idea of there being any such thing as Saracenic or Arab art; and then many difficulties in connection with the history of the decorative arts would at once disappear. Delighting as they all did in sumptuary splendour, none of the Semitic races had ever shown any genius for the decorative arts. It should be remembered that at the time when Christianity began to gather force in Anterior Asia, and just before the irruption of the barbarians into the Western Roman Empire, the Greeks were rapidly discovering all the scientific secrets, the possession of which is the boast of modern civilisation. But just ere it reached the zenith of its evolution, ancient civilisation was overthrown at a blow by the Christianised Cæsars of Byzantium closing the schools of Greek philosophy at Athens, and of Greek science at Alexandria; and the rise of the Papal power at Rome on the ruins of the Western Empire, completed the catastrophe which involved Western Europe in the darkness of the Middle Ages for a thousand years. The Eastern Empire preserved its organisation for some time longer, and when at last despoiled of Syria and Egypt by the Saracens, Greek culture still retained sufficient vitality in Anterior, and, indeed, through the Nestorians, in Central Asia, to influence the wild Arab conquerors of those countries, not only in their arts and sciences, but in their political administration. The Arabs held their conquests in Africa and Syria, indeed only so long as the Greek principles of Government were followed by them. It was in a similar way that they entered into the inheritance of Greek science and Greek (Byzantine or Orientalised Greek) art, and thus preserved the traditions of both in Southern Europe, all through the night of the Dark

Ages. But they were nothing more than the diffusers of the science and art received by them from the Greeks, just as the Phœnicians had been the intermediaries before them in the propagation of Egyptian art among the natives of the Eastern basin, and of Greek art among those of the Western basin of the Mediterranean. There is no Arab art, not even in Arabia, and, to this day, all the arabesque embroidery of Egypt and Syria is done by Greek tailors. In conclusion, Sir George observed that it was a matter of the liveliest gratification to them all to have heard from the re-discoverer in this country of the lost art of lustre ware so full and unreserved an account of it; and, in reading his interesting paper on it, Mr. De Morgan had brought to a brilliant conclusion the Session of the Applied Art Section of the Society, so successfully opened last January by Mr. William Morris with his paper on "The Illustration of Gothic Books." He felt most grateful to Mr. De Morgan, and he begged to thank him most sincerely, not only on his own account, and for all present, but on behalf also of the Applied Art Section of the Society of Arts.

The vote of thanks having been carried unanimously,

Mr. DE MORGAN, in reply, said there was one point in which, to some extent, the paper might seem to be at variance with the remarks of the Chairman; but he wished it to be understood that, when he identified the era of Arab conquest with the extension of this particular secret, he was not committing himself to an opinion as to whether the Arabs were or were not artists. Only this particular thing somehow or other happened, that as they spread over Europe—or, rather, a certain length of time after—curiously enough these things appeared. There was a good deal to be said for the view that, even in Spain, the work was done by Persians. Señor Riaño mentioned that there was a colony of Persians in Andalusia, that Xeres was really Shiraz, and other things of the same sort, all pointing to the fact that the great promoters of the art were Aryans, and not Semites. Nevertheless, it was a curious coincidence that this particular form of art was always associated—at least, as to locality—with the Arab conquests. He concluded by describing the characteristics of several of the specimens exhibited.

Miscellaneous.

THE INDUSTRIES OF FINLAND.

M. Maurice Harbulot, writing in the *Monde Economique*, says that the most important industry of Finland—from the point of view of the value of the production—is that of wood-sawing by machinery. There are 253 important saw mills, employing 8,024 workpeople, and with a production valued at about £1,100,000. Eighteen of these establishments are situated in the towns, and the remainder in the rural districts. The cotton industry occupies the second place. This produces annually nearly £500,000, and is centralised in the hands of six proprietors. In the towns there are four cotton manufactories, employing 2,535 hands, and in the rural districts two establishments only, employing 1,174 workpeople. The following, in the order of their importance, come after the two chief industries. Wood polishing, manufacture of wood pulp, cellulox, and paper. Of these there are 28 establishments, employing 2,615 workpeople; value of the production, £420,000. Tanneries and leather factories number 602, and employ 1,903 workpeople. There are 35 foundries and establishments for making machinery; 84 breweries, 31 tobacco factories, 2 sugar refineries, 199 dairies, 1,350 mills, 1 linen factory, 32 brandy distilleries, &c. The total value of the industrial production of Finland was, in the latest year for which particulars are available, £4,933,000. At this period there were 6,018 industrial establishments, of which 3,005 were in the towns and 3,013 in the country districts. The number of workpeople engaged in the various industries was 45,335, of which 23,867 were employed in the towns and 21,468 in the country. On the 31st December, 1888, the population of the Grand Duchy amounted to 2,305,916, and there were, therefore, 19 persons engaged in the various industries of the country to every 1,000 inhabitants.

Correspondence.

THE EXTENSION OF COLONIAL TRADE.

The contribution of Mr. J. R. Carter, F.S.S., to the discussion on the paper read by Colonel Howard Vincent, is misleading in the following particular. He gives the value per head of exports of British produce from the United Kingdom in 1890 at £7 0s. 8d., and says that this amount per head is greater than at any previous time. This is true, if the term "any previous time" include only 1876 and the subsequent years, but it is incorrect if applied to the years 1872, 1873, and 1874. Taking the average of the five years, 1870-4, the value per head of exports of British produce is given in the Comparative Trade Statistics for 1854-90 as £7 7s. 3d. Again, in the Table at the end of his statement, Mr. Carter commences his statistics at the year 1876. If he had included the statistics for years 1870-74, they would have told a very different tale. The value of our average export of British produce to the United States in these five years was £33,000,000 sterling, whereas in 1890 the value was only £32,000,000 sterling. In 1872 our export of

British produce to the United States was valued at £41,000,000 sterling, the highest point it has yet reached. In the same year the value of our export of British produce to British North America was £10,000,000 sterling, and to Australia and New Zealand £14,000,000 sterling.

HOLT S. HALLETT.

It may be useful to offer some explanations of the important subject introduced to the Colonial Section by Colonel Howard Vincent.

One cause of conflict among the speakers was what is called "free trade," and the assumption that the great expansion of the industry and commerce of this country within the last forty years is due solely to "free trade."

Undoubtedly, as a doctrine of economic science, there can be no doubt that free trade, where there is free trade, must tend to promote commerce. Even the limited free trade or relaxation of fiscal regulations, which we have enjoyed for some years, must have been beneficial so far as it goes. This, however, is a very different thing from the assertion that the vast expansion of our industry and the increase in totals of values is to be assigned to "free trade."

This expansion is to be recognised, more or less, not only in this country, but in all the countries of the world, and that whether they have been under "free trade" or protection.

If an economist, like Mr. Bourne, sits down to write the history of the last half century, he must account not only for "free trade," but for the coincident circumstances. He must enumerate amongst others—

The gold discoveries.

The opening of the Pacific world to trade.

The advance in prices in India, China, Japan, &c.

The inventions of English speaking men on both sides of the Atlantic, of Bessemer, Siemens, &c., affecting productions and affecting prices.

The extension of railway and steamboat systems in all the countries of Europe and America.

The volume of produce has been increased and prices have been reduced, and by the energy of our people chiefly, these results have been produced in every region.

Sir Robert Peel and Mr. Cobden did not foretell the discoveries of gold in California, Australia, and South Africa (nor, it may be said, of silver), and to these rather than to the effect of "free trade" are large results to be attributed.

The trade to the Pacific countries alone now constitutes a great volume, and in this France, Germany, the United States, Holland, &c., largely share; and this, of course, is independent of "free trade" to them.

It is to those inventors who have been rewarded by our Society with the Albert Medal that the greatest economical operations are to be assigned and it is almost needless to point out that Sir H. Bessemer and the others were in no degree associated with the initiation of "free trade," though to them we owe the development of industry and commerce here, and in the United States, and on the Continent of Europe.

From the discussion now set on foot, we may eliminate "free trade" as a main cause, while recognising to the full, as a matter of economical doctrine, that free trade, if applied, is a valuable auxiliary of commerce.

There will also have to be considered how far the doctrines of economical science are to predominate, and how far the doctrines of another important science—that of political science—are to be applied. It may happen, after careful discussion, that there can be no demur to the theoretical acknowledgment of free trade, on one side, and no political or practical objection to the application of the measures advocated by Colonel Vincent, and those who gave him more or less support.

HYDE CLARKE.

32, St. George's-square, S.W.,
20th June, 1892.

General Notes.

NATIVE PASSENGER SHIPS IN INDIA.—According to a return recently issued by the Indian Government, the total number of people who sailed from Indian ports in native passenger ships, that is, sailed as passengers, being neither emigrants to the colonies nor pilgrims to the holy places in Arabia, was 1,001,892 in 1888-89, 1,081,403 in 1889-90, and 1,170,565 in 1890-91. The great bulk of these voyaged only within Indian limits, not more than 71,782 leaving India in the past year. Of those who left India, about three-fourths went from Madras Presidency to the Straits Settlements (18,804) and to Ceylon (36,586), most of the remainder going from Bombay and Karachi to the Persian Gulf (10,343), Mauritius, Zanzibar, Aden, and Trieste. The large number (1,098,783) who voyaged within Indian limits confined their migrations in the main to ports within their own Presidency, only 206,560 out of the whole number leaving their own Presidency or province to seek for work in other provinces. These migrations from province to province are practically limited to voyages undertaken by coolies from Madras and Bengal to Burma, and to the return voyages of coolies from Burma to their own provinces.—*Board of Trade Journal.*

Notices.

NEW VICE-PRESIDENTS.

At a meeting held on Wednesday, June 29, after the Annual General Meeting, the Council elected (in accordance with the Bye-law passed at a General Meeting held on Wednesday, 18th May) the following gentlemen as Vice-Presidents of the Society:—The Attorney-General, Q C., M.P., for the years 1892 93 1893-94; Sir Philip Cunliffe-Owen, K.C B., K.C M.G., R. Brudenell Carter, F.R.C.S., Sir Edward James Harland, Bart., M.P., and John O'Connor, M.P., for the year 1892-93.

The terms of the Bye-law passed at the General Meeting held on Wednesday, 18th, are as follows:—"That in accordance with the proposal from the Council, the Bye-laws be altered and varied in such manner that the Council shall be empowered, during the years 1892 and 1893, to appoint not more than six members to be Vice-Presidents or other Members of the Council, in addition to those appointed under Bye-laws 79 and 84, and that the Council be empowered to determine the period or respective periods that members so appointed shall continue in office, not being later than the end of the Session commencing 1893, and that all Bye-laws which are inconsistent with such appointment and determination be suspended or varied."

CHAIRMANSHIP OF COUNCIL.

On Wednesday, 29th June, at their meeting, held after the annual election, the Council elected Sir Richard Webster, Attorney-General, Q.C., as Chairman, and Sir Frederick Bramwell, Bart., D.C.L, F.R.S., as Deputy-Chairman, for the ensuing year.

The various Committees were also re-appointed.

CONVERSAZIONE.

The Society's annual *Conversazione* was held at the South Kensington Museum (by permission of the Lords of the Committee of Council on Education), on Wednesday evening, 29th June. The courts and galleries of the ground floors, and the galleries containing the Raphael cartoons, the Sheepshanks collection, the William Smith collection of water-colour drawings, the Dyce and Forster pictures, and the Chantrey bequest were open.

The company were received in the South Court by Sir Philip Cunliffe-Owen, K.C.B., K.C.M.G., C.I.E., and the following Vice-Presidents and Members of Council:—Major-General Sir Owen Tudor Burne, K.C.S.I., C.I.E.; Alfred Carpmael; Michael Carteighe; Sir George Hayter Chubb; Major-General J. F. D. Donnelly, C.B.; Sir Henry Doulton; Professor Francis Elgar, LL.D.; C. Malcolm Kennedy, C.B.; Alexander B. W. Kennedy, F.R.S.; Sir Villiers Lister, K.C.M.G.; J. Biddulph Martin; Sir Owen Roberts, M.A., D.C.L., F.S.A.

Promenade Concerts were given by the Band of the Royal Engineers (conductor, Mr. Joseph Sommer), in the North Court, and by the Band of the Scots Guards (conductor, Mr. Edward Holland), in the Quadrangle of the Museum.

A Vocal and Instrumental Concert, by the Meister Glee Singers and the Meistersingers' Orchestra, was given in the Lecture Theatre under the direction of Mr. Norfolk Megone.

The number of visitors attending the *Conversazione* was 1,750.

Chicago Exhibition, 1893.

MEETING OF THE ROYAL COMMISSION.

A meeting of the Royal Commission was held on Wednesday, 29th June. Present: Sir Frederick Bramwell, Bart., D.C.L., F.R S., in the chair; Sir Frederick Abel, K.C.B., D.C.L., D.Sc., F.R.S., the Duke of Abercorn, C.B., Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., Major-General Sir Owen Tudor Burne, K.C.S.I., C.I.E., Michael Carteighe, Sir Philip Cunliffe-Owen, K.C.B., K.C.M.G., C.I.E., Sir Henry Doulton, James Dredge, Francis Elgar, LL.D., Sir Douglas Galton,

K.C.B., D.C.L., F.R.S., Thomas Hawksley, F.R.S., Charles Malcolm Kennedy, C.B., John Biddulph Martin, George Matthey, F.R.S., and Sir Owen Roberts, M.A., F.S.A.

EXECUTIVE COMMITTEE.

A meeting of the Executive Committee was held on Wednesday, 29th June. Present: Sir Frederick Bramwell, Bart., D.C.L., F.R.S., in the chair; Sir Frederick Abel, K.C.B., F.R.S., Sir Philip Cunliffe-Owen, K.C B., K.C.M.G., James Dredge, Sir Douglas Galton, K.C.B., F.R.S., George Matthey, F.R.S.

TRANSPORTATION COMMITTEE.

A meeting of the Transportation Committee was held on Thursday, 23rd June. Present: Francis Elgar, LL.D., in the chair; B. Francis Cobb, James Dredge, William Forbes, J. F. S. Gooday, Walter H. Harris, Charles Holmes, Pres. Inst. Brit. Carriage Manufacturers, George Norgate Hooper, Colonel Sir Nigel Kingscote, K.C.B., M.P.

DEPARTMENT OF ELECTRICITY.

The following circular to Exhibitors, from Mr. J. P. Barrett, Chief of the Electricity Department, has been received:—

It is the purpose of the Exposition management to allow exhibitors to completely equip the Electrical Building for lighting and power. With a view to determine just what may be done in this direction, the Department of Electricity chooses to place its plans before those who are interested in its success, and advise with them as nearly as may be, with a view to give them an opportunity to participate in this equipment.

Under the rules of the Exposition it will be necessary to plant all operating machinery in what is to be known as the general power plant in Machinery Hall, 700 feet from the Electrical Building. All generators will be established at that point immediately adjacent to steam power of competent capacity. Between this power plant and the Electrical Building there is a subway six feet deep and six feet wide, for the accommodation of conductors. Fire-proof vaults will be built at the point of entrance to the Electrical Building in which to instal transformers, to comply with the National Underwriters' requirements. Headway averaging 7 feet under the flooring, and foundation posts at intervals of 12 feet, will give ample wiring facilities.

It is the purpose to divide the building into equitable sections, and to assign these sections to the various exhibiting interests. Those to whom assignments are made will be expected to instal their own generators, furnish cables between the plant and the building, and do all wiring, including the furnishing of wire. Those who are given arc lighting to do will be expected to furnish carbons, and attend to renewing same. Those undertaking to operate incandescent lamps will be expected to furnish all renewals and attendance. In addition to these items of expenditure, all exhibitors whose generators are operated from steam in the power-station will be asked to pay, *pro rata*, the costs incident to the erection of the machinery. Belting, from shafting to generators, must also be furnished by exhibitors: and exhibitors of alternating systems will be asked to contribute to the expense of constructing the transformer vault.

The building will be equipped for 500 horse-power for the operation of motors, 500 horse-power for arc lights, 500 horse-power for incandescents, and a reserve of 500 horse-power for extra incandescents, applications for most of which are already in.

In order that the plant for this building may not be a source of expense to the Exposition management, a charge will be made for any special arc lighting desired by exhibitors who do not participate in the equipment and electrical supply of the building, also against the same class of exhibitors who desire power for motors or who require incandescent lamps. These charges do not concern any who contribute to the expenses cited above.

In order that the above proposed system may be reduced to a definable quantity, I beg leave to submit the enclosed blank, which please fill out completely, and return to me at once.—Very respectfully,

J. P. Barrett,
Chief of Department.

Copies of the form can be obtained on application to the Secretary to the Royal Commission.

Proceedings of the Society.

ANNUAL GENERAL MEETING.

The Annual General Meeting, for receiving the report from the Council, and the Treasurers' Statements of Receipts, Payments, and Expenditure during the past year, and also for the Election of Officers, was held, in accordance with the Bye-laws, on Wednesday last, the 29th June, at four p.m., Sir Frederick Bramwell, Bart., D.C.L., F.R.S., Deputy-Chairman of the Council, in the chair.

The Assistant-Secretary read the notice convening the meeting, and the minutes.

The CHAIRMAN read the following letter, written by the Secretary to the Chairman of the Council, Sir Richard Webster, who was unavoidably prevented from presiding at the meeting :—

June 14, 1892.

DEAR SIR RICHARD,—May I ask you to express to the meeting my extreme regret at my enforced absence. I am sure the meeting will understand that I am doing more useful work for the Society in America than I could do by remaining in England, and they will therefore excuse my absence from so important a part of my duty as attendance at the Annual General Meeting.

Yours faithfully,

H. T. WOOD, *Secretary*.

The Attorney-General, M.P.

The following candidates were proposed, ballotted for, and duly elected members of the Society :—

Benson, George Henry, Holly-lodge, St. Saviour's, Jersey.
Blott, Walter, Manningdale, South Norwood, S.E.
Brooke, Wilton, Ashville, Stairfoot, near Barnsley.
Broomhead-Colton-Fox, Barnard Platts, Wales, Kiveton-park, Yorks.
Cassavetti, John, The Cedars, Torquay, and Exeter College, Oxford.
Chaney, Henry James, 7, Old-palace-yard, Westminster, S.W.
Corsan, John Richard, 58A, Gray's-inn-road, W.C.
Elliot, John, Derwent-house, Upper Villiers-street, Wolverhampton.
Ellwood, Thomas Ashcroft, 13, Cavendish-road, Harringay, N.
Farquharson, Lieut.-Colonel J., R.E., Ordnance Survey-office, Southampton.
Foster, Charles Rolls, 54, Pall-mall, S.W.
Fry, Joseph, 48, Royal Exchange, Manchester.
Gaze, Harry E., Oakhurst, Ravenscourt-square, Hammersmith, W.
Harland, Sir Edward James, Bart., Baroda-house, Kensington-palace-gardens, W., and Glenfarne-hall, Enniskillen, Ireland.
Jones, John, 40, Sydney-street, S.W.
Ketchley, Rev. H. E., B.A., Devon-lodge, Malvern.
Little, Thomas David, Public Works Department, Bombay, India.
Logan, David, care of Henry S. King and Co., 65, Cornhill, E.C.
Loyd, William Graham, 122, Cannon-street, E.C.
Lyon, John George, Knottingley, Yorks.
Marshall, William Bayley, Richmond-hill, Birmingham.
Mason, Francis Herbert, 9, Pall-mall, S.W.
Minty Samuel, The Triangle, Bournemouth, Hants.
Munro, Hon. James, Grand Hotel, Charing-cross, S.W.
Shackleford, Arthur Lewis, 223, Bristol-road, Birmingham.
Shaw, William Thomas, 110, Bunhill-row, E.C.
Skinner, Arthur B., B.A., 2, The Residences, South Kensington Museum, S.W.
Tattersall, William, 90, Arden-terrace, Accrington, Lancashire.
Taylor, John, 15, Lucius-street, Torquay.
Wansbrough, Cecil Shartman, Arlington-villa, Barrow-in-Furness.
White, Henry, 80, London-road, Carlisle.
Wurtzburg, John Henry, care of Greenwood and Batley, Albion Works, Leeds, and 2, De Grey-road, Leeds.

The CHAIRMAN nominated Mr. Wyatt Papworth and Mr. John Jewell Vezey scrutineers, and declared the ballot open.

The ASSISTANT-SECRETARY then read the following

REPORT OF THE COUNCIL.

I.—ORDINARY MEETINGS.

The Session commenced, as usual, with an address by the Chairman of the Council. The principal subject dealt with in his address by the Attorney-General was the connection of the Society of Arts with Exhibitions in the past, and its special association in the future with the Exhibition at Chicago, and he concluded by impressing on his audience the importance of this country taking an adequate part in the Columbian Exposition of 1893.

The same subject was treated in a paper a few weeks later by Mr. James Dredge; this paper contains the fullest account which has yet appeared on the scope and organisation of the Exhibition. The same subject lent a special interest to a paper read in the latter part of the Session by Mr. Robert S. McCormick, the resident Commissioner for Great Britain of the World's Columbian Exposition, on "The Future Trade Relations between this Country and America." Mr. McCormick pointed out that the United States were now pressing Great Britain hard in many markets of the world, and that they were likely to urge their claims still more vigorously in the future. He also showed that the growth of manufactures in the States was working a revolution in the trade between this country and America, and pointed out the advantages to be gained for our industries by a good representation in the British Section at Chicago. The subject of our trade relations with foreign countries was also dealt with by Mr. Ewing Matheson in a popular manner in his paper on "Foreign Exchanges."

At the first meeting after the opening address, Professor Silvanus P. Thompson, to whom the Society is indebted for many important contributions in the form of lectures and other communications, read an interesting and important paper on the measurement of lenses, and described the apparatus he has devised for the purpose. Other papers dealing with optical subjects were those by Dr. Edridge-Green, on "Lovibond's Tintometer," and by Capt. Abney, on "Colour Blindness." A domestic bereavement rendered it impossible for Capt. Abney himself to read his paper, but the Society is much indebted to his colleague at South Kensington, General Festing, for not only reading the paper, but also for supervising the conduct of the very beautiful experiments illustrating the results of Capt. Abney's recent work with which General Festing had been intimately associated. With these papers should be mentioned the one contributed by Mr. Ives, the distinguished American student of photographic chemistry. In it was described the very beautiful device by which the author has succeeded in reproducing to the eye the actual colours of the object photographed, either on a screen or in an apparatus as portable as an ordinary spectroscope. It is to be remembered that Mr. Ives's invention has nothing in common with the many attempts to produce photographs in colour by chemical means.

Electricity has not taken so prominent a place among the subjects dealt with before the Society at the ordinary meetings as in some recent years, but there were two papers coming under this head, one by Mr. G. H. Robertson, on "Secondary Batteries," giving the results of much valuable and original work, and one by Mr. J. N. Shoolbred, describing the successful arrangements which have been made by the Bradford Corporation for the supply of electricity to that town.

Mr. A. P. Laurie, whose lectures on the "Pigments and Vehicles of the old Masters," referred to in a later part of this report, gave in his paper on the "Durability of Modern Pigments," the results of some further experiments he has been carrying on since the date of his paper read before the Society on the 8th April, 1891. Another paper dealing with matters of an artistic nature was that of Mr. Ernest Hart, on "Ancient and Modern Art Pottery of Japan," a subject on which he is one of our leading authorities.

Two papers may be classed as dealing with geographical topics; in one Capt. Younghusband gave an account of his recent enterprising and important explorations in the Pamirs; in the other, Dr. Tempest Anderson described the less distant and more familiar districts of Iceland which he had lately visited.

Egyptian agriculture formed the subject of an important paper by Professor Wallace, which had to be read in the absence of the author on account of his sudden illness. Prof. Vivian B. Lewes, in his paper on the "Spontaneous Ignition of Coal," carried on further the subject which he brought before the British Association, at its meeting last autumn, and made numerous practical suggestions with reference to the sea carriage of coal. Mr. Price-Edwards, whose paper on "Experiments with Lighthouse Illuminants at the South Foreland" (read before the Society on the 10th March, 1886) will be in the memory of those interested in lighthouse matters, supplemented it this Session with a paper on "Burning Oils for Lighthouses and Lightships."

General Pitt Rivers gave an account of the system he has elaborated for the arrangement of Museums, a subject with which the Society has long been associated, and in which its members take great interest. Mr. T. Pridgin Teale's paper on "Dust" was of practical value, and was the only one treating of a sanitary question read during the Session. Mr. Addenbrooke, in his communication on the "Uses and Applications of Aluminium," showed how rapidly the reduction in price of this remarkable metal is extending its useful applications. Mr. Gilbert R. Redgrave, in his paper on the "Manufacture and Industrial Application of Flexible Tubing," gave an account of the very ingenious method by which a coiled metal tube is made at once quite flexible and perfectly water-tight.

II.—INDIAN SECTION.

Seven meetings in all have been held. The Session opened on January 21st, when Mr. Herbert Jones, a young traveller of ability and promise, described to a large audience an interesting journey made by him on the Russo-Chinese frontier, from Tien-Shan to the Pamirs. A feature of the discussion was the manner in which Mr. Jones's sympathetic references to Russia's colonising work were endorsed by most of the speakers, including the well-known Asiatic traveller, the Rev. Dr. Lansdell, and the distinguished Anglo-Indian Chairman, Sir W. W. Hunter. To geographers this

paper was of special interest, Mr. Jones having been the first Englishman, as Dr. Lansdell pointed out, to cross the Tien-Shan mountains from Viernay to Kashgar. The second meeting took place on February 11th, when Lord Lamington delivered to a crowded assembly a graphic account of his not unadventurous wanderings in the Northern Shan States, a part of the world that has come more prominently into public notice since our annexation of Upper Burma. Amongst those who took part in the discussion were Sir Steuart Colvin Bayley, and Sir Charles Crosthwaite, whose remarks on the opening up of the country by railways were of value, as proceeding from an official of his experience. On March 3, Surgeon Major-General Sir William Moore, honorary physician to Her Majesty, contributed a useful paper on "Indian Sanitation and the International Congress of Hygiene." His paper may be commended to the notice of those foreign hygienists who are constantly heaping abuse on India as the "origin and home of cholera." "What has been done," said Sir W. Moore, "is not brought out sufficiently prominently, and I look forward to its being demonstrated at future Congresses that India is not so much behind in sanitation as is generally believed." In the meantime it may be hoped that Sir W. Moore's own paper will help to dispel some of the erroneous notions to which he referred. Major-General Sir Owen Burne presided, and, together with Sir Douglas Galton (chairman of the Organising Committee of the Seventh International Congress of Hygiene and Demography), Surgeon Lieut.-Colonel Hendley, and others, took part in an instructive discussion. On March 24, a spirited defence of the opium trade was made by Mr. G. H. M. Batten, formerly of the Indian Civil Service, and the discussion which followed the reading of a very instructive paper is generally admitted to have been the most important that has ever taken place on this much-debated question. Sir Thomas Wade, Mr. Horatio Nelson Lay, and Sir Lepel Griffin, supported Mr. Batten's arguments, while Mr. Samuel Smith, M.P., and Mr. J. G. Alexander spoke from the point of view of the Society for the Suppression of the Opium Trade. As there was not time to finish the discussion, those who had sent up their names were invited to write out their remarks for publication in the Society's *Journal*. The desire of the Society to give a fair hearing to both sides in the controversy seems to have afforded much satisfaction. On April 7th, Dr. J. Augustus Voelcker, in an excellent paper on "The Agricultural Needs of India," summed up the results of his recent official visit to the East. Sir John Strachey presided, and practical speeches were delivered by General J. Michael, the pioneer of forestry in India, Sir Charles Bernard (Secretary of the Revenue Department, India-office), Lord Reay, and several other gentlemen of eminence, who explained what is being done in the Western Presidency to introduce improved agricultural methods. On April 2nd, Sir William Wedderburn, Bart., in a paper on "The Reorganisation of Credit in India," pleaded for the establishment of land banks. The final meeting was held on May 19, when a most valuable paper, by Mr. J. A. Baines, on "The Administration of the Imperial Census of 1891 in India," was read, and amongst the speakers was Sir W. C. Plowden, K.C.S.I., M.P., Mr. Baines's predecessor in the office of Chief Census Commissioner for India.

III.—Foreign and Colonial Section.

At the opening meeting of the Session, Mr. Ernest Satow, C.M.G., read portions of a journal which he kept while on an official tour through the Laos States of Upper Siam, and gave an interesting account of the people, trade, and geographical features of that little known region. Mr. Satow having kindly left his journal with the Society, it is intended to publish a further extract therefrom in the autumn.

On February 16th, Mr. Lewis Atkinson, the manager of the forthcoming Exhibition at Kimberley, South Africa, read a paper descriptive of the objects for which that Exhibition is being promoted, and the inducements held out to British manufacturers to be represented. The paper was supplemented by an interesting collection of photographic views.

The paper read at the meeting held on the 15th March had as its subject, "Peru: its commerce and resources." The author, Mr. F. A. Pezet, Consul-General for Peru in this country, described with much completeness the natural wealth of Peru and the growing importance of its manufactures. He urged the need of capital in promoting sound native industries, and the suitability of certain portions of the country for immigration.

On April 5th, the Rev. John McLean delivered an interesting address upon the "Red and White Races of Manitoba and the

North-West." He testified to the success which had attended the policy of the Government of the Dominion in its dealings with the Indians.

At the meeting on April 26th, Sir Edward Braddon, K.C.M.G., read a paper on "Australasia: its progress and resources." He gave a most striking account of the struggles and privations of the early settlers, and sketched the development of all the Australasian Colonies. In the discussion which followed, the financial policy of these colonies was justified by the Agents-General present.

The concluding paper of the Session was entitled "The Extension of Colonial Trade," and was an appeal by its author, Colonel Howard Vincent, C.B., M.P., for a preferential tariff in favour of colonial and Indian goods.

IV.—Applied Art Section.

Mr. William Morris opened the Session of this Section on January 26, with a paper on "The Woodcuts of Gothic Books," in which he pointed out the distinctive characteristics of the various classes of illustrated books produced during the 15th and early years of the 16th centuries. Mr. Morris showed a fine series of lantern slides of the woodcuts of the different schools, and drew especial attention to the fact that, in these old illustrated books, the illustrations did not bear a mere accidental connection with the other ornament and the type, but that the whole book formed one harmonious work of art. He further urged that this same principle should guide the production of the illustrated books of to-day.

At the meeting of February 23, Mr. J. William Tonks read a paper on "The Artistic Treatment of Jewel and Address Caskets," in which he traced the history of these artistic objects from the earliest times, showing the great variety of forms in which they were produced. He also described some of the most important specimens of modern caskets. The paper was illustrated by some fine examples of old caskets, selected from the South Kensington Museum, which were kindly lent by the Science and Art Department.

At the third meeting, on March 29, Mr. E. Roscoe Mullins drew attention to "The Decorative Uses of Sculpture," and showed in his paper how sculpture was at its best when treated in connection with architecture, and how unsatisfactory in treatment and position the isolated statue really is. Mr. Mullins advocated the filling-up of the niches of our public buildings, such as St. Paul's Cathedral, with statues of great men. The paper was illustrated by lantern slides of fine examples of decorative sculpture, from Assyrian to modern times.

Mr. C. Purdon Clarke read a paper on "English Brocades and Figured Silks," on April 12, in which it was shown that English silk manufactures were slowly emerging from a long period of depression, and that fine ornamental silks could now be produced in England at a lower price than would be charged either in France or Germany. Mr. Purdon Clarke collected, for exhibition at the meeting, a magnificent series of silks manufactured in England, which were exquisite in colour, elegant in design, and superb in texture.

It was announced that Mr. George T. Robinson would read a paper on "Decorative Plaster Work," on May 17, in continuation of his valuable paper last Session on "Modelled Stucco Work," but, unfortunately, he was prevented by illness from carrying out his intention, and Mr. William Simpson kindly undertook to take his place with a paper on "Mud, a Material in Persian and Eastern Architecture." Mr. Simpson showed in this paper, from his own large experience, how extensively mud has been used as an architectural material, and how much light the investigation of the various examples throws upon the history of architecture.

The last meeting, on May 31, was devoted to a paper on "Lustre Ware," by Mr. William De Morgan, in which he traced the history and explained the technique of this beautiful art product. In illustration of the subject of his paper, Mr. De Morgan exhibited a small collection of specimens of modern lustre ware, which were remarkable for the vigour of their decoration and the beauty of their colour.

V.—Cantor Lectures.

The first of the series of Cantor Lectures for the present Session was by Mr. A. P. Laurie, the subject being, "The Pigments and Vehicles of the Old Masters." The lectures contained the results of Mr. Laurie's own investigations, and may be commended to the notice of artists, as also the lectures and papers on the same subject by Mr. Laurie himself, Mr. Holman Hunt, and Professor J. M. Thomson. Professor George Forbes, in his lectures in 1888, elaborated the principles on which, so far as is at present known, electrical distribution may be based. In the course which he delivered after Christ-

mas, he showed how electrical science had been developed since the date of his previous course. He was followed by Professor William Robinson, who gave an account of the increasing uses of petroleum engines, and pointed out the advantages belonging to this type of motor. The next series was by Mr. Bennett H. Brough, on "Mine Surveying," an important subject which has not hitherto been treated in any series of Cantor Lectures. The concluding course of lectures for the session was by Dr. Percy Frankland, on "Recent Bacteriological and Chemical Research in connection with the Fermentation Industries." Professor Frankland gave a very lucid exposition of the recent advances which had been made on the study of micro-organisms, and the industrial applications of that study.

VI.—Juvenile Lectures.

The usual short course of lectures, adapted for a juvenile audience, were given during the Christmas holidays, the lecturer being Prof. J. M. Thomson, and the subject, "The Three States of Matter: solid, liquid, and gaseous." The lectures, which were well received and gave great satisfaction to the audience, were illustrated by a brilliant series of experiments, arranged by Prof. Thomson and his assistant, Mr. Jackson.

VII.—Howard Lectures.

It was announced, in the last report of the Council, that Professor Unwin had undertaken to deliver a course of lectures on "The Development and Transmission of Power from Central Stations." Unfortunately, after all the arrangements had been made, Professor Unwin was prevented by illness from carrying them out. He has, however, promised to give the course during the next Session.

VIII.—Albert Medal.

The Albert Medal for the present year has been awarded by the Council, with the approval and sanction of the President, H.R.H. the Prince of Wales, to Thomas Alva Edison, "in recognition of the merits of his numerous and valuable inventions, especially his improvements in telegraphy, in telephony, and in electric lighting, and for his discovery of a means of reproducing vocal sounds by the phonograph."

IX.—Medals for Papers.

The Council have awarded the Society's Silver Medal to the following readers of Papers during the Session 1891-2:—

At the Ordinary Meetings:—

To Prof. Silvanus P. Thompson, F.R.S., for his paper on "Measurement of Lenses."

To G. H. Robertson, F.C.S., for his paper on "Secondary Batteries."

To Captain F. E. Younghusband, for his paper on "The Pamirs."

To Prof. Vivian B. Lewes, for his paper on "Spontaneous Ingnition of Coal, and its Prevention."

To Robert S. McCormick, for his paper on "The Trade Relations of Great Britain and the United States."

To Captain W. de W. Abney, C.B., F.R.S., for his paper on "Colour Blindness."

To F. E. Ives, for his paper on "Composite Heliochromy."

In the Foreign and Colonial Section:—

To F. A. Pezet, for his paper on "Peru: its Commerce and Resources."

To Sir Edward Braddon, K.C.M.G., for his paper on "Australia: its Progress and Resources."

In the Indian Section:—

To G. H. M. Batten, for his paper on "The Opium Question."

To Dr. J. Augustus Voelcker, for his paper on "The Agricultural Needs of India."

To Jervoise Athelstane Baines, for his paper on "The Administration of the Imperial Census of 1891 in India."

In the Applied Art Section:—

To William Morris, M.A., for his paper on "The Woodcuts of Gothic Books."

To C. Purdon Clarke, C.I.E., for his paper on "English Brocades and Figured Silks."

To William De Morgan, for his paper on "Lustre Ware."

Mr. Dredge, being a member of Council, and, therefore, under the usual practice of the Council in such cases, not eligible for the award of a medal, thanks were voted to him for his paper on "The Columbian Exposition at Chicago, 1893."

X.—Mulready Prizes.

As announced in last year's report, the Council are offering, under the Mulready Trust, two Gold Medals, or two prizes of £20 each, for competition among the students of Schools of Art in the United Kingdom in 1892 and 1893, one in each year, for drawings from the nude. The Science and Art Department have consented to assist the Society by allowing the adjudication to be made by their Examiners.

XI.—Stock Prize.

The Council have also offered under the John Stock Trust a Gold Medal, or a prize of

£20, to the student of a School of Art who shall send in at the competition of 1892 the best original design for architectural decoration, by means of wall-painting, stucco, carving, mosaic, or any other method. As in the case of the Mulready Prize, the adjudication will be made by the examiners of the Science and Art Department.

XII.—Owen Jones Prizes.

The prizes have been awarded annually, since 1879, on the results of the annual competition of the Science and Art Department, to students of the Schools of Art who produce the best designs for household furniture, &c., on the principles laid down by Owen Jones. As usual, six prizes were offered last year, each prize consisting of a bound copy of Owen Jones's "Principles of Design" and a Bronze Medal. A list of the successful candidates has appeared in the *Journal*.* An equal number of prizes has been offered for the present year (1892), and the result of the competition will be published in the *Journal* as soon as it is received from the Science and Art Department.

XIII.—Fothergill Prize.

In answer to the offer made, as stated in the last report of the Council, under the terms of the Fothergill Trust, of a Society of Arts Gold Medal or £20, for "the best Invention, having for its object the Prevention or Extinction of Fires in Theatres or other places of amusement," eighteen competitors submitted designs, models, essays, samples, or suggestions. The Committee appointed to consider the award reported that, after a careful examination of the various proposals, they could not find any one which was, in their opinion, of sufficient merit, and coming sufficiently within the terms of the offer, to justify them in recommending it for the distinction of a Society of Arts Medal.

The Council regret that the offer should not have produced more satisfactory results, but they agree with the Committee, that no good purpose would be served by making an award to any invention which was not of decided novelty, importance, and value, and the competition was not successful in bringing out any such invention. The Council have, however, decided to publish in the *Journal* an essay sent in by Mr. E. A. Woodrow, which, although useful, did not, in their opinion, come within the terms of the offer.

* See *Journal* for September 18, 1891, p. 823.

XIV.—Benjamin Shaw Prize.

It was announced in the last report of the Council that they had asked the Committee of the International Congress of Hygiene to assist them in awarding the prizes founded by Mr. Benjamin Shaw for Industrial Hygiene. Unfortunately, but little response was made to the offer, and of the few competitors who entered none were recommended by the Committee of the Congress as suitable for the award.

XV.—Prizes for Drawing.

For the past three years the Council have offered twelve Bronze Medals for drawings sent in by students to the annual exhibition held by the Drawing Society, which, during its four years of existence, has greatly stimulated the teaching of drawing in the upper schools. The annual exhibition of 1892 showed how many different kinds of drawing are useful in developing the society's plan of making drawing a means of general education. The exhibition consisted of 529 drawings by about 500 boys and girls selected from nearly 15,000 in 78 public schools, high schools, and grammar schools. In addition to carrying out the work of the exhibition, the society holds annual examinations for schools, and awards certificates to competent teachers. The Council feel assured that useful work is done by this society in encouraging the study of drawing in middle-grade schools, and have, therefore, acceded to the application of the Drawing Society to renew the offer for next year.

XVI.—Memorial Tablets.

No tablet has been erected since the last year's report, but one is now in hand, and will shortly be placed on Bertram-house, Hampstead, where Sir Rowland Hill, the founder of the penny post, resided, from 1849 until his death, on 27th August, 1879. The house is now in the possession of the Metropolitan Asylum Board, who have given permission for the erection of the tablet.

XVII.—Examinations.

The number which entered for the Society's Examinations shows a gratifying increase, 2,928 having been examined, which is the largest number of candidates who have ever presented themselves to the Society of Arts Examinations since their institution in 1856, being an increase of 261 upon last year, when the numbers were 2,667. The numbers of papers

worked was also nearly equal to the largest number produced under the original system of examinations when the subjects had a far wider range than at present. In 1869, 2,160 candidates were examined; at that time the Examinations were free, and there was a choice of 36 subjects. The number of papers worked in that year was 3,193; this year, with only 17 subjects, 3,143 papers were sent in.

The standard may also be taken to be improving, for the number of First-class certificates which will be issued is 379. Last year there were 295, when 2,460 candidates were examined; 939 Second-class certificates, and 1,180 Third-class will be issued this year. The actual number of failures (645) is less than last year, when the failures to pass amounted to 651.

The largest number of candidates was as usual attracted by Book-keeping, for which 1,375 entered. The next largest was in the subject of Shorthand, 616. In English there were 156, French 155, Arithmetic 123, German 122, Spanish 90, Italian 9, Portuguese 5, and 98 for Typewriting.

Neither Russian, Danish, Chinese, nor Japanese attracted any candidates.

Domestic Economy, for which the number in recent years has not been very large, shows a considerable increase, 123 candidates having been examined. Last year there were only 43. In Theory of Music there has been considerable increase this year, 239 candidates having entered as against 131 last year. In previous years this subject has shown a decline.

The offer of medals, and of the prizes for which the Society is indebted to the liberality of various of the City Companies, has certainly been, during the past two or three years, of considerable value in raising the standard of the Examinations, and it is probable that the increased proportion of First-class certificates may, to a very large extent, be attributed to these offers. The Council hope that the Companies—viz., the Goldsmiths, Mercers, Skinners, Salters, and Clothworkers—who have assisted in the past, will continue their liberal aid in the future.

It should be added that the Special Examination for School Board teachers, to which reference was made in the last Report, was duly held, as announced, in September. For this examination 423 candidates were examined, and there were awarded 12 First-class, 117 Second-class, and 196 Third-class certificates. These numbers should be added to the totals of the regular examinations, which were held in March last. A total number is thus reached of 3,351 persons examined by the Society during the Session just completed.

XVIII.—Practical Examinations in Music.

The number of candidates examined this year is 245, showing a decrease on that for 1891, when 276 were examined. The increase last year was no doubt due to the offer of medals, which induced many candidates of former years to present themselves again with the view of obtaining a medal. This year eight candidates obtained full marks, and will, in consequence, receive Bronze Medals. As several candidates took more than one subject, there were 262 examinations, resulting in the award of 102 First-class and 132 Second-class Certificates, only 28 being failures. Two candidates entered for the Honours Certificates, but neither was successful.

XIX.—Standard of Colour.

The Committee which, as stated in the last report of the Council, was appointed last Session to consider the practicability of formulating a standard of colour for practical purposes, has held several meetings. They have decided on a list of names for standard colours, and have selected tints which they consider represented by those names. Captain Abney has very kindly undertaken to examine all these colours and to prepare, by means of his colour-patch system, a formula for each of them, by means of which a patch of light accurately representing the standard colour can be produced at any time and place. The Committee hope that, when their work is complete, the list of standard colours thus produced may be of practical value for many industrial applications.

XX.—Chicago Exhibition, 1893.

Among the most important departments of the Society of Arts' work during the past year has, as the members are well aware, been in connection with the great International Exhibition which is to be held at Chicago next year.

In March, 1891, Mr. Robert Lincoln, the American Minister to Great Britain, made on behalf of his Government a formal application to Lord Salisbury, asking that this country should take part in the proposed Exhibition, and received the reply that a Royal Commission should be appointed for the purpose.

No immediate action was taken, but as the result of some informal negotiations, the

Under Secretary of State for Foreign Affairs, in June of last year, applied to the Attorney-General, the Chairman of the Council of the Society, to know whether the Society would undertake the duties connected with the organisation of the British section of the Chicago Exhibition if a grant of £25,000 were appropriated by the Treasury for the purpose.

The proposal was, in the first instance, submitted to H.R.H., the President of the Society, and was approved by him. The Council then went very carefully into the question, and came to the conclusion that if the exhibitors were willing, as in the case of the Paris Exhibition of 1889, to bear a share of the expenditure, the grant proposed might be made to suffice. They accordingly requested their Chairman to submit a memorandum stating the conditions on which they would be willing, on behalf of the Society, to undertake the proposed duties.

On the 9th July, Sir James Fergusson, as Under Secretary of State for Foreign Affairs, addressed a letter to the Attorney-General stating that the Lords of the Treasury would accept the offer of the Society to undertake the organisation of the British section in Chicago in 1893, and that they had requested tho Home Office to take the necessary steps for constituting the Council of the Society for the time being, a Royal Commission for this purpose.

This Commission was actually issued on the 26th August, but in the meantime the Council of the Society had anticipated their appointment by communicating with the India Office and the Colonial Office, and requested that steps might might be taken to inform the British colonies and the Indian Government of the action which Her Majesty's Government proposed to take with regard to the Chicago Exhibition.

They had also the pleasure of receiving the Special Commission sent over by the Board of Managers of the Exhibition with the view of securing the co-operation of the various European Governments. This Commission, which consisted of the Hon. Benjamin Butterworth, Judge Lindsay, Mr. Ferdinand Peck, Major Handy and Mr. W. H. Bullock, arrived in England in July, 1891. Their visit was of great value in providing information as to the general scope and character of the Exhibition, and of the organisation which was provided for carrying it out. In the report which they made on their return, they expressed in warm terms their appreciation of their reception here, and their belief that it largely contributed to the ultimate success of their mission.

The first meeting of the Royal Commission was held on the 3rd September, when instructions were given to Sir Henry Trueman Wood, who had been appointed Secretary to the Commission, to proceed to Chicago for the purpose of making all the necessary preliminary arrangements. Mr. Dredge, one of the members of the Commission, kindly volunteered to accompany Sir Henry Wood, and these two gentlemen were authorised to visit Chicago on behalf of the Commission. On their return they made a joint report, which was submitted to the Commission on the 21st October, and appeared in the *Journal* of the Society on the 23rd October. The Royal Commission are also much indebted to Mr. Dredge for the admirable paper which he read before the Society on the 9th December,* giving a very full description of the Exhibition buildings, and of the preparations which had been made for the Exhibition.

As soon as the necessary information had been obtained, a circular was issued to those firms who had taken part in recent International Exhibitions, and to a large number of firms who might be likely to exhibit at Chicago, inviting them to take part in the Exhibition. Advertisements were also inserted in the principal English, Scotch, and Irish newspapers. The limited amount of the grant made by the Government rendered it necessary that the amount should be supplemented by charges for the space occupied by exhibitors, and, indeed, the grant was made on that understanding. A sliding scale was arranged, under which the highest charge was 5s. per square foot of superficial area, the lowest 2s. 6d. per square foot; the amount varying according to the size of the space proposed to be occupied by the exhibitor.

The date by which all applications were to be received was fixed for the 29th February, 1892. In answer to the circular, a large number of applications were received, though it was found that the high Customs' duties now levied in the United States deterred manufacturers in many important departments of industry from taking part in the Exhibition. Some, but not many, objections were also taken to the charge for space.

When the vote on account came before the

* The paper appeared in the Society's *Journal* on the 11th December.

House of Commons in Committee of Supply, great exception was taken to the smallness of the amount granted, and there was a strong expression of opinion from all sides of the House that the amount should be largely increased. The Commission fe .themselves justified by this expression of feeling in urging upon the Chancellor of the Exchequer the desirability of placing a larger sum at their disposal, especially in view of the fact that the contributions of all the other great countries which proposed to take part in the Exhibition were on a much more liberal scale. As a result of this application, which was strenuously supported by the Chairman of the Commission, Sir Richard Webster, the Chancellor of the Exchequer, on the 14th April, 1892, intimated that Her Majesty's Government were willing to increase the grant to the Royal Commission from £25,000 to £60,000, on the understanding that space should be provided free to British exhibitors.

The natural result of this liberality on the part of the Government has been a considerable increase in the number of applications, and although these received since April last include a considerable proportion of a less important class than received under the earlier arrangement, there are yet a number of very important firms who have decided to exhibit now that space is free, but who would not have done so had payment for space occupied been added to the very heavy charges which are of necessity incurred by exhibitors at a foreign Exhibition.

The Council have much pleasure in informing the members that they have no fear as to the adequate representation of the industries of Great Britain and Ireland as a whole, although there are, of course, important branches of industry which are so affected by the present high Customs tariffs of the States, that they will not be sufficiently represented at Chicago.

The buildings in which the exhibits will be placed will be provided in a completely finished condition by the American Executive, but the Royal Commission have thought it desirable that they should contribute one building to the Exhibition, and they have decided therefore to erect, on an admirable site on the shore of Lake Michigan, which was placed at their disposal by the Directors of the Exhibition, a building which might serve for offices and headquarters of the section. Colonel Edis, who has kindly accepted the office of hon. architect to the Commission, has furnished them with a design.

The building will be generally characteristic of the best type of English half timber houses of the 16th century, of which there are so many good examples still extant. It is proposed to use terra-cotta somewhat largely in the lower storey, with red brick facing and mullioned windows, so that the building may be a typical example of an old English house. The upper portion will be of half timber construction, with overhanging and projecting gables. As the building will be seen from all points, each façade has had to be treated architecturally. The plan forms three sides of a quadrangle with the open side next the lake, enclosed by a raised terrace with balustrade. The centre on the front or inland side will be recessed, with steps leading from both sides up the covered portico, which will open into a large central hall; off this will be, on one side, large library and reception rooms, and on the other, the secretary's office and the other rooms required for the work of the Commission. On the first floor will be a large suite of rooms and offices. It is intended to fit up all the principal rooms with wall panelling and elaborate ceilings, after the manner of some of the best English country houses. The whole of the internal fittings and furniture will be executed from Colonel Edis's designs by Messrs. Johnstone, Norman and Co., of New Bond-street. The foundations of the building have already been commenced, and the superstructure will be pushed forward with all speed, so as to be finished complete for the opening in May next.

Besides the necessary offices, the house will contain some large rooms, suitable for meetings of juries, receptions, &c., and the Commission hope that the accommodation thus provided may be found useful, not only for their own purposes, but for those of the various Colonial Commissions.

To assist them in their work, the Royal Commission have invited a number of gentlemen to act on various committees. A list of these will be found in the hand-book of regulations, published under the authority of the Commission. The most important of these committees is the one for the Fine Art Section, presided over by Sir Frederick Leighton, and in their hands have been left all the arrangements for securing what the Commission hope will be a representative gallery of British Art.

In accordance with the special request of the Chicago Executive, the Commission have also

appointed a Ladies' Committee to look after British contributions to the collection of women's work which is to form a prominent feature of the Exhibition.

At the outset of their proceedings an invitation was addressed by the Commission to all the Chambers of Commerce in the United Kingdom, asking whether they would act as Local Committees for the Exhibition. From many of these a favourable response was received; a list of them will also be found in the handbook above referred to. The local committee for Dublin consists of representatives of the Corporation of Dublin, the Royal Dublin Society, and the Chamber of Commerce. It is hoped that the exertions of this committee, supplementing those which were made before its formation by the Commission themselves in Ireland, will ensure a good representation of the principal Irish industries, and of this it is satisfactory to say there is every prospect.

In reply to the request addressed to the colonies through the Colonial Office, information has been received that the following colonies intend to be represented at Chicago:—Canada, New South Wales, Victoria, Tasmania, Cape Colony, Ceylon, Mauritius, British Guiana, Jamaica, Trinidad, Bermuda. Many of these have made large contributions, and have applied for a considerable amount of space.

The Commission regret that it still appears uncertain what part will be taken in the Exhibition by India. The India Office, after consultation with the Indian Government, declined to make any special grant, and in the absence of official encouragement, it appears improbable that any large or important contribution may be expected from India. A number of Indian manufacturers have, however, individually applied for space to exhibit their goods, and applications have also been received from several importers of Indian tea in this country, and from some Indian tea-growers on the spot.

As it is probable that a number of members of the Society of Arts may desire to visit Chicago during the time of the Exhibition, the Council have in view the making of special arrangements for their accommodation. They have already been informed that special facilities will be afforded to members of the Society of Arts visiting the Exhibition, and they hope later on to be able to announce that arrangements may be made for facilitating their journey to that city.

In addition to the contributions made by the exhibitors, the Commission have been promised various important exhibits, including a collection of educational apparatus from the London School Board; a collection illustrating the work of the Science and Art Department; a series of illustrations of the work produced by the Ordnance Survey; a similar series of the work of the Geological Survey; a collection of photographs showing the best work produced by English photographers, a collection of British minerals, a collection of metallurgical products, specially prepared for the section; a map illustrating the discoveries of Englishmen in North America, which is being kindly prepared by the Royal Geographical Society.

The Commission have issued, for the benefit of exhibitors and others, a "Handbook of Regulations and General Information." The handbook contains lists of the Commission, of the various Committees, and of the Colonial Commissioners, Synopsis of the Classification, General Regulations, Regulations of the British Section, Traffic Arrangements and Customs Regulations, description of the various Departments, Abstract of the McKinley Tariff Rates, Description of Chicago and the Exhibition, and account of the routes to the city. The information, which is presented in a concise form, will be valuable to all who contemplate a visit to Chicago. Copies of the handbook can be obtained on application to the Secretary.

XXI.—H.R.H. The Duke of Clarence and Avondale, K.G.

The late Duke of Clarence was elected a Vice-President of the Society of Arts in 1885, on the nomination of H.R.H. the Prince of Wales, President of the Society. The Council, feeling that a special loss had been suffered by the Society in consequence of his sudden death, felt it their duty to express to the President of the Society their sense of this feeling, and accordingly a memorial was addressed to His Royal Highness on the 18th January by the Council.*

XXII.—New Council.

The following are the Vice-Presidents who retire from the Council at the end of the Session:—The Attorney-General, M.P., Sir Francis Dillon Bell, C.B., K.C.M.G., Sir Philip Cunliffe-Owen, K.C.B., K.C.M.G., C.I.E., James Staats Forbes, Thomas Hawksley, F.R.S. To fill their places the Council

* See *Journal*, Jan. 22, 1892.

propose the following :—Sir Frederick Leighton, Bart., President of the Royal Academy, who has served before as a Vice-President of the Society, and who has for some time back taken an active part in the work of the Chicago Exhibition, in his capacity as President of the Fine Art Committee; Sir Villiers Lister, K.C.M.G, who retired by seniority a year ago, having served for a considerable period on the Council; Sir Albert Kaye Rollit, M.P., LL.D., Chairman of the London Chamber of Commerce; Mr. Michael Carteighe, President of the Pharmaceutical Society, Mr. C. M. Kennedy, C.B., and Mr. J. Biddulph Martin, who have occupied seats on the Council for some years past. Sir James Douglass and Mr. George Matthey retire from the Council by seniority.

To fill the five vacancies among the ordinary members of the Council, the following names are proposed:—Sir Edward Braddon, K.C.M.G., the Agent-General for Tasmania; Mr. Alfred Carpmael, who after serving since 1882, on the Council, retired by seniority last year; Sir George Hayter Chubb, whose experiences in exhibition work the Council think cannot fail to be of service to them; Mr. Walter Harris, who was sheriff of London in 1890; and Professor Le Neve Foster, the son of Mr. P. Le Neve Foster, for many years the well-known and much respected Secretary of the Society.

It will be noticed that amongst the names of the retiring members are those of The Attorney-General and Sir Philip Cunliffe-Owen. The Council felt it would be a serious loss to the Royal Commission for the Chicago Exhibition if they were deprived of the services of the Chairman, who had devoted so much of his time to the work since the Commission was appointed, and they were of course also anxious that they should not lose the benefit of Sir Philip Cunliffe-Owen's great experience in connection with Exhibitions, they therefore proposed to the general body of members at the special meeting summoned for the purpose on May 18, that a modification should be made in the bye-laws which would authorise them to add during the next two years six names to Council, either in the capacity of vice-presidents or ordinary members of the Council. The resolution proposed for the purpose was unanimously adopted, and the Council are therefore authorised to make the suggested additions to their number after the Annual Election is completed. They propose to add the names of the Attorney-General and Sir Philip Cunliffe-Owen, and also of some other gentlemen whose adhesion they think would strengthen the Council in its capacity as a Royal Commission for the Chicago Exhibition.

XXIII.—List of Members.

The total number of life members, subscribing members, and institutions in union which subscribe to the Society from their own funds is 3,310. During the year 1891-92, 324 members have been removed from the list by death or resignation. During the same period 282 have been elected.

XXIV.—Conversazione.

The Council have, by the permission of the Lords of the Committee of Council on Education, again arranged for the holding of the Conversazione at the South Kensington Museum. The meeting will take place this evening, and the arrangements to be made for the entertainment of the company have already been announced in the *Journal.*

XXV.—Obituary.

The Society has to deplore the loss by death during the past year of several eminent and active members. Two recipients of the Albert Medal — Sir George Airy, for many years Astronomer Royal, and Dr. A. W. Hofmann, the distinguished chemist—have also passed away during the year just ended. Dr. Alfred Carpenter and Dr. Tidy both read important papers on sanitary subjects before the Society, and the latter received in 1889 the Swiney Prize for his work on Legal Medicine. The Earl of Lichfield held the office of vice-president in 1871, and Sir James Brunlees was a member of Council in 1876. Mr. Mark Henry Blanchard, who was one of the earliest revivers of the use of terra-cotta, had been, at the time of his death, a member of the Society for nearly thirty years. Sir Francis Knowles, Bart., F.R.S., who died in March last at the great age of ninety, read a paper before the Society in 1873, on a "Method of Refining or Converting Cast Iron or Steel." Mr. Willoughby Smith, the eminent electrician, was a member for over twenty years, and Mr. Leonard Wyon, a member since 1852, had for many years struck all the Society's medals. The sudden death of Mr. P. W. Willans in the midst of his valuable labours, and at the early age of forty, gives cause for special regret. The Society has also lost the valuable services of Mr. William

Alexander Barrett, who had acted as the Examiner in Music since 1879.

Obituary notices of the above, and of some other members who died during the last twelve months, have appeared in the pages of the *Journal.*

XXVI.—FINANCE.

The Treasurers' annual statement of receipts and expenditure, which appeared in last week's *Journal*, in accordance with the Society's Bye-laws, shows a satisfactory state of the Finances. The amount received from members shows a slight increase, due to the Life Composition Fees, the amount from that source being £714, the largest sum received since 1862, when the Society had a great influx of members in consequence of its connection with the International Exhibition of that year. It will be seen that, although there is an increase in the number of candidates, the expense of the working of the Society's Examinations during the year has been covered by the fees received. A sum of £89 10s. has been received from a bequest by the late John P. Stocker, Esq. The Treasurers have been enabled to invest the sum of £1,378 in the purchase of Consols, retaining as large a balance as that with which they commenced last year. The excess of assets over liabilities is estimated at £17,771.

The CHAIRMAN moved the adoption of the report, and said that he felt sure the meeting would consider it thoroughly satisfactory as a record of the important work done by the Society, and of the valuable papers which had been read at the meetings during the past year. In allusion to the absence of the Secretary, he said he was sure that Sir Henry Wood was doing good work at Chicago, and that, in fact, they had evidence of this, as a cablegram had just been received from him to say that the question of pricing of goods by British exhibitors, which had given cause for anxiety, had been settled in every way satisfactorily.

The DUKE OF ABERCORN, Vice-President, seconded the motion for the adoption of the report.

Mr. WYATT PAPWORTH called attention to the terms of the offer of the Mulready and Stock prizes, and said that he did not think that the offer should be confined to students in the Schools of Art of the United Kingdom. He further thought that the Stock prize might with advantage be devoted to the encouragement of architectural design, and not merely to architectural decoration.

The CHAIRMAN said that the terms of the Mulready trust were that the offer should be confined to students in the schools of art, but that this was not the case with respect to the Stock prize; and he was sure that Council would give due consideration to Mr. Papworth's suggestion.

Mr. HYDE CLARKE said that he thought it very satisfactory that there had been so large a number of entries for the Spanish examinations. These were of special value, and it was found that a knowledge of the Spanish language was a most important acquirement among commercial men at the present time. With respect to Chinese, he thought perhaps an attempt to further a colloquial knowledge of that language would meet with success, as a knowledge of the language spoken at the commercial centres would be very valuable to members of mercantile firms. He supported Mr. Papworth's suggestion in respect to the Stock prize.

The ballot having remained open for one hour, and the Scrutineers having reported, the CHAIRMAN declared that the following had been elected to fill the several offices. The names in *italics* are those of members who have not, during the past year, filled the office to which they have been elected.

PRESIDENT.

H.R.H. the Prince of Wales, K.G.

VICE-PRESIDENTS.

H.R.H. the Duke of Edinburgh, K.G.
Sir Frederick Abel, K.C.B., D.C.L., D.Sc., F.R.S.
Duke of Abercorn, C.B.
William Anderson, M.Inst.C.E., D.C.L., F.R.S.
Sir George Birdwood, K.C.I.E., C.S.I., M.D., LL.D.
Sir Edward Birkbeck, Bart., M.P.
Sir Frederick Bramwell, Bart., D.C.L., F.R.S.
Major-General Sir Owen Tudor Burne, K.C.S.I., C.I.E.
Michael Carteighe.
Lord Alfred S. Churchill.
Prof. James Dewar, M.A., LL.D., F.R.S.
Major-General J. F. D. Donnelly, C.B.
Sir Henry Doulton.
Sir Douglas Galton, K.C.B., D.C.L., F.R.S.
C. Malcolm Kennedy, C.B.
Sir Frederick Leighton, Bart., P.R.A.
Sir Villiers Lister, K.C.M.G.
J. Biddulph Martin.
General the Right Hon. Sir Henry F. Ponsonby, G.C.B.
Wyndham S. Portal.
Sir Robert Rawlinson, K.C.B.
Sir Albert Kaye Rollit, LL.D., M.P.

ORDINARY MEMBERS OF COUNCIL.

Sir Edward Braddon, K.C.M.G.	John Fletcher Moulton, Q.C., F.R.S.
Alfred Carpmael.	William Henry Preece, F.R.S.
Sir George Hayter Chubb.	Prof. William Chandler Roberts-Austen, C.B., F.R.S.
James Dredge.	Sir Saul Samuel, K.C.M.G., C.B.
Francis Elgar, LL.D.	
Prof. Clement Le Neve Foster, D.Sc., F.R.S.	
Walter H. Harris.	
Alex. B. W. Kennedy, F.R.S.	

TREASURERS.

B. Francis Cobb.	Sir Owen Roberts, M.A., D.C.L., F.S.A.

SECRETARY.

Sir Henry Trueman Wood, M.A.

The CHAIRMAN proposed a vote of thanks to the scrutineers, which was seconded by the DUKE OF ABERCORN, and carried.

The DUKE OF ABERCORN proposed a vote of thanks to the Chairman (Sir Frederick Bramwell), which was seconded by Mr. C. M. KENNEDY, and carried.

Sir FREDERICK BRAMWELL responded, and the meeting was then adjourned.

Miscellaneous.

ROYAL SOCIETY OF NEW SOUTH WALES.

Information has been received that the Royal Society of New South Wales offers its Medal and £25 for the best communication (provided it be of sufficient merit) containing the results of original research or observation upon each of the following subjects:—

Series XI. (to be sent in not later than 1st May, 1892).—No. 37. "On the Iron Ore Deposits of New South Wales." No. 38. "On the Effect which Settlement in Australia has produced upon Indigenous Vegetation; especially the depasturing of sheep and cattle. No. 39. "On the Coals and Coal Measures of Australasia."

Series XII. (to be sent in not later than 1st May, 1893).—No. 40. "Upon the Weapons, Utensils, and Manufactures of the Aborigines of Australia and Tasmania." No. 41. "On the Effect of the Australian Climate upon the Physical Development of the Australian-born Population." No. 42. "On the Injuries occasioned by Insect Pests upon Introduced Trees."

Series XIII. (to be sent in not later than 1st May, 1894).—No. 43. "On the Timbers of New South Wales, with special reference to their fitness for use in construction, manufactures, and other similar purposes." No. 44. "On the Raised Sea-beaches and Kitchen Middens on the Coast of New South Wales." No. 45. "On the Aboriginal Rock Carvings and Paintings of New South Wales."

The competition is in no way confined to members of the Society, nor to residents in Australia, but is open to all without any restriction whatever, excepting that a prize will not be awarded to a member of the Council for the time being; neither will an award be made for a mere compilation, however meritorious in its way. The communication, to be successful, must be either wholly or in part the result of original observation or research on the part of the contributor.

The Society is fully sensible that the money value of the prize will not repay an investigator for the expenditure of his time and labour, but it is hoped that the honour will be regarded as a sufficient inducement and reward.

The successful papers will be published in the Society's annual volume. Fifty reprint copies will be furnished to the author free of expense.

Competitors are requested to write upon foolscap paper—on one side only. A motto must be used instead of the writer's name, and each paper must be accompanied by a sealed envelope bearing the motto outside, and containing the writer's name and address inside.

All communications to be addressed to the Honorary Secretaries, the Society's House, 5, Elizabeth-street, Sydney.

Correspondence.

BRITISH SHIPBUILDERS AND THE CHICAGO EXHIBITION.

From a report made to me by Commander Hoff, who has been visiting the Clyde and other shipbuilding centres, I am afraid that the firms do not thoroughly understand the advantages that might accrue to them from exhibiting at Chicago. I should, therefore, be pleased if the following facts can be brought under their notice:—

The recent Act of the American Congress, permitting citizens of the United States steamship companies of the United States to purchase one steamship abroad for everyone they build at home, is of greater importance to the British shipbuilder than any public Act in any country for half a century. It means that one-half of the steamships required in the United States for its growing trade may be purchased abroad. By special Act of Congress, four ships of British build, which have hitherto sailed under the British flag have been transferred to that of the United States; the *China* and *Foxall*

besides the well known cases of the *City of Paris* and the *City of New York*. This is practically a sale of four British built ships to American lines, and but the forerunner of a large business if the British ship builder is alive to the opportunity now held out to him.

The increased demand for freight carriers of the highest class and speed is evidenced by the growth in the business of one line, that of the Brazilian Steamship Company, which plies between New York and Rio. I repeat here, for emphasis, what I have said before on several occasions, that whereas less than one year ago the company above referred to found that one or, at the outside, two steamers per month were quite sufficient for freight offered, that company now employs fifteen steamers per month, of which thirteen sail under the British flag. The number employed is limited rather by the difficulty of securing ships than by the trade, which has grown so rapidly of late. Should circumstances require an increase in this number, the disposition will be rather to purchase new ships with all the modern improvements — which mean small coal consumption and lower running expenses—than to take any old ships which are lying in the docks, not only on account of the falling off in British trade, but also on account of their not being up to modern requirements.

The ship-yards of the United States have orders ahead which will keep them busy for some years, which in itself will make it impossible to meet increasing demand from these yards, so that for every two new ships constructed one must be ordered from foreign ship-yards. I need only refer to the increase in the demand which the construction of the Nicaragua Canal will bring about. The Republican and Democratic Conventions, recently held at Minneapolis and Chicago respectively, endorsed the proposition for Government aid to this canal, which assures its construction in the near future.

If the growth of trade on the Pacific coast of South America is at all comparable with the eastern coast, prominently with Brazil, the demand for ships for this trade will open a market for the British shipbuilder that in his most sanguine moments he has not looked forward to. Our own shipyards will be kept busy providing steamers for our own coastwise and inland trade, so that it is safe to say that the British shipbuilder will have a chance of competing with German and French shipbuilders to construct one-half of the new ships which the United States will require.

The German Government is interesting itself in this subject, and the ship building interest of Germany, though in its infancy as compared to Great Britain, will be represented in every detail.

The British ship builder may feel that he has nothing to fear from either France or Germany. There may seem little ground for such fear at this time, as there was little ground some years ago that the iron and steel industries of Great Britain had anything to fear from European competition. It is worthy of note in this connection, that while the export of iron and steel manufactures from Great Britain fell off 21 per cent. for the year 1891 as compared with the year 1890, the exports of iron and steel manufactures from Germany increased 19 per cent.

The manufacturers in every industry can well learn a lesson from these figures, and should be aroused by them to at least investigate the cause for this transfer of trade from British to German workshops.

ROBERT S. MCCORMICK.

72, Victoria-street,
June 28th, 1892.

General Notes.

BLACK HOLE OF CALCUTTA.—An account of a visit made to the newly-discovered site of the Black Hole of Calcutta was given in the *Englishman* (Calcutta) of 24th March. A number of photographic copies of an old plan of old Fort William, made by Lieutenant Will, or Wells, in 1753, were distributed to many of those present. Mr. C. R. Wilson, in the first instance, led the party to the excavations in the post-office compound, showing the position of the south curtain wall, and also the position of a small wall jutting off from this curtain wall on its south side. This wall, it was explained, was a boundary of the warehouses built against the south curtain in the year 1747. It was pointed out that these walls agreed with the plan of 1753, and that the old arcade within the post-office compound was a portion of the south side of the old fort. The party were next shown an excavation at the east gate of the post-office, showing, first, the east curtain wall; secondly, the wall containing the rooms built against the east curtain, which stopped here; thirdly, the corner where the foundation walls of the columns of the verandah along the east side of the fort met the foundation wall of the third line of arches along the south side of the fort. On comparison, it was clearly shown that these walls agreed with the plan of 1753, that the foot of the stairs, to the south-east bastion, came where the pavement marking the reputed site of the Black Hole now was, and that the real site of the Black Hole was immediately to the north of this pavement. In reference to this, Mr. Wilson added that Sir Charles Elliott was going to remove the pavement which was supposed to mark the site of the Black Hole, and place it where he (Mr. Wilson) had shown it ought to be placed.

The Telegraphic Address of the Society of Arts, and of the Royal Commission for the Chicago Exhibition, is "Praxiteles, London."

Journal of the Society of Arts.

No. 2,068. Vol. XL.

FRIDAY, JULY 8, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Chicago Exhibition, 1893.

EXECUTIVE COMMITTEE.

A meeting of the Executive Committee was held on Wednesday, 6th inst. Present: Sir Frederick Abel, K.C.B., F.R.S., in the chair; Alfred Carpmael, Francis Cobb, Sir Philip Cunliffe-Owen, K.C.B., K.C.M.G., James Dredge, John Biddulph Martin, Sir Owen Roberts, M.A.

COLLECTION OF GUIDE BOOKS, &c.

The Royal Commission are forming a collection of Maps, Guide Books, Photographs, Railway and Steamship Guides, Programmes, &c., and other printed matter likely to supply useful information to exhibitors at, and visitors to the Chicago Exhibition.

The collection is placed in the library of the Society of Arts for consultation by persons interested. It will be open to members of the Society, exhibitors, or their agents, and persons introduced by either of the above.

A considerable number of books, &c., have been collected, but the Royal Commission will be glad to receive any works suitable for the above purpose for addition to the Collection.

HANDBOOK OF REGULATIONS.

A "Handbook of Regulations and General Information" connected with the Royal Commission has been printed, and can be had on application to the Secretary of the Royal Commission, Society of Arts, John-street, Adelphi. The Handbook contains lists of the Commission, of the various Committees, and of the Colonial Commissioners, Synopsis of the Classification, General Regulations, Regulations of the British Section, Traffic Arrangements and Customs Regulations, descriptions of the various Departments, Abstract of the McKinley Tariff Rates, description of Chicago and the Exhibition, and account of the routes to the city.

PREVENTION AND EXTINCTION OF FIRE IN THEATRES.*

By Ernest A. E. Woodrow, A.R.I.B.A.

When, in 1883, the Society of Arts offered the Society's Gold Medal for the Fothergill Prize, I submitted to the Council a paper upon "The Prevention and Extinction of Fires in Theatres," and although the Council did not consider that my paper came within the terms of the prize, they had it printed in the *Journal* of the Society in April, 1884. It is evident that the Council deem this subject one of the greatest importance, as they again offer the Gold Medal for the Prevention and Extinction of Fires in Theatres. Although the views I expressed eight years ago are still on record in the Society's *Journal*, I will venture, even at the risk of repetition, to lay before the Council what I consider are the leading points to be observed on this subject, which is undoubtedly one of the greatest moment to the community at large. For this reason I may crave indulgence, after the lapse of time, in again drawing the attention of the Society to the construction of a theatre in relation to the prevention and extinction of fire.

The result of the competition for the medal in 1883 showed that the Council had no invention submitted to them which they considered would either prevent or extinguish fire in theatres. I endeavoured, at that time, to show how prevention and extinction of fires in this class of building depended entirely upon good building, good planning, and good fire appliances, not upon inventions; the same remedies of prevention also apply to panic—the outcome of fire. These views have been endorsed again, and but lately, by the greatest authority upon the subject, Captain Sir Eyre M. Shaw. Writing in one of the Reviews he remarks: "If a theatre is built on sound principles, suitably

* This paper was submitted to the Society in competition for the Fothergill Prize. The Council were of opinion that the essay did not come within the terms of the offer of the prize, but they decided that it should be printed in the *Journal* [see *ante* p. 673, Report of Committee on Fothergill Prize, and p. 776, Report of Council]. A former paper by Mr. Woodrow, on the same subject, was printed in the *Journal* in 1884 [see vol. xxxii., p. 350].

provided with fire-extinguishing appliances, and well managed, a panic does not cause loss of life; and this is not the only 'law' that may be evolved out of the evidence which is now available."

One cannot separate the consideration of the prevention of fires from that of the prevention of panic, for were fire not attended with the awful results of panic, the importance of this subject would be but small, in fact, it would be reduced to the simple question of the protection of property and vested interest; and, under such circumstances, I should not feel justified in presenting this paper to the Council. It will be remembered that in the report of the committee appointed by this Society, in 1883, to consider the prevention of fires in theatres, reference was made to the fact that, in the case of the Vienna Ring Theatre fire, many corpses were found seated in their places, sudden death from asphyxia having prevented any effort to use the means of escape.

It is far from my wish to deprecate the advantages of appliances and inventions to minimise the risk of fire; but what I wish to assert is, that a badly built, badly planned theatre, even when fitted with all the latest and most approved appliances, would not be a "safe" theatre, nor one in which the prevention and extinction of fire could be depended upon with any degree of certainty. Now, in a house where every detail of construction and planning has been observed, the simplest means will extinguish fire, and its construction prevent the fire spreading from one portion of the building to another. It is a case of the thoughtful study of detail, observation of the causes of fires in the past (small as well as great), and making provisions against the probability of recurrence: "The laws that may be evolved out of the evidence," as Captain Sir Eyre M. Shaw so aptly puts it. If we build according to these "laws," fire and panic in theatres will be reduced to a minimum, and even where fire does occur, panic will be averted.

In passing, may I be permitted to draw attention to a newspaper report of recent date: the circumstance therein described is trivial in itself, but sufficient to use as an illustration to show that by the observation of details provisions can be made to minimise the chances of fire; I have really chosen this example on account of its seeming unimportance, and to show that it is only by experience the difficulties of theatre planning can be overcome.

The *Globe* of 5th of last October reported an alarm of fire in a theatre, and stated that the "fire occurred in a dust-hole;" now it is well known how inflammable the refuse from a theatre is, composed as it is of shavings, papers, dust, and such like dry rubbish. In the list of the probable causes of fire, given by me in my paper in the Society's *Journal* will be found mentioned, "Darkness and dirt and keeping rubbish shavings, &c., on the premises." The "law" or lesson to be evolved from this circumstance is that "dust holes" in theatres are a source of danger, and the abolition of them a preventative of fire, also that rubbish should not be collected in a theatre but be removed daily; again, that trade refuse is a cause of danger from fire to a theatre, and that therefore the carrying out of trades in the house is a practice that should not be permitted. Every disaster, small or great, teaches a fresh lesson. The summing up of all this is, that a theatre should be so planned that such evils would be quite impossible. I could quote other instances of causes of fire equally trivial in themselves, which, but for their early extinction, would be disastrous in their results, and from which other instructions could be gathered. The above is, however, sufficient for my present purpose to prove that safety in theatres depends upon starting on the sound basis of a good honest study of every detail of theatrical business, ascertaining what risks attend each department, and making provisions to overcome the danger.

I shall endeavour to touch upon some of the most important points to be observed in theatre building; having the object of the prevention and extinction of fire in view, I shall not enter minutely into the details that I did in 1883, and I do not propose to accompany this paper with diagrams, although those I presented to the Council in 1883 would apply equally well to illustrate these remarks. In bringing the subject again before the Council, I shall be compelled to traverse much of the same ground, for I do not feel that I shall be justified in allowing this opportunity to pass without protesting against the false security likely to arise through placing good inventions in a badly built and planned house. I hope, indeed, to be able to strengthen my case by the additional years of experience gained since last I addressed the Council. One word as to extinction of fire before entering into details. I have failed, during the past eight years, to see

any reason to alter my opinion that, to extinguish fire, there can be no more efficient means than — given an ample water supply, a good fire watch.

Choice of Site as a Prevention of Fire.

Many theatres may, in themselves, be reasonably safe from fire; they may indeed be provided with the most efficient means of extinguishing fire, and yet, from their very position, they may be in constant danger—in danger from the adjacent and surrounding neighbouring premises. Again referring to recent newspaper reports, it was but a short time since that one of the London theatres was placed in an alarming position, through a fire in a neighbouring house; panic was averted through the timely interference of good management, and the house was cleared without mishap.

In glancing over the regulations enforced in foreign countries with regard to the site upon which a theatre should be built, the rules, we find, are far more stringent upon the Continent than in our own country. In Austria, new theatres must be erected perfectly isolated, and not less than 49 feet distant from the boundary of the land on which they stand. This seems a severe measure, but it is to prevent the spread of fire from other premises, as well as to allow ample means of exit. Small theatres in Austria may have the back wall of the stage abutting on other houses, but the other sides must be free.

In St. Petersburg all theatres must have an open space upon every side. In Brussels every theatre must be separated from adjoining premises by an open space or thick brick wall; when the open space is less than 10 ft. 6 in. there must be no window overlooking it belonging to adjacent premises.

People who invest their money in theatrical undertakings in our country, assert that the imposition of such regulations as these would render theatrical enterprise in this land impossible, as the price of land in the locality where theatres pay would prohibit the erection of such places of entertainment on isolated sites. It is true that it has been proved by experience, that the circle within which to build paying theatres is but small, the land dear, and the opportunities of acquiring suitable sites few and far between; in fact, it is only when street improvements take place that opportunities arise to afford plots of land of such merit as the one occupied by the Royal English Opera-house.

Not only is an isolated site a desideratum for preventing fire, but it is also requisite for extinguishing fire, as a building surrounded by wide streets is easily accessible to the fire brigade engines and escapes. It is unnecessary here to add the arguments in favour of perfect isolation with regard to satisfactory exits and the prevention of panic; and it is also unnecessary to consider what, if any, curtailment of this requirement may be made with safety.

In countries, however, where State aid is not obtainable, such rigid rules as those framed in continental cities have been found to be impracticable. The most recent laws with regard to theatre sites are those of the London County Council and New York City, both framed in 1892; these I quote in full:—

London County Council.

"One-half at least of the total length of the boundaries of the site of any such premises which consist of an entire building, and in case of a room or other such premises not consisting of an entire building, one-half at least of the total length of the boundaries of the site of the building of which such room or other such premises form part, shall abut upon public thoroughfares, of which one thoroughfare at least shall be not less than 40 feet wide, and of the remainder none shall be less than 30 feet wide if a carriageway, or 20 feet wide if a footway.

"If, in compliance with Regulation No. 10, an additional passage or way should be necessary, it may be provided by means of a private passage or way.

"Such passage or way shall not be less than 10 feet in width, and under the complete control of the owner of such premises, and no doors windows, or other openings of the adjoining premises shall communicate therewith, or overlook any portion of such passage or way.

"Two separate exits, not leading into the same thoroughfare or way, shall be provided to every tier or floor of such premises.

"If any tier or floor shall be divided into two parts, two separate exits, not leading into the same thoroughfare or way, shall be provided to each of such parts."

Such exits shall be so arranged as to afford a ready means of egress from both sides of each tier or floor, and should lead directly into a thoroughfare or way.

"*New York City Building Laws.*

"Every such building shall have at least one front on the street, and in such front there shall be suitable means of entrance and exit for the audience. In addition to the aforesaid entrance and exit on the street, there shall be reserved for service, in case of

an emergency, an open court or space on the side not bordering on the street, where said building is ocated on a corner lot, and on both sides of said building, where there is but one frontage on the street. The width of such open court or courts shall be not less than 7 feet, when the seating capacity is not over 1,000 people; above 1,000, and not more than 1,800 people, 8 feet in width; and above 1,800 people, 10 feet in width.

"Said open court or courts shall begin on a line with or near the proscenium wall, and shall extend the length of the auditorium proper, to or near the wall separating the same from the entrance lobby or vestibule. A separate and distinct corridor shall continue to the street from each open court, through such superstructure as may be built on the street side of the auditorium, with continuous walls of brick or fireproof materials on each side the entire length of said corridor or corridors, and the ceiling and floors shall be fire-proof. Said corridor or corridors shall not be reduced in width to more than three feet less than the width of the open court or courts, and there shall be no projection in the same; the outer openings to be provided with doors or gates openings towards the street."

With regard to sites where neighbouring premises have doors or windows overlooking openings in the theatre, provision should be made to protect the windows in the theatres by iron hoppers, and the doors by sheet-iron linings. This precaution is to prevent the spread of fire from adjoining houses.

The Height of a Theatre as a Protection from Fire.

The restriction of the limit of the height of a theatre is next in importance to the surroundings, in reducing the fire risk and assisting fire extinction.

The majority of theatres that have been built within the last few years have been so planned as to place part of the structure below the level of the street. Limit should certainly be placed upon the depth to which the lowest part of a theatre should be situated below the pavement; with this desired limit, the system recommends itself as a good one, as it greatly curtails the height of the building, and also places the occupants of the various levels at more equalised distances from the street.

The Savoy Theatre may be quoted as a good example of this system; but a few steps lead to the pit, the dress circle is on a level with the street, the upper circle but a step or two above the pavement, and the gallery is approached by a very short staircase, as gallery staircases go.

For present consideration it may be asserted that a limit in height, obtained by placing the pit below the level of the street is a distinct advantage in preventing and extinguishing fire. There should, for the same reasons, be a restriction on the number of tiers, and this is insisted upon at St. Petersburg, where theatres must not contain more than four tiers in addition to the pit. In Italy the tiers are only permitted to be three in number.

The Division of a Theatre into parts by Brick Walls as a Preventative of Fire.

To prevent the spread of fire from one part of the building to another may almost be considered more important than provisions for extinguishing fire. The most perfect arrangements for extinguishing fire would be of far less use in a building constructed entirely in one risk, than in one divided into several fire risks by sound brick walls and solid fireproof floors.

A theatre ought to be so constructed that should a fire occur in any one part, the fire would burn itself out in that part, and not spread to other sections of the house. The following is what I consider is the most effective means of obtaining this condition of affairs. A theatre may be divided into four parts—(1) the workshops, (2) the stage, (3) the auditorium, (4) the approaches, which may again be subdivided into several parts, as rooms or shops for the various trades appertaining to theatrical business, scene docks, property rooms, the stage with its cellar, mezzanine, flies, gridiron, the auditorium with its tiers of boxes, galleries, corridors, passages, vestibules, saloons, cloak-rooms, &c., —it is useless here to try and complete the list.

Each of the larger divisions should be contained in solid brick party walls, passing through and above the roof, with as few openings in the walls as possible, and such openings should be closed and protected by doors, shutters, or curtains of fire-resisting materials.

Each of the sub-divisions should be constructed with brick walls, with floors and ceilings of concrete, in the case of the stage; only the floor of the stage need of necessity be of wood, the whole of the gridiron and flies could be constructed of iron. Much of the machinery at present made of wood could be of iron, and, in fact, be better adapted for the purposes of scenic display. The ropes for taking on and off the sliders could be made of steel.

The total separation of the workshops in

which the trades are carried on is most essential for the safety of a theatre, and such separation would in nowise interfere with the working of the house. Where large quantities of scenery are stored, they should be placed in a building quite apart from the theatre, but where the scenery that is in constant use is kept, the docks should be separated from the stage by brick walls, with openings closed by iron doors. The scenery in nightly use may be shifted into scene docks at the side or behind the stage. These scene docks, however, should not be used as permanent stores, but only for placing the scenery in, when shifting from one scene to another during the evening's performance. The same argument applies to property rooms.

The erection of a "proper brick proscenium wall," to divide the auditorium from the stage, has become a recognised necessity in theatrical buildings. The wall must pass through the roof, and be carried down to the level of the footings of the main buildings, in fact, be as substantial as an outside wall, with the large opening left for the proscenium. The wall must also pass under the stage, to divide the mezzanine of the stage from the orchestra. In addition to the large, or proscenium opening, there should be as few openings as possible in this wall. One is usually found at the stage level leading into the auditorium, and one beneath the stage leading into the orchestra. A theatre could be designed obviating even the necessity for these. Where openings do exist, they should be closed by self-closing doors of fire-resisting materials. The separation of the stage from the auditorium by a brick wall, with the smaller openings protected, but the large or proscenium opening left without fire-resisting curtain or shutter, would appear, even to the uninitiated, but taking half-measures for the prevention of spread of fire. The addition of a curtain, made of a material to check, if only for a time, the passage of smoke and flame from the stage to the auditorium, is undoubtedly a necessary provision in theatrical architecture.

Opinions differ greatly as to the nature of the material that should be employed for this curtain to fill the proscenium opening. The material must be such as to prevent or retard the passage of smoke or flame; one that will not feel the effect of the sudden changes of temperature from fire and water, and one that will resist the contact of falling bodies, such as timbers, scenery, &c. Iron will retard the passage of smoke, and for a certain time will keep back the spread of fire; but it will not withstand sudden changes of temperature. Wire-gauze curtains will not withstand the force of falling bodies. Certain forms of asbestos curtains will not bear their own weight, and become easily torn. Water and canvas curtains depend entirely upon the presence of the water to make them effectual for even a short period, and water curtains allow the passage of smoke. A curtain which appears to meet all requirements has been invented, the construction of which is described as follows:—"The protected iron curtains in an open framework of iron on wire, which is protected with a covering of silicate cotton, or slag wool, on each side; this silicate cotton is covered with wire netting, and forms an absolutely non-conducting material, and can be covered on the auditorium side with green baize, and so take the place of the old-established 'Green Curtain, or have painted canvas, and take the place of the 'Act drop.' The whole curtain is sufficiently pliable to adapt itself to any strain, and yet be perfectly fire and smoke proof. It can be raised by man power, by hydraulic power, by pneumatic pressure, or by other means found convenient. If desired, it can be lowered from any number of given points inside or outside the theatre." Other forms of curtain of equal merit exist, the detailed description of which is not wanted to increase my argument as to the need of such a provision.

The absolute necessity of the constant use of the fire curtain at every performance is obvious, in order that the lowering of the curtain may cause no feeling of alarm among the audience as well as to ensure the working order of the apparatus.

It is greatly to be wondered at that, for the prevention of the spread of fire in theatres, fire-resisting proscenium curtains were not insisted upon in London until the present year. In Paris a curtain of wire gauze must be provided to every theatre, the curtain must be hung with combustible cords and counter weights, suspended by metallic ropes, to check the rapidity of the descent. In Brussels and Hamburg metal curtains are insisted upon, and in St. Petersburgh a curtain of the required qualities has to be provided.

At first sight it would not appear that the size and proportions of the stage could have anything to do in minimising the risk from

fire, but in order to allow the scenery to be lifted up bodily, or to be moved off to either side of the stage, without being folded or rolled, the height from the stage floor to the gridiron should be twice the height of the proscenium opening, and the width of the stage from side wall to side wall, should be double that of the proscenium opening. By this provision the great risk of the canvas coming into contact with the hanging lights of the stage is avoided.

The introduction of the electric light on the stage has reduced this evil. Its use should be insisted upon as it is in Madrid. A very great risk from fire on the stage is thus prevented by the use of the electric light in lieu of gas for the purposes of illuminating the scenery; the danger arising from the gas among the canvas was the greatest that had to be contended against. Many theatres, however, are still lit by gas, The precautions of fireproof construction we have considered must not be overlooked because of the advantages of the electric light.

Having now considered the greatest divisions of a theatre with reference to the prevention of fire, it is necessary to pass on to the sub-divisions with the same object in view. In my former paper I dwelt upon the desirability of the provision of ample exits, the position in which they should be placed, the number of people that should use each exit, and such like details for the prevention of panic. I do not again propose to enter into this important branch of the subject.

The construction of the exit and entrance corridors, passage ways, and staircases should be entirely of fireproof materials, enclosed in, and supported upon solid brick walls, with floors and ceilings of portland cement concrete. A corridor of ample width should run round the back of each tier, divided from the auditorium by good brick walls, with means for closing the openings with either stout oak protected wooden or iron doors. By this precaution the audience would find a refuge immediately at the back of their seats, and the spread of fire from the auditorium to the exits would be retarded.

The construction of the tiers and galleries of most of our theatres erected within the past few years has shown great advancement towards perfecting theatre buildings. The cantalever system, and abolition of iron column supports to the various tiers, has a dual advantage, and the first that naturally asserts itself to the playgoer is the sighting of the house, the second and by far the most important is the additional fire-resisting qualities of the construction of the house under this system.

Until within quite recent times the tiers of the auditorium were universally constructed entirely of wood, with raking wooden stages supported upon unprotected iron columns. Where fire occurred, the columns gave way, and the falling timbers added fuel to the flames.

Tiers constructed on the cantalever system have no columns to collapse, but depend for their support entirely upon steel girders, and cantalevers embedded in concrete and supported by brickwork; upon this the "risers," or rows of seats, are built up, in concrete and iron, there is therefore nothing to burn.

The best kind of steps for staircases is one made of concrete faced with a hard wooden tread securely fastened to the face of the step. The steps should be "solid square" as distinguished from "spandril;" they should be cast with a light girder or rolled iron joist embedded in their length, to prevent fracture; the steps should be built into and supported by brick walls at both ends. Stone has been proved no fit material for the resistance of the flames, or the sudden changes of temperature caused by fire and water. It cracks under the influence of fire, and in cases of staircases, breaks short off where the steps are of "spandril" shape and supported only at one end. It is known that iron is also a material of little value in resisting fire; many examples of the manner in which it twists and collapses from the action of fire, are to be seen after fires in warehouses where floors are supported by columns and girders of unprotected iron.

Not only does the failure of iron to withstand the action of fire and water prohibit its use in an unprotected state, but also the fact that with its failure and collapse, other materials and the superstructure give way also. Iron must therefore be encased in some fire protecting substance, such as plaster, terra-cotta, or concrete, so as to prevent the direct action of fire and water upon it. Under these conditions iron is an acceptable agent in theatre construction.

Wooden beams, if used in great thickness and protected by plaster, would be quite admissible in theatre construction as far as fire-resisting qualities go; but their bulkiness would prohibit their use in modern buildings of this class. Heavy wooden girders have frequently been only charred in fires where naked iron girders and columns have entirely given way.

The roofs of theatres should be constructed of fireproof materials, to prevent fire spreading from any neighbouring building over-topping the theatre. For the same reason skylights should be covered on the outside with strong galvanised iron wire guards. In isolated buildings, the danger of spread of fire through the roof from surrounding property is abolished.

Living rooms should never be allowed in a theatre. The ordinary danger of fire arising from a domestic house is thereby added to the risks already existing.

In furnishing a theatre, due regard should be given to the one great object in view—not to add fuel to the flames. It is not necessary to detail here the furniture and fittings of a theatre that could be made of uninflammable materials, but one may mention, as examples, that frames of seats should be of iron, that plaster should be used, instead of wood, for decorative enrichments, and that the lighter fabrics should be periodically steeped in a fire-resisting solution. It is not so long ago that the internal fittings of a theatre were wooden partitions, matchboarded divisions, canvas screens, and such like inflammable construction.

Where light partitions or divisions are necessary, such as the separation of private boxes, these partitions should be formed of fire-resisting plaster upon iron frames and wire lathing.

Ventilation as a Preventative of Fire.

Perfect ventilation is admitted by all to be of the greatest importance in buildings of public entertainment, for the health and comfort of the audience, but I do not think it is often looked upon as a desideratum for the prevention of fire; yet, my experience teaches me that a well-ventilated theatre, with windows admitting plenty of daylight, is less likely to catch fire than a dark, stuffy house. Many bodies, when kept cool, are incombustible, but when constantly subjected to a high temperature, become highly inflammable; more especially is this apparent in that portion of a theatre called the dome—that is, the space over the auditorium ceiling, which used, at one time, to be the favourite position for the carpenter's shop. When this part of the house was built of wood, the timber, in time, became little better than tinder, ready to flare up on contact with the slightest spark. The same state of affairs was frequently to be found in the gridiron, and among the roof trusses over the stage; here, where no ventilation or light was admitted, dry dust collected, and the excessive heat from the hundreds of lights of the stage below, which gathered among the timbers, created a condition of things terrible to contemplate.

Advancement in the science of building has prevented the probability of fires in the roof of a theatre, the space over the "dome" is seldom used, and concrete roofs and ceilings, proscenium walls, ventilation and daylight, have reduced the risk to a minimum.

Efficient ventilation, constantly changing the air, to keep the house at an even temperature, is what must be acquired. The ventilation of the stage requires great care. There must be no down draughts to move about the flats, cloths, or wings among the gas battens and side lights; the system must be one of extraction at a high level, and admission at a low level. By ample ventilation the danger of asphyxia in cases of fire is guarded against.

Daylight and cleanliness, I have said, are essential for the prevention of fire. Where ample daylight is admitted, there is every chance of the theatre being swept and kept clean in every corner; collections of rubbish, dirt, and dust, in out-of-the-way nooks and corners, are always a source of danger. Dry dust, paper, shavings, oil-rags, and such like inflammable refuse, ready to ignite by spark or spontaneous combustion, are often found swept away out of sight by the cleaners. Such carelessness and thoughtlessness are too often the cause of fire. The use of matches, the burning ends of cigars or cigarettes, recklessly thrown among those dangerous little heaps of rubbish, is sufficient to start a fire which may end in dreadful results and loss of life. Carelessness among the scene-shifters, the gasmen, the electric light men, on the stage, in the dressing-rooms, or workshops, must be ever guarded against. The use of firearms, fireworks, and coloured fires should be carefully watched by the fireman in charge. The upsetting of oil-lamps, explosion of limelight bags, the existence of foul gas burners, are all sources of danger. Among other causes of fire to which a theatre is subject, I cannot speak too strongly of the great danger of carrying on various trades in a theatre, or in workshops in the same risk as the theatre. I have already said that the structural separation should be strong party-walls and fireproof floors, and the reasons for this are not far to seek. The trades appertaining to a theatre necessitate the employment of light and highly inflammable materials. The stage carpenters' work is of

a thin and flimsy character; the property-makers' "props" are mostly of wood and paper; the wardrobe-makers' stores are fitted with highly inflammable substances; the scene-painters' room contains little but combustible materials, and the scene docks are crammed full of flats, scenery, cloths, and "props," as dry as tinder. The engine-room, electric light shed, dynamo room and furnace chamber are all adjuncts of the modern theatre, which, if not separated from the theatre, add greatly to the risks of fire.

The importance of placing all trades in rooms specially built for the purpose requires no further explanation, when the prevention and extinction of fire is under consideration. It is not necessary now to speak in much detail of causes of fire arising from defective gas servive, or electric light supply; suffice it to say that gas meters should be placed in proper brick ventilated, brick built chambers, with a ceiling of concrete and the opening closed by an iron door, and that gas brackets should not be jointed, nor pendants of a telescope pattern. Gas pipes must be of hard metal, the sun burner and fitting constantly cleaned, and a proper gas plate provided on the "prompt" side of the stage.

The special system of warming theatres requires most careful study. The authorities of different countries insist upon different methods of warming public buildings. Paris demands that no theatre may be warmed except by air gratings, the furnaces for which must be placed in the basement. Brussels leaves the system open to choice, but compels the apparatus to be non-explosive, and placed in a vault separated from the rest of the building by double doors. In London the furnace room must be in a separate building, entered directly from the street, with a large open grille for the escape of steam. In St. Petersburg, the only method to be employed is steam or hot water, and, in Berlin, where hot air is enforced, the gratings must be protected by wire netting of close mesh, and no objects of an inflammable nature are allowed near the grating. Where hot air is used, the conduits must be constructed of iron or of earthenware, 2½ inches thick, including the coating. Where hot water is the heating power, the apparatus should be of the low-pressure system.

Open fireplaces are objectionable in most parts of a theatre, but where they are necessary, they should be protected by fixed iron wire-guards, with a door left to open for the purposes of cleaning the grate. On no account should open fireplaces be allowed in any part of the stage, workshops, scene docks, or stores. Where closed stoves are used, they should be earthenware. Stores should not be heated at all.

Special care must be given to the building of the flues and chimney stacks, which should be kept clean and periodically swept.

At the risk of again repeating myself, I will now enumerate some of the causes of theatre fires, with the object of making provision to prevent fires in theatres.

1. Not dividing the various sections and sub-sections by proper brick walls and fireproof floor and ceilings.
2. The use of inappropriate building materials.
3. Bad, faulty, or scamped construction.
4. Inflammable fittings, finishings, and furniture.
5. Dangers arising from the proximity of surrounding premises.
6. The misuse of portions of the premises; living on the premises.
7. Dirt and darkness, non-removal of trade refuse.
8. Excessive heat and want of proper ventilation.
9. Open and unprotected fire-places, faulty flues.
10. Imperfect gas system, faulty installation of electric light.
11. Use of matches, naked lights, spirit lamps.
12. Imperfect warming apparatus,
13. Smoking in parts of the theatre not specially adapted and fitted for the purpose.
14. Lighting, spontaneous combustion, incendiarism.
15. Want of proper fire appliances.

To extinguish fires in theatres there is only one practical and reliable system. The proper use of water in conjunction with proper fire appliances. One of the most effective fire appliances is the common fire-bucket. These should be hung in large numbers in all parts of the theatre, on the walls just above the heads of the audience. They should be filled with water at all times, a bucket of water judiciously used at the outbreak of fire will save thousands of pounds' worth of property, and perhaps hundreds of lives.

If the fire is not discovered in its first stages, the water must be played upon it with some degree of force. Then the various forms of portable engines, corridor engines, hand-

pumps, chemical engines, extincteurs, &c., are necessary. When the fire attains serious proportions, the hydrants must be brought into play, and be followed by the brigade engine and the brigade. Provision for all these appliances must therefore be made in all sections of the house, with all fittings, tools, &c., required by a fireman. The employment of trained firemen, as constant day and night watchmen, is the duty of every manager having the safety of the public in his hands. It should be the duty of these men to attend to all the appliances and the fire curtain, and to turn off the gas from the main at the outbreak of fire; a provision of safety which calls for the subsidiary lighting of the passages, staircases, and corridors by oil lamps, or composite candle lamps.

On the stage should be kept wet blankets, hatchets, axes, reaping hooks, to cut away the scenery.

The materials used upon the stage should all be periodically saturated and coated with such substances as would impart fire-resisting qualities.

One word as to water supply. Tanks are not to be relied upon, they are too often empty or only half full when most needed. The water supply to the hydrants should be on the high pressure constant supply, and be obtained direct from the main.

The theatre should be in telegraphic and telephonic communication with the nearest fire brigade station, and outside balconies with escape ladders should be provided to all parts of the theatre, as means of escape and for the use of the firemen.

In writing the above I have not lost sight of the desire of the Council of the Society of Arts to obtain an invention for the prevention and extinction of fire, but, with a somewhat wide experience of theatre construction before me, it has been my earnest desire to lay before the Council the many risks in and about a theatre with which no invention would effectually cope, unless assisted by a judiciously planned and well-built house situated on a suitable site, and well managed. Such inventions for extinguishing fire as require the very presence of the enemy to start them into action cannot be too strongly condemned; water sprays and sprinklers set into action by the melting of solder may start, through excessive heat, when not required, and will do more harm than good, and perhaps cause alarm and panic. Everything in a theatre, to be effectual, must be in constant use. The employment of sprinklers over the stage, on the non-automatic system, is undoubtedly an advantage, as by them the whole of the scenery can be instantly wetted. It is thought by some that the fitting up of patent appliances and inventions in old and ill-constructed theatres will render them safe, but to the initiated the fallacy of this is apparent. Such appliances are good servants, but they will never become the masters of large fires.

THE SALT INDUSTRY OF TRIPOLI.

In Tripoli the salt industry is a State monopoly, and in that country there are sixteen large salt-works—one at Tadjoura, two at Lavia, six at Misurata, five at Bengazi, and one at Derna. M. G. Vadala, Belgian Consul in Tripoli, says that the most important of these are the Brega, Tadjoura, and Bengazi works. As regards the Brega salt lake, situated on the western confines of Tripoli, and separated from the sea by a strip of land, not much more than half a mile in extent, this spreads its waters, in winter, over a territory exceeding 500 square kilometres, or 190 square miles; and this is the more remarkable as, in Europe, the largest and finest salt marshes—those of Italy and Spain—do not cover an area of more than 200 to 250 hectares (hectare = 2·47 acres). This marsh can supply, to any extent, salt of the very finest quality, well crystallised, and excellent for use in preserving meat and fish, and in this respect it can compare very favourably with salt of European production. The extraction of the salt can be commenced in June and continue until the rainy season in November, and in this period of five or six months as much salt as may be considered necessary can be conveyed to the sea, and is ready at any time for shipment. The roadstead of Brega is accessible at all seasons, and ships can always find a safe anchorage there, although they are obliged, on account of the shallow water, to anchor at some considerable distance from the shore. M. Vadala says that, in spite of the advantages offered and the benefits that would accrue to the Ottoman Empire and to other countries as well from the sale of the product, this salt marsh remains practically unworked. Situated in the immediate vicinity of Tripoli the small salt marsh of Tadjoura is, like almost all the African works, a natural marsh, of which the extent measures a little more than a kilometre (kilometre = ·621 of a mile) in length, from north to south, and about 800 yards in width, from east to west. A strip of land, between 600 and 700 yards in extent, separates it from the Mediterranean coast. The rains alone feed the Tadjoura marsh, and, from the commencement of April, the water is so regulated, according to the direction of the wind, as to concentrate it in a given spot to receive the salt deposit. This is done by

building up dams with the soil taken from the marsh itself, which is turned up on the borders of the trenches dug, and this operation is repeated until the water is collected in an internal basin, which does not represent more than a fifth of the total superficies of the marsh, and has a depth varying from 6 to 20 centimetres. This preliminary operation is indispensable, in order to prevent a frequent scattering of the liquid, and a rapid evaporation of a water which, having too shallow a depth, would only produce a glutinous salt, and of a nature difficult and expensive to collect. This work of concentration being effected, nature itself will do the rest. It is generally towards the end of May or beginning of June that the first symptoms of crystallisation are found at the approaches of the dam. During 30 or 40 days of constant evaporation the salt is deposited: it accumulates at the bottom of the basin, and forms a bed, which, in the most productive places, rarely exceeds a centimetre in thickness. This crystallisation is only complete towards the end of June, and it is at this time that the extraction of the salt usually takes place. The length of time that this operation lasts varies between 30 and 50 days. The salt, when collected, is carried in boats to the warehouses at Tripoli. All these different operations, from the formation of the dams to the warehousing at Tripoli, bring the cost price of the salt up to 10 francs the ton, when the yield exceeds 1,000,000 kilogrammes, but which reaches 15 francs a ton when this yield remains below 60,000 kilogrammes. The Tadjoura salt is either consumed in the city of Tripoli or sent to the Turkish markets, and the price realised is about 90 francs the ton. As regards the Bengazi salines, the most important is that situated at Sidi Hussein. This measures 13,000 metres long by 900 wide, its area, therefore, being about 120 hectares. The Juliana marsh is a little longer, but less wide. From the former, as much as 30,000 tons have been obtained, while the yield of the latter has never exceeded 1,000 tons. Each marsh is fed by sea-water, and the crystallisation, which commences in the beginning of July, is not complete until the end of August or the early part of September, and it is at this period that the extraction and transport of the salt is effected. The operation of raising the salt only finishes with the first rains, which occur generally towards the end of October, so that only about 50 days work can be counted upon. The Bengazi salt is affected by a certain bitterness, which only disappears a long time after its extraction, and has the effect of temporarily depreciating it in value.

FISHERIES OF THE SEA OF AZOV.

The British Vice-Consul at Kertch says that the fishing season, and particularly the herring fishing, of the close of the year 1891 was one of the best on record. Over 10,000,000 herrings, valued at more than £300,000, were landed by the Kertch Straits and Kertch out-bay fisheries; while sturgeon and other kinds of fish have produced another £20,000 for the same period. The Sea of Azov, with the deltas of two large rivers—the Don and the Kuban—falling into it, and only a comparatively narrow outlet at Kertch Straits, forms one of the most renowned natural fishing reservoirs of Europe. Vice-Consul Hunt says it would require a naturalist to give a complete list of fresh-water fish that abound all over it, and he only mentions the most important in commerce on account of the enormous quantities that are caught. For example, the carp, the Russian *taran* (*Cyprinus vimba*), and particularly the *soudak*. This last, fit for any table when fresh, is cured, salted, and sun-dried in enormous quantities. The greatest wealth and importance, however, is centred in what is called by the Russians, "red fish," and the caviare factories that depend upon it. Under the general name of red fish, Russians include different varieties of sturgeon, the principal being *Accipenser Sturio*, *L. Accipenser Stellatus*, and the *Accipenser Huso*. The most esteemed for its flavour and for caviare is the first, and the largest in size is the last, some of which of 700 lbs. weight are not uncommon, and in rare instances specimens up to 3,000 lbs. weight have been caught in the Azov. Some approximate idea of the abundance of fish may be formed in considering that caviare—the indispensable luxury to a Russian — is simply the destruction of milliards of sturgeon roes, and has been so from remote times. Still, only of late a perceptible diminution in sturgeon fisheries has been felt. A small quantity of herrings is caught in the Azov, as ice there prevents work on any remunerative scale, and it is only during the migration of this fish from the Azov to the Black Sea during November and December, and its return soon after the ice begins to clear, that these are caught in the Kertch Straits and the out-bay. It would be imagined that, with such a source of wealth, the fishing fleet would be an important one, but nothing of the kind, in the English sense, exists. Fishing craft are invariably open boats, as the method adopted for out-coast fishing is as primitive as barbarously destructive. The sturgeon fishing is managed by hook lines; these lines are, in fact, pretty strong ropes, from which strong and sharp hooks hang at a distance of less than a foot from each other some three or four feet below the surface of the water. One of these ropes may contain from 800 to 1,000 hooks, and, when stretched in the water, is supported by bark floaters, the ends being strongly anchored to resist the force of such powerful fish as the sturgeon; such lengths of rope are connected together so as to form one line of many thousands of hooks. There are thousands of these engines of destruction used in the Sea of Azov, and it is computed that 10 per cent., at least, of the fish tear themselves from the hook, and are carried away by the current to float afterwards in a putrid state as

a prey to birds and other fish. Fresh-water fish is generally caught by hooks in the many estuaries of the rivers, and only the herring is caught by seines and nets. The former are of enormous size, worked by gangs of thirty to forty men; the latter are only worked by individuals in small boats close to the shore. Not a single trawler exists, and salt-water fishing along the Crimean coast, except close to towns, for the local market, is absolutely unknown.

Correspondence.

THE EXTENSION OF COLONIAL TRADE.

In reference to Colonel Howard Vincent's paper I previously endeavoured to point out the true bounds of free trade, which occupies so prominent a place in this discussion, and also its relations as a doctrine of economical science. I showed that valuable as free trade is theoretically, the measure of it we have had and have called free trade has not been the sole or chief cause of the expansion of the industry of this country, and of the world at large. It is only one influence in conjunction with many great causes in operation which in our time have so enormously operated on the world.

We have, consequently, duly to regard the consideration of free trade as a factor, neither undervaluing it, nor setting it aside, neither supposing that nothing else is to be discussed, or taken into account, or adopted, in providing for our own trade, our colonial or our foreign trades.

In my letter I, called attention to the necessity of keeping in mind the true bounds of economic science, or political economy as it is commonly called, and of not overstraining its functions, and particularly with regard to political science. Although we hear so much of economic science, and we have so many professors of it, and adepts in it, and it is proposed to be taught in Board schools to boys and girls, there is no society for the discussion of it as of other sciences, abundant as are societies in London, for we cannot include the peripatetic reunion of the British Association. In Paris, there is a large and well-known society. What there is here is the Political Economy Club, which has done some very good work, but is a limited private dining clnb. The Statistical Society is generally supposed to be the society for economic science, and many of its papers belong to that domain, but it has rejected economic science as a function, many of its strait-laced members believing that "the numerical method," to which by its foundation it was devoted, is the only legitimate application of its meetings and its journal.

Two years ago, a society was formed for the publication of a Journal of Economic Science, but it did not accept the public reading and discussion of papers.

There is no society for political science, and it is only recently that the Royal Historical Society has entered on its functions. It may be noticed that already, under the care of the Rev. W. Cunningham, D.D., it has devoted attention to the historical investigation of economic subjects.

The result of all this is an anomalous state of affairs. The theoretical side of economic science is more studied than the practical, and its public representation is more in the hands of the theorists and schoolmen, than of merchants, and bankers, and men of business.

So far as the latter are concerned, they have always been known for their attachment to free trade, as the *Spectator* defines Sir Andrew Freeport to have been, and the history of economics illustrates this. Of course it is commonly imagined that Adam Smith was the inventor of economic science and of free trade—if Richard Cobden was not—but the English school of the science existed before Smith, as we see in the scores of works reprinted under the auspices of Lord Overstone. To Adam Smith we are indebted for popularising the labors of so many able men, and for throwing great light upon them. In the eyes of the public, however, he has swallowed up their reputations, and become an accepted apostle. This has in the scientific world been limited by the teachings of so many eminent writers, as Ricardo, Malthus, the Mills, and others. Nevertheless, the supposed inheritors of Smith have claimed the inheritance in his name.

The result has been that the independent public have been ousted. If anyone has got up and stated a fact or an opinion not in accordance with the imaginary canons of free trade, he has been set down at once as an ignoramus, an abetter of fair trade and of protection, and an enemy of the country. He has been very lucky if he has not been denounced in several newspapers. It is very true that the fair traders have largely contributed to bring this fate on themselves, for instead of taking measures to obtain free discussion, they have only instituted societies for the promulgation of their own nostrums.

One aspect of the matter has appeared strange, if not ludicrous in the eyes of sober observers. Here the Cobden Club has become supreme, and the apotheosis has been complete of a most fallible man, whose doctrines and whose prophecies are daily brought to nought. Weak minds cannot do without masters and authorities, though they can do without truth. Throughout the numbers of a hundred millions of English speaking men, in the other England and the Colonies, protection has extended, and so in most countries of the continent. Of course no movement can take place among the body of our people without influencing us here, and protectionism has long since been advancing and gaining adherents. Statesmen have seen this, but they have not dared to take an open course, they have protested their adhesion to the fetish of free trade, and have not dared to avow their convictions that unless some

change in our policy is adopted ruin may befall the country.

It is scarcely complimentary to public men that they have allowed themselves to be beguiled by the confusion of their ideas, and to be led away from correct conclusions by statistics fallacious in their application. The amount of mischief which has been done has been very great. In our Colonies working men, many of them assisted emigrants, have been instigated, not only to deprive our countrymen here of their share in the Colonies, but to promote artificial industries against the national welfare.

The sooner the matter is carefully and calmly discussed, and put on a right footing, the better it is for the interests, it may be said, the healthful existence, of the Mother Country and the Colonies. Mr. Mundella, on one occasion, made a most striking observation at the Statistical Society. He had just returned from the United States, and, in reference to some free trade observations which had just been made, he said he did not know how it was that arguments, which appeared to us to be so convincing, had no effect on men equally intelligent among our American brethren. That is the real representation of the controversy; and we have got to come to a right understanding and application of the facts, the figures, and the doctrines.

HYDE CLARKE.

32, St. George's-square, S.W.,
20th June, 1892.

BRITISH SHIPBUILDERS AND THE CHICAGO EXHIBITION.

Mr. McCormick under this head refers to the fact that while the export of iron and steel manufactures from Great Britain fell off 21 per cent. in the year 1891, that in Germany increased 19 per cent.

This is a matter in which I take considerable interest, viz., "the transfer of trade from British to German workshops," as Mr. McCormick very correctly calls it, but I fear that exhibiting at Chicago is but one iota of what we must do to recover the prestige which we are losing if it is not already lost.

It is not want of capability that has brought about the present state of affairs: it is the British workman's ignorance of the conditions of the foreign labour market that is the partial cause. British strikes founded the Belgian iron industry, and before long will have founded the German industries on such a firm basis that Englishmen can no longer even compete with them.

Then, again, the British manufacturer must learn to supply his customers with what they require, as the Germans do, and not thrust something else on them because it is what he is in the habit of making.

When he has learnt to do this, and to issue catalogues in the language and units of the market he seeks to supply, and has, above all, secured the co-operation of his workmen, the good old times will return, and the British manufacturer will be in a position to defy the world to compete with him.

I pen these lines not as a mere fad, but as the results of a convincing experience abroad.

HENRY W. HANDCOCK.

121, Cannon-street, E.C.
July 4, 1892.

General Notes.

GREENWICH TIME IN BELGIUM.—It has been announced in the *Moniteur Belge* that Greenwich time will in future be adopted in Belgium. The *Board of Trade Journal* reports that Mr. M. Gosselin, her Majesty's Charge d'Affaires at Brussels, in a despatch to the Foreign-office, dated the 1st May, has transmitted a copy of a Bill and explanatory statement for the adoption of Greenwich time in Belgium, and reports that the Bill has been passed and has received the Royal assent.

ARTIFICIAL PRODUCTION OF PRECIOUS STONES.—A paper on this subject by Messrs. Fremy and Feil, was printed in the *Journal*, in 1878, vol. xxvi., p. 304. A late number of the *Glasgow Herald* contains an account of some experiments in the production of gems by Mr. James Morris. It is stated that the bulk of the gems obtained are white, or rather colourless sapphires, and it is affirmed that they are hard, infusible at all ordinary attainable temperatures, and insoluble in any acid. It is further stated that by subsequent treatment some of them have taken on the sapphire blue.

BARCELONA EXHIBITION.—As a complement to the National Exhibition of Artistic Industries to be held next September in Barcelona, the Common Council of the City of Barcelona have resolved to institute an international section of reproductions from the artistic industries of all ages till 1815, in which may be exhibited the most remarkable specimens that the sumptuary arts of all ages and all countries have produced from the earliest times till the beginning of our century. The works to be exhibited in the section of reproductions must be delivered at the offices of the Secretary of the Exhibition (Paseo de Pujades, Barcelona) before the first of September next.

The Telegraphic Address of the Society of Arts, and of the Royal Commission for the Chicago Exhibition, is "Praxiteles, London."

No. 2,069. Vol. XL.

FRIDAY, JULY 15, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Chicago Exhibition, 1893.

MEETING OF THE ROYAL COMMISSION.

A meeting of the Royal Commission was held on Wednesday, 13th July. Present: The Attorney-General, M.P., in the chair; Sir Frederick Bramwell, Bart., D.C.L., F.R.S., Sir Frederick Abel, K.C.B., D.C.L., D.Sc., F.R.S., Sir George Birdwood, K.C.I.E., C.S.I., LL.D., M.D., Major-General Sir Owen Tudor Burne, K.C.S.I., C.I.E., Alfred Carpmael, R. Brudenell Carter, F.R.C.S., Sir George Hayter Chubb, B. Francis Cobb, Sir Philip Cunliffe-Owen, K.C.B., K.C.M.G., C.I.E., Professor James Dewar, M.A., F.R.S., Sir Henry Doulton, James Dredge, Sir Douglas Galton, K.C.B., D.C.L., F.R.S., Walter H. Harris, John Biddulph Martin, William Henry Preece, F.R.S., Sir Albert K. Rollit, M.P., and Sir Owen Roberts, M.A., F.S.A.

EXECUTIVE COMMITTEE.

A meeting of the Executive Committee was held on Wednesday, 13th inst. Present: The Attorney-General, M.P., in the chair; Sir Frederick Abel, K.C.B., D.C.L., D.Sc., F.R.S., Sir Frederick Bramwell, Bart., D.C.L., F.R.S., Alfred Carpmael, B. Francis Cobb, Sir Philip Cunliffe-Owen, K.C.B., K.C.M.G., C.I.E., Sir Douglas Galton, K.C.B., D.C.L., F.R.S., John Biddulph Martin, and Sir Owen Roberts, M.A., F.S.A.

TRANSPORTATION COMMITTEE.

A meeting of the Transportation Committee was held on Thursday, 7th inst. Present: Professor Elgar, LL.D., in the chair; Sir Nathaniel Barnaby, K C.B., C. V. Boys, F.R.S., Francis Cobb, James Dredge, George N. Hooper.

IMPORTATION OF LIVE STOCK.

The following circular letter respecting the importation of live stock for exhibition at the World's Columbian Exposition has been received:—

1892.
Department No. 95.
Division of Customs.

Treasury Department,
Office of the Secretary,
Washington, D.C.,
June 18, 1892.

To Collectors and other Officers of the Customs.

The following regulations will be observed upon the entry of animals imported for exhibition at the World's Columbian Exposition at Chicago:—

1. Entry will be made at the Custom-house according to the forms prescribed in Articles 4, 6, 7, and 9 of the Special Regulations issued by this Department on November 5th, 1891.

2. Accompanying the prescribed invoice there shall be filed with the collector such a description of each animal—by distinguishing marks and characteristics—as shall identify the same when withdrawn from the Exposition for sale or export.

3. In order to avoid any risk from delay, entry of such animals may be made and completed in advance of the arrival of the vessel of importation, except that the permit will be withheld by the collector for delivery to the importer or his agent on the announcement of such arrival.

4. The Government will not be responsible for the security or safe keeping of such animals. The transfer to the transportation line will be made under the supervision of the collector at the port of arrival.

5. On arrival at the Exposition the animals will be subject to such disposition as may be agreed upon between the authorities of the Exposition and the Collector of Customs.

6. So far as applicable, the regulations of November 5, 1891, will govern importations of animals, and at the close of the Exposition imported animals on exhibition may be withdrawn for consumption, transportation in bond, or exportation under Article 20 of said regulations; but animals not so withdrawn will be sold at auction, and the proceeds, after deducting duties and charges, will be held subject to the order of the owner or importer.

7. These regulations will go into immediate effect.

O. L. Spaulding,
Acting Secretary.

ARRANGEMENTS FOR FOREIGN EXHIBITS.

The following is from the *Chicago Tribune*, June 30th, 1892:—

After months of discussion between Treasury officials, World's Fair managers, and Custom-house agents, the Treasury Department has accepted Collector Clark's plan for caring for foreign exhibits

and merchandise intended for display or sale at the World's Fair. The plan is simple, but it is believed will be a successful one, and lacks the annoying and complicated features of the system established at the Philadelphia Centennial.

The system contemplates two classes of goods which will be received into the Exposition grounds. The first class will be goods for exhibition purposes exclusively, and when so marked and accepted by the Exposition management, will be in the absolute control of Government inspectors, whose duties will be to see that not the slightest article put on exhibition is sold or released until after the Fair is over. This rule regarding exhibits will be rigidly enforced, and if any one, by mistake or otherwise, enters for exhibition purposes more goods than he intended, he will have no remedy, and must allow the goods to remain on exhibition until the Exposition is closed. However, there will be probably little trouble on this point, as the Exposition officials will pass upon all goods which enter the grounds and give official notice of all articles they accept.

The second class of foreign goods which will be allowed to enter the grounds is classed as merchandise. Goods of this class will be for sale and not exhibition alone. All these goods will be stored in bonded warehouses on the grounds when received. After they are stored, if the management desires to use any of the merchandise for exhibition purposes, it can do so by marking the goods in accordance with the regulations. All other merchandise, however, when taken out of bond for sale, must pay the regular duties assessed on such goods at the Custom-house.

Traffic Manager Jaycox had a lengthy interview with Collector Clark yesterday regarding the regulations just adopted. It was decided that the regulations and all other necessary information about the system of handling goods at the World's Fair Custom-house should be printed and sent abroad for the benefit of foreign merchants, in order that no confusion may arise upon the receipt of goods at the port of entry. Information as to the railroads over which bonded goods could be brought will also be sent abroad. Collector Clark believes that the regulations as adopted will not be at all burdensome upon exhibitors, while at the same time they will protect the Government in all its rights, and leave no loopholes for frauds.

PRICING OF EXHIBITS.

The following is from the *Chicago Times* of July 1, 1892 :—

The publication by *The* [Chicago] *Times* of the letter issued by Director-General Davis, making an arbitrary ruling in regard to the placarding of exhibits, has resulted in calling the attention of the Director-General to the *faux pas* made by his office, and he has asked for a withdrawal of the letter. It appeared that the greater part of the error was made by the State Department at Washington in duplicating a letter intended for one individual, and sending it as a circular to all United States consuls.

The text of the Director-General's letter is as follows :—

"Chicago, Ill.,
"June 29th.

"*To the Honorable the Secretary of State, Washington, D.C.*

"SIR,—The publication in England of the letter which I had the honour to address the department under date of March 11th, 1892, in reply to the inquiries of Consul Augier, of Feb. 15th, 1892, in behalf of certain woollen manufactures of Rheims, has led to the inquiry from British manufacturers whether my letter was intended to revoke the permission previously given to foreign manufacturers to placard their exhibits with the prices at which they will be sold in bond.

"The paragraph in my letter of March 11, 1892, which refuses permission to the manufacturers of Rheims to placard their prices as requested in the letter of Consul Augier was a mistake, and I desire, therefore, to have that letter revoked by authority of the department, and the following statement sent out to Consular officers as the correct ruling in the case :—

"'Foreign exhibitors in the World's Columbian Exposition will be permitted to state upon placards attached to their exhibits the price at which said products will be sold at the place of manufacture, and also the prices in bond and out of bond, or exclusive and inclusive of the Customs duties in Chicago.'

"Asking that the same publicity be given by the department to this correction as was given to my letter of March 11, I have the honour to be, very respectfully yours,

"GEORGE R. DAVIS,
"Director-General."

Proceedings of the Society.

CANTOR LECTURES.

MINE SURVEYING.

By BENNETT H. BROUGH,
Assoc.R.S.M., F.G.S.

Lecture I.—Delivered March 28, 1892.

When we consider the enormous value of mineral resources, the high importance, from a commercial point of view, of the art of mining is apparent. In this country alone, the value of minerals raised in one year has approached £80,000,000, the result of the labour of over 500,000 persons directly em-

ployed in their extraction. Last year, in the United Kingdom, the production of one mineral, coal, amounted to 185,500,000 tons, and the vast sums representing the British capital invested in all parts of the world will be readily appreciated by you all. It follows, therefore, that it is a matter of importance that the extent and character of mineral deposits should be made known. And this can only be effected by careful and accurate surveys.

The execution of such surveys is frequently a matter of considerable complication, on account of the great depths that are now attained by mining undertakings. The Ashton Moss Colliery, for example, has a shaft, the deepest in the United Kingdom, 2,880 feet in depth, and at the bottom of the workings of that mine the depth of 3,105 feet is reached. The deepest shaft in the world, the Maria shaft, at the Przibram silver-lead mines in Bohemia, is now 3,650 feet in depth. And as the task of the mine surveyor is not only to make an accurate survey of the underground workings and of the surface of the mine-royalty or concession, but also to connect the two, you will readily see that depths such as these render his task an extremely difficult one.

In this course of lectures I hope to be able to show you some of the difficulties the mine-surveyor has to contend with, and to explain to you the manner in which these difficulties are, and have been, overcome. But before passing to the subject of mine-surveying proper, it would perhaps be well for me to explain some of the terms that I shall have occasion to employ in relation to mineral deposits.

All mineral deposits are divided into three broad divisions. The first includes the beds or seams, such as those of coal, of iron ore, and of salt. These are deposits laid out more or less horizontally and parallel to the stratification of the surrounding rocks. In some cases, the beds may occur at the surface; for example, where the mineral is found in gravel, sand, or other alluvial deposits, as in the gold placers of California, and in the now exhausted tin streamworks of Cornwall. Other examples of superficial deposits are afforded by the bog iron ores of various localities. In other cases, the mineral occurs in seams interpolated between rocks of sedimentary origin, as in the case of coal and ironstone, and in that of the cupriferous shale of Mansfeld, in Prussian Saxony, a seam some 5 inches in thickness, that has been worked since the 12th century. The second class includes mineral veins or lodes, which are tabular masses differing in character from the enclosing rocks; a lode being usually defined as a repository of mineral matter, which fills more or less completely a former fissure in the earth's surface. Lastly, the deposits of the third class consist of detached masses, which cannot be considered as beds or as lodes. Such, for instance, are the red hæmatite deposits of Ulverston, the brown hæmatite deposits of the Forest of Dean, and the iron mountains of Gellivara and Taberg in Sweden, and of Missouri in the United States.

The simplest classification of mineral deposits is that based on their form, into two divisions:—(1) Tabular deposits, a class subdivided into (*a*) beds, whether interstratified or superficial, and (*b*) veins or lodes; and (2) non-tabular deposits or masses. In consequence of these differences in form, various methods of working have to be employed. In the case of coal and similar bedded deposits, the actual modes of working, although varying greatly in every district, may be broadly divided into (I.) the pillar and stall method, where the first stage of excavation is accomplished with the roof supported by pillars of coal; and (II.) the long-wall method, where the whole of the roof is allowed to settle behind the miners, no sustaining pillars being left. The latter method, when well planned, is the better as regards facility of ventilation. There is, too, less liability to accidents from falls, and the work of the surveyor is much simplified.

The mode of working mineral veins, which are usually highly inclined, differs greatly from that followed in the case of the more or less horizontal beds or seams. Horizontal galleries, termed levels, are driven upon the vein, usually 10 fathoms (60 feet) apart. These are connected by means of small shafts termed winzes. Projected on a vertical plane, the vein will thus be seen to be cut up into pillars, and to resemble the appearance in plan of a colliery worked by the pillar and stall method. These pillars are usually worked away by miners, standing on timber platforms, breaking down the mineral above them.

The first necessity of every well-managed mine is an accurate plan of the underground workings. This is almost as important to the safety of human life as efficient ventilation. At the present time, it is true, few large mines are conducted without a satisfactory plan; but there are still many mines in which mine-surveying is much neglected. The plans are

laid down without any reference to the phenomenon of the variation of the magnetic needle, and, trusting to old plans constructed in this way, the miner may drive straight into old workings filled with water, the tapping of which would be death to all employed in the mine. Many companies adopt the short-sighted policy of grudging the moderate sums required for the employment of qualified surveyors, and leave the plans and surveys in the hands of men already overtasked with other duties. The cost of mine surveys, it may be noted, is trifling. In Westphalia, for example, where the colliery plans are laid down with excessive accuracy, the annual expenditure on plans and surveys has been calculated to be 8¾d. for every 100 tons of coal raised, or 2s. 1d. for each workman employed.

Cases are known in which millions of tons of the finest coal have been lost, simply because the officials had no accurate plans to guide them in their work. In many cases, the pillars have been found to be many times larger than there was any necessity for, or to be so small as to be entirely worthless. The importance of knowing the exact size of all pillars, and the exact height of the strata above the coal, cannot be over-estimated. In short, accurate plans mean greater safety and increased profits.

As examples of errors in surveying involving great loss, danger, and future grave embarassments, numerous cases might be cited. Thus, at an important mine in Spain, an incorrect survey caused an error of 65 yards to be made in driving a main tunnel 200 yards in length; and at a mine on the sea-coast of Cornwall, a level, thought to be straight, finally emerged from the cliff some distance above the point of entrance. Again, at a mine in California, a shaft was sunk, and a 2,000-foot adit-level run in from a point below. It was desired to connect these, and the owners drove in various directions for nearly two years without success. Finally, a surveyor contracted to do it for $2,000. After a careful survey, he and his son set to work, and made the connection in two days. The importance of keeping an accurate section of a mine was shown by a fatal accident which recently occurred in North Wales. Water unexpectedly broke into a shaft in progress from an old shaft shown on the section to be 40 feet away; but in reality the thickness of the barrier, measured by Professor Le Neve Foster, H.M. Inspector of Mines for the district, was only nine feet. Here, without doubt, the loss of the miners' lives was due to the want of a correct survey.

In collieries, too, examples are not wanting. Thus in one case recorded there was an accident owing to some old workings. Trusting the old plans, which showed a barrier 100 yards away, the miners worked into the old headings, with disastrous results. In another case, an inundation occurred, by which lives were lost, from a former working being cut into. In this instance there was a correct plan of the former work, but by a mistake of the surveyor, a wrong direction was set out.

Take a case from another class of mines, that of the asbestos mines of Canada. There, great mistakes, arising from a want of knowledge of mine-surveying, were made when the mines were first opened up, many thousands of tons of waste rock having, in several cases, been tipped on to some of the richest parts of the ground. This waste rock must unquestionably be again moved before that ground can be worked.

Fortunately errors such as these are not of every-day occurrence; whilst cases in which remarkable accuracy is obtained are frequent. The wonderful results obtained from the surveys of the Mont Cenis and St. Gothard tunnels, of the Croton aqueduct in New York, and of the Ernst August adit-level draining the mines of the Harz Mountains, I shall have occasion to refer to subsequently.

Probably the most difficult and most complicated mine survey ever executed was completed last year at Przibram in Bohemia. Here in 1875 the Adalbert shaft attained a perpendicular depth of 1,000 metres (3,280 feet). The same horizon, the 30th level, was reached by the Maria shaft, now the deepest shaft in the world, in 1879. In order to facilitate the haulage from this enormous depth, it was then decided to sink a third shaft to this level; but instead of sinking a new shaft from the surface it was decided to deepen an existing shaft, and the one selected was the Franz-Josef shaft, which at that time had reached the 17th level, a depth of 1,380 feet from the surface. In order to accelerate the construction of this shaft, it was arranged to work at five different levels by sinking and rising, and in each case the coincidence on junction was so exact that not the slightest change in the timbering or masonry was required. You will be able to form an idea of the magnitude of this survey, when I tell you that, in order to obtain the requisite data for the calculations, it was necessary to

survey eleven miles of underground roads and to set up the theodolite at 684 stations.

In the United States we find a striking example, showing how a knowledge of the principles underlying mine-surveying have, in a brilliant manner, been turned to profitable account. In the copper district of Lake Superior, the celebrated Calumet and Hecla mine had the good fortune to include within its original boundary lines the most important portion of the bed of copper-bearing conglomerate, which has been worked to a depth, measured on the incline, of 3,800 feet. The inclination being $37\frac{1}{2}°$, the greatest perpendicular depth is 2,310 feet. The extreme regularity of inclination and of value in the Calumet and Hecla bed induced the owners of a concession into which it was calculated that this bed would penetrate eventually, to sink a vertical shaft to cut the bed at this great depth. The shaft was sunk by the Tamarack Company with great rapidity to a depth of 2,275 feet, when the Calumet bed was cut in all its richness, and the Tamarack mine has ever since been a large producer of copper, success having crowned this extraordinary undertaking of sinking a hole half a mile into the earth with no positive assurance that there would be any return for the thousands of pounds expended.

Turning now to the history of surveying, we are told by Herodotus that the credit of making the first surveys is due to the Egyptians, who found need of the principles of geometry in the restoration of boundaries obliterated by overflows of the Nile. Recent discoveries made among the cuneiform inscriptions on terra-cotta tablets in the British Museum show, however, that the Babylonians preceded the Egyptians in the application of geometry to surveying. Boundaries were defined in Babylonia, as is still the case in mining claims, by means of corner stones. One of these boundary stones, preserved in the Museum, bears an inscription of the date of 1200 B.C. There is also a plan, with all dimensions figured on it, on a terra-cotta tablet, representing an estate of about 8 acres.

The origin of mine-surveying must be sought with that of mining in very ancient times. The oldest known plan relating to mining is a papyrus, which can be seen in the Museum at Turin. It depicts a gold mine in Upper Egypt, and was drawn in the reign of King Mineptah, 1400 B.C. The ancient mines represented are situated in the district known as Allaki, on the Red Sea, and have been described by Linant de Bellefonds Bey. They occur in two hills, about 100 feet above the valley level, in each of which there is a wide quartz vein. These two veins have numerous branches, which have been followed in all directions. The ancient workings are remarkable for their regularity and size. There are numerous vertical shafts sunk on either side of the two veins, the shafts being in communication by means of numerous levels. The excavations are of immense size, but fallen rock obstructs a large portion, and has prevented a thorough examination. Apart from the documentary evidence referred to, it is evident that these mines were not the work of the Arabs, but of the Egyptians under the Pharaohs. The Mahommedan Arabs have a dread of working underground. All the large mines of Lorah, which furnished the stone used in the construction of the pyramids, are immense excavations in the mountain, whilst all subsequent workings at the same locality are open quarries.

There can be no doubt that these gold mines were the penal settlements of the ancient Egyptians, as is shown by the following description, given 1900 years ago by Diodorus Siculus (Book 3, chap. xii.), a description which is almost identical with that given by Agatharcides at a still earlier date :—

"On the confines of Egypt and Æthiopia, towards the Arabian side, there is a place with many mines, especially of gold, which is raised in great quantities with great difficulty and expense. The earth is by nature black, and is traversed by strings and veins of stone of such remarkable whiteness as to surpass in brilliancy the most brilliant substances. Consequently those who have charge of the mines have to employ a great number of labourers to get the gold.

"Now the kings of Egypt send to work in the mines those who are convicted of crimes and prisoners of war, as well as those who have incurred the royal displeasure, sometimes singly, sometimes together with all their kindred; thus at the same time exacting punishment from the condemned, and deriving great revenue from their labour. Those who are sent there —and they are very numerous—are all bound with chains, and compelled to work all day and all night, without any rest or chance of escape; for they are guarded by pickets of foreign soldiers, who speak languages different from theirs, so that it is impossible for them to corrupt their warders by conversation or friendly association with them.

"When the earth which contains the gold is found to be too hard, it is split up by means of large fires, and then broken by hand. When the rock is so soft that it will easily yield to the pick, it is attacked by thousands of the convicts. The whole work is controlled by a skilled miner, who knows the veins, and gives instructions to the labourers.

"The strongest of those who are condemned to this unhappy fate break the white rock with iron hammers, bringing strength rather than skill to their task, and cut tortuous passages along the vein. These men, spending their lives as they do in darkness, owing to the turns and twists of the galleries, wear lamps attached to their foreheads. Changing their position as often as the nature of the place requires, they throw down the detached lumps of ore. And this task they continue unceasingly, urged on by the threats and blows of the overseer.

"The young children creep through the galleries to the openings made in the rock, and, carefully collecting the pieces of ore as they are thrown down, carry them to the mouth of the mine to the light of day. The men over thirty years of age receive from them a certain quantity of the ore, and pound it in stone mortars until they have reduced it to the size of a pea. The women and the oldest men receive from them the pulverised ore, and throw it into mills, of which there are several arranged in a row. Working at the handles by twos or threes, they reduce it to a powder as fine as flour.

"The remainder of the process is conducted by skilled workmen, who spread the powdered ore over a broad plank, slightly inclined, and pour water on it. The earthy matter is carried away by the water along the inclined plank, but that which contains gold remains on the wood by reason of its weight. This process they repeat several times. At first rubbing the material lightly with the hand, and afterwards pressing it gently with sponges, they remove the earthy matter until the gold-dust is quite clean.

"Finally, other skilled workmen take the gold by weight and measure and put it into earthen pots, adding, in proper proportion, lead, salt, a little tin, and some barley flour. Then fastening up the pots and sealing them with clay, they heat them in a furnace five days and five nights. Then having allowed them to cool, they find in the pots none of the added materials, but only the pure gold, with very little waste.

"Such is the vast labour expended on the extraction of gold in this district. And from this description I think it is clear that gold is hard to get, as it is difficult to keep; and though all men long to get it, yet, when they have it, they find as much pain as pleasure in the use of it." *

Turning to our own country, we find that an ancient charter exists of the date of Edward IV. (1408), which, in a rude attempt at plan drawing, curiously represents the "Myne deeps," as they were then called. This document, of which a facsimile is given in Robert Hunt's "British Mining," contains a considerable amount of information. The dogs hunting signify that the Mendips were a royal chase, and therefore preserved by the Sovereign. The churches signify so many parishes. The chief mines are correctly placed, and the marginal drawings convey a fairly good idea of the mining methods employed at this date.

* For this translation I am indebted to the Rev. Arthur Chilton, M.A.

The methods of mining then in vogue are also well shown in the pieces in the ceremonial collar used by the senior member of the goldsmiths at Ghent. This collar is made in 15th century chased silver, and the mode of conducting a mine survey is shown in the first panel.

The ancient mine surveyors strenuously endeavoured to keep their art a secret. In the Middle Ages they were, in consequence, superstitiously regarded as sorcerers. The divining rod was closely associated with the practice of their profession, and, in many cases, was trusted more implicitly than the most scientific survey.

The extent to which this rod is still used for the detection of mineral deposits, springs, or hidden treasure, is much greater than educated persons would be likely to suppose. The mining journals frequently announce that adepts with this instruments are exploring for mineral veins in different parts of the world. The records of the Patent-office show that numerous forms of divining rod have been patented of late years. The *Daily Graphic* of March 11, 1891, illustrated a divining-rod expert, pointing out, at the request of the Grantham Union Sanitary Authority, sources from which supplies of water might be obtained. The *Daily News* of March 24, 1892, contains an account of explorations for water made with the divining rod, under the auspices of the Northamptonshire County Council; and the *Globe*, of March 28, contains a testimonial to the efficacy of the divining-rod from the pen of a Doctor of Divinity. These circumstances, taken together with the fact that the "dowsers," or experts with the rod, still find numerous supporters in Cornwall, in Germany, and in the Western United States, certainly justify me in regarding this subject as one not merely of antiquarian interest. Yet, a consideration of the history of the divining rod, as summarised by Chevreul, Louis Figuier, and Dr. Rossiter Raymond, clearly shows that the phenomena presented by it must be regarded as being due to self-delusion, deliberate deceit, or involuntary mendacity.

Before referring to the history of this instrument, I should like to say a few words about its form, material, and use. This,

however, is a work of great difficulty, inasmuch as the literature of the divining rod shows nothing more clearly than the contradictions of its advocates. Indeed, an old German author, Theophilus Albinus,* writing in 1704, quaintly observes: "I ween that no more confounded thing is to be found in the world than this divining rod business; for what is right and fit to one is wrong and unfit to many others, so that out of such great confusion not much good is to be presumed. For evil and lying dealings are best hidden amid this confusion, and in the muddiest water rascality likes best to fish."

The most common divining rod has always been a branch of hazel, in the shape of the letter Y. This is held in the two hands, each grasping the extremity of a prong, with the fingers closed not too tightly and the palms upwards. When carried in this manner by the adept, the rod is said to dip above mineral deposits, springs, or treasure. Though the Y-shaped rod is the most common, other shapes and materials have been advocated at different times. Thus, in a work published in 1700, by J. G. Zeidler, entitled "Pantomysterium, oder das neue vom Jahre in der Wündschelruthe als einem allgemeinen Werckzeuge Menschlicher verborgen Wissenschafft," instructions are given in the use of a great variety of instruments as divining rods, tongs, scissors, snuffers, books, the fore fingers, and so on. Indeed, the last instrument of this kind patented (British patent 1889, No. 1919) consisted, not of a rod at all, but of a flask filled with a composition of gold, silver, copper, quicksilver, and an acid or alcohol. It is suspended from one hand by a cord, and steadied by the other. If there is precious metal in the neighbourhood, it is stated that the flask will vibrate.

All authorities agree that the rod will turn in one man's hand and not in another's. It is said that a sympathy must be established between the holder, the rod, and the metal, and that many persons are wanting in the necessary qualities, whatever they may be. But how can it be explained that the rod, even in the right holder's hand, will not turn over unconcealed metal? Here you have all the conditions, but all authorities agree that the rod will not work over uncovered metal or over an open brook.

In France, in the time of Louis XIV., the rod was used for detecting criminals. The case of the murder at Lyons in 1692 is almost too well known to be quoted. A wine merchant and his wife were murdered. The authorities, who seem to have had no clue to the murderers, employed a peasant to wield the rod. He followed with the rod the alleged track of the fugitives, and finally, at the prison at Beaucoire, pointed out as one of the murderers, a hunchback recently arrested for larceny. This man confessed his guilt, and was broken on the wheel. This discovery by the aid of the divining rod seemed indeed marvellous; but later investigations have shown that it was merely a piece of clever detective work.

Ninety years later, in Paris, Bartholemy Bleton created a great sensation as a water-diviner. He is said to have followed, in the presence of crowds of spectators, a subterranean aqueduct in the Luxembourg gardens for 1,500 yards without a mistake, and the engineer of the works is reported to have said that if the plans in his possession had been lost, Bleton's footsteps would have constituted a complete survey to replace them. Later trials, however, did not give such remarkable results. Bleton would often pass over running water, when blindfold, without noticing it, and when taken several times over the same course, he would not point out accurately each time the spots which he had previously marked.

FIG. 1.

Turning to the use of the divining rod in tracing mineral veins, we find that Dr. Pryce, the early authority on Cornish mining, was a firm believer in the rod, and he devotes several pages of his book ("Mineralogia Cornubiensis," London, 1778) to instructions

* "Das entlarvete Idolum der Wunschel Ruthe," Dresden, 1794, p. 88.

in its use. An earlier writer on mining matters, William Hooson ("The Miner's Dictionary," Wrexham, 1747), is more sceptical, and he notes that "the Dignified Author of this Invention was a German, and that at the last he was deservedly hang'd for the Cheat." Agricola, the author of the first systematic treatise on mining ("De re Metallica," Basel, 1556), cautions miners against the use of the rod. The miner, he says, as a good and sober man should not use the enchanted rod, because he knows by observation the indications of nature, and to him therefore the rod is of no use. In the woodcut (Fig. 1, p. 803) illustrating this passage, a miner in the background is represented cutting his twig, while another is proceeding with it in due form to a spot where two "good and sober" miners have already found ore by digging.

An interesting old German mining token is known to numismatists, in which Cupid is represented as a "dowser" in a miner's hat and a long miner's leather, with his quiver by his side, proceeding in the orthodox manner with the divining rod. Above is written, "Ruthe weise glücklich an." On the obverse Cupid is sitting before an anvil engaged in coining, the inscription being "Dass ich aus beüt müntzen kan." The date of this silver token is 1719.

In the early works on mine-surveying, the divining rod is treated just as an ordinary surveying instrument. Thus August Beyer, who published a treatise on mine-surveying at Schneeberg, in 1749, devotes two chapters to the use of the rod, even describing its application to the solution of surveying problems. For example, if it was required to sink a perpendicular shaft to intersect the end of a level where a miner was working, a piece of the miner's leather apron was cut off and placed in the divining rod expert's hand, and where the rod dipped would be the correct place for sinking the shaft.

It is curious that we hear so little of the divining rod as we do in the religion and folklore of antiquity. Even Pliny, who never omitted to mention a superstition that came in his way, seems never to have heard of the divining rod. The theory that the divining rod was originally "made in Germany" would therefore appear to be correct.

Dr. Rossiter Raymond, in his masterly paper on the divining rod, forcibly sums up the matter thus:—"In itself it is nothing. Its claims to virtues derived from the Deity, from Satan, from affinities and sympathies, from corpuscular effluvia, from electric currents, from passive perturbatory qualities of organo-electric force, are hopelessly collapsed and discarded. A whole library of learned rubbish, which remains to us, furnishes jargon for charlatans, marvellous tales for fools, and amusement for antiquarians."

Those who wish to study what is known about this wonderful twig should refer to M. E. Chevreul, "De la baguette divinatoire," Paris, 1854; L. Figuier, "Histoire du merveillex dans les temps modernes," vol. 2, Paris, 1860; R. W. Raymond's paper on the divining rod, read before the American Institute of Mining Engineers in 1883; and report on wells sunk at Locking, Somerset, to test the alleged power of the divining rod, by Professor W. J. Sollas (Journal of the Psychical Society, 1884). In the library of the Museum of Practical Geology, there are two curious old French tracts: "La verge de Jacob, ou l'art de trouver, les tresors, les sources, les limites, les metaux, les mines, les mineraux et autres choses cachés, par l'usage du baton fourché," by J. N., Lyons, 1693; and "Traité en forme de lettre contre la nouvelle rhabdomance ou la maniere nouvelle de deviner avec une baguette fourchuë," Lyons, 1694.

In California there have been mineral prospectors claiming to be natural magnets, and not using the divining rod. But they do not appear to have met with any better results. One of these natural magnets was employed to trace a lost vein at a mine in the Grass Valley. Under his direction the company cut for many hundred feet, at a cost of £6 to £8 per foot, through serpentine rock, although this belt was exposed, and known to be barren in the immediate vicinity.

More important and legitimate is the use of the magnetic needle in the exploration for iron ore. The needle, in this case, affords valuable aid, and has been largely used in Sweden and in the United States. The theory of its use is based on the fact that certain ores become magnetic by induction under the influence of the earth's magnetism. By noting the dip of the magnetic needle, the extent of an iron ore deposit can be ascertained. Indeed, Professor Le Neve Foster records a case in which an iron ore deposit, shown on a Swedish map to exist under a lake, had been mapped in winter by observations made on the ice. Compass explorations in the United States and in Sweden being in many instances the sole source of income, you will readily understand that a skilful operator may wish to keep his

mode of procedure a secret. Frequently, therefore, the supposed supernatural properties of the divining rod are transferred to the compass. This excess of faith in some is accompanied by scepticism in others. For this, unfortunately, there are good grounds, the compass being so admirably adapted for dishonest purposes. The case is recorded of an American prospector whose compass needle, in the vicinity of an ore mass, always showed a dip of 90° when facing west, and the true dip due to local attraction when facing east. The former position, it is said, was very successfully used in selling iron ore grounds, and the latter in buying them. Similarly, in Sweden, a powerful magnet, inserted in a walking-stick, has been successfully employed to give a large dip to the needle when it was thought advisable to mislead the purchaser.

Of late years, purely scientific methods of exploring for iron ore with the magnetic needle have been introduced, and in this way important deposits have been discovered in Sweden; whilst in New Jersey, in six years, the annual production of the State increased 50 per cent. by the addition of new producing localities found by the compass.

In illustration of this lecture, there were exhibited a divining rod, a Swedish compass, and an American compass, used for exploring for iron ore.

Miscellaneous.

PRODUCTIONS OF BRITISH HONDURAS.

The following particulars and suggestions relating to the opening up and improvement of the commercial interests of British Honduras are taken from the speech of his Excellency Sir Alfred Moloney, K.C.M.G., Governor, to the Legislative Council of the Colony on 25th March last:—

"The commercial prosperity of colonies which depend on one or a limited number of articles of export is liable to disastrous fluctuations. Striking instances are to be found in the ruin of a once extensive trade, that had been confined to a single commodity, from competition and the inevitable fall in price, the ravages of rats or locusts, or a single blight. So far British Honduras would seem to have stood exceptionally in the Colonial Empire in having, for most of its history, the past two centuries, leaned for its existence almost entirely upon nature, both as regards its forest produce and rivers, as means of transport to the sea. Some of our West African possessions have stood somewhat similarly since palm oil succeeded the slave export trade; that industry is now seriously threatened by animal fats and other sufficiently available and equally suitable commodities. One of the extracts from coal tar practically killed the once flourishing and profitable cochineal trade, and also affected the indigo trade of India. Beet has contributed to the depression of the sugar trade. The substitution of iron for wood in shipbuilding, particularly in men-of-war, almost killed the large timber export trade of the Gambia and West Africa, which is also noted for its mahogany, cedar, rosewood, dye, and other woods; the marked and progressive revival of that trade, and the dimensions it is assuming, must naturally be a subject of direct concern and anxiety to all wood-cutting centres. Mahogany and logwood trees have stood prominently for several generations the commercial idols of these parts, but they are said to be getting more and more difficult of access, and, consequently, more expensive to work and get to the market.

"I do not, for one moment, question the appreciation that has been rightly, and should continue to be, extended to those valuable industries. On the contrary, I entertain every desire to promote them and to protect our forests on which they depend, a subject which, among others, occupies my attention. You will, I am confident, agree with me that the colony's motto, 'Sub umbra floreo,' should have now a more extended application.

"In view, however, of such experiences as I have referred to, it has been, I think, generally accepted that even in commerce it is a hazardous experiment to 'carry your eggs in one basket,' and, I may add, be sure, even with a wider distribution, that they have a commercial value when you take them to market, for, to guide us in establishing profitable industries we should reasonably look to the field or source of supply, the prospects and disposal of growth, and the area of the field of demand. It has become consequently part of the general Colonial policy to encourage the production of varied staple articles of export of a more or less permanent character. In such a direction, more especially in agriculture, much has been done by the active interest and assistance of the authorities of the Royal gardens at Kew to develop new industries and to distribute plants of commercial importance. In furtherance of such views, we see established, in all our West Indian possessions, botanic stations. Surely the time has come for a similar erection in this colony, which has such exceptional advantages, whether we look to climate, soil, or a market. It has been with some justice advanced that British Honduras can be made the tropical garden of North America, and why? Well 28° North is generally accepted as the frost line which may be said to mark the limit northwards, within which the growth of economic products in demand can be profitably undertaken.

"And again, as to fertility of soil, what more convincing proof can be advanced than the facts

that in the sugar areas to the north and south of the colony cane has been known to "ratoon" from 20 to 30 years, and that in the rich and naturally fertilised valley beds, bananas have repeated themselves without degeneration for 10 to 12 years, if not longer.

"The products of our cultural industries, still really in their infancy, are chiefly represented by bananas, plantains, cocoanuts, coffee, henequen—Indian corn—limes, mangoes, oranges (sour and sweet), pineapples, avocado pears, rubber, to which there should be added in time, arnatto, cacao, coir, ground-nut, indigo, jute, pita, ramie, spices, vanilla, and doubtless other promising marketable commodities.

"Even to the small extent to which the banana has been successful to the north of the frost line, where it will always be a precarious crop at best, it has proved inferior in quality to the West Indian and Central American fruit, and affords further proof that adaptability of climate does not assure profitable crops. Whilst in 1879 it did not appear among our records, its export was represented by 472,436 bunches in 1891.

"The plantain is a staple of food over a large section of negroland in West Africa. The descendants of its interesting people to the north of the Gulf of Mexico represent a consuming power of nearly 9,000,000, if the coloured population there have shown by 1890 the same growth it did for the decade which ended in 1880. Tons of this fruit from Cuba and Jamaica meet with a ready sale in Florida. Our shipments to New Orleans rose from 50,000 plantains in 1879 to 1,580,200 in 1891.

"The home of the cacao is Central America. Several valuable species are said to belong to British Honduras, and include that which is said to be the best in a marketable sense. Notwithstanding, it may be said to be here remarkable by its absence from the export cultures of the colony, which have grown in value—in round numbers—from $12,000 in 1879 to $296,665 in 1891, yet in the island of Grenada, of the West Indies, and but 5° to 6° to our south, and with an area of 133 square miles, and an estimated population in 1889 of 50,000, cacao has developed into its main export, which reached, in 1890, a value of £228,319.

"The clover-light ground nut, so desirable as a pasture where the bread-nut is not available, apart from its valuable tuber, and henequen would seem to be admirably suited for growth in the pine ridges. That interesting orchid, the vanilla, whose home is also in Central America, is one of the most valuable products, and has near to hand a rich and ever growing market. Its cured pod fetches as much as 30s. per lb. It is a plant easily propagated by means of cuttings, and has developed into a considerable export from Vera Cruz.

"Our neighbours seem to turn no small attention to the cultivation of the coffee arabica. Whilst it will doubtless prove suitable to the high areas of the colony, the introduction of the hardy and rich Liberian coffee so well suited to low-lying areas, with its comparatively heavier crop, averaging from 6 to 8 lbs. per tree, 400 of which can be accommodated on each acre, should receive the consideration it deserves. Judging from the exports from India, and the imports into the United States, there is a promising field of demand offered in the latter direction for the growth of such commodities as jute and other fibres, indigo, ginger, and spices generally.

"The cohune oil industry remains yet dormant, if I except the use for domestic and cooking purposes to which it is put among the families of mahogany and logwood cutters. Two-fifths of the colony, viz., 1,933,762 acres are, it is estimated, under this graceful palm. If we allow 25 trees to the acre, a very low average, and 1,000 nuts as the annual yield per tree, and accept that 100 nuts yield a quart of oil, this dormant industry, if awakened to full activity, would yield 276,537 tons of oil at a price per ton appreciably above that which obtains for cocoanut oil, to which it is superior.

"Then again, apart from its resinous property, which was turned, I understand, to profitable account some years back, the pine, it is estimated, covers a third of the colony, or 1,613,136 acres, and averages 100 trees per acre on our great southern pine-ridge, much more in other parts. Its wood is said to almost equal that of the yellow pine of the United States, which, in the beginning of 1888, was reported to have been nearly worked out, and might, in part, have to be re-placed by the local pine. The growth on the older pine-ridges of the colony may, when opened up, prove of sufficient age and diameter to make it worth while to have attention turned to adding this timber to our exports, as can doubtless be done with many other valuable woods unknown yet to science as well as to wood fairs.

"In Scandinavia, apart from its extensive export as a wood, from its wide use in the manufacture of matches, or from the value of its resinous properties, the pine pulped has been most profitably utilised in the manufacture of a commodity that has developed into an important rival to paper.

"The coral patches and marine islets we know as 'Cays' that fringe, to their eastward, the waters of this colony, offer a condition of site exceptionally favourable for the growth of henequen and the cocoanut trees, described as the most tender of palms as regards frost, the friend of tropical agriculturists. The area of such Cays is given approximately as 112,527 acres, which might be turned to much more profitable uses and yield than obtain at present. With even a quarter of such acreage suitable for the culture of such products as cocoanuts and henequen, it could be covered with plantations of the former, numbering 2,813,200 trees, with an annual yield of at least 100 nuts (a low average), aggregating 281,320,000, worth, at the current rate per thousand, £1,406,600, and in a condition clear of the fibrous exterior that yields the coir of commerce, here usually thrown away or associated occasionally

with mahogany chips and conch shells to fill up low-lying lots. Now I should explain that such an aggregate of nuts, on the basis of 1 lb. from seven nuts or 14 per cent. fibre, should yield 18,000 tons fibre that would realise in the London markets from £30 to £10 per ton, dependent whether suited for brushes, mats, or stuffing.

"The annual export from the colony of cocoanuts during the past five years has averaged in number 1,651,933, and in value $32,505.

"That delicious fruit, the sapodilla, if picked green, will stand shipment. The tree abounds in this colony, and apart from its valuable and durable wood, yields an extract which contributes mainly to the manufacture of what is advertised and so widely used in the United States as "chewing gum."

"Then, again, trees yielding the pimento of commerce abound in a wild and unappreciated state, yet this spice was of the value of £81,328 for the year 1890-1 to Jamaica as an article of export.

"Local prospects and foreign demand seem sufficiently encouraging to justify the establishment in these waters, on a stable and profitable basis, of a sponge industry. Varieties, ranging from yellow, or "grass," to "sheep's wool." are said to be identical with those of the Bahamas and of Florida, which fetch from 25 cents. to $1.20 per lb. in United States currency. Exhibits from British Honduras at the Colonial and Indian Exhibition of 1886 attracted marked attention, and were pronounced as excelling in quality contributions from neighbouring and established areas.

"The Bahama industry, which is said to have begun about 1842, has grown to be worth, approximately, £60,000 per annum. In 1852 it was followed by Florida, and with about the same monetary result. There some 6,000 spongers of Bahama origin, born and bred to the work, are employed over an area of about 3,000 geographical miles, or 2,208,920 acres. The area of the marine waters of this colony has been returned as 2,464,000 acres, and while I am not prepared to say that our virgin sponge grounds are co-extensive with such acreage, sufficient proof has been experimentally afforded to justify the conclusion that rich crops are locally available, and only await to be reaped.

"As you are aware, the survey for a line of railway to the frontier of the colony proceeds; the circumstances and conditions thereof have been publicly notified. The result, together with the expression of the local views thereon, which will be invited, should help materially to guide the decision whether or not this colony can, in the near future, undertake such an enterprise which, it is generally acknowledged, is essential to open up the locked-up Crown lands to the south and west that have been for generations and are practically a *terra incognita*, and likely to remain such without a railway; to encourage, further, the introduction of capital and labour; to tap and afford means of transport to rich timber areas hitherto if not unapproachable, at least unworkable, from their inaccessibility; to promote in our rich and naturally fertilised valleys the extension of small economic cultures and general agricultural industries; to develop the mineral resources of the colony in the only direction in which prospecting has so far looked with favour; and to enable our Hinterland to be reached, the climatic conditions of which will admit, it is advanced, of foreign and indigenous settlement."

PRODUCTION OF PLATINUM IN RUSSIA.

The platinum beds of the Ural mountains, according to the *Journal de la Chambre de Commerce de Constantinople*, are the only ones in the world in which this metal is found in grains. Platinum is found in Brazil and in the Cordilleras in the hard serpentine rocks, but never in the form of grains. The platinum beds of the Ural mountains are found in various districts. In the north, at Besserski, in the government of Perm, in the district of Khotourski, and in the State properties of Goroblagodatski, where sixty-six mining concessions have been granted. All the beds of the northern region are situated in the basin of the River Touri, in that of the tributory stream of Taghil, and in other tributaries higher up. On the western declivity of the Ural mountains there is another platinum bed near the River Outka, a tributary of the Tchoussova, and the basins of the higher tributaries of the Outka, near the Ural river. The platinum found in these places is in the form of grains, in sand frequently containing gold. The weight of these grains is from 17 to 21 grammes to every 1,640 kilogrammes of sand. The richness of the platinum beds varies in the same proportions. In some, the thickness of the turf covering the sand does not exceed from 2·16 metres to 2·88 metres, while in others it varies from 10·80 metres to 14 metres, so that it becomes necessary to work underground. The thickness of the platinum sands does not vary much. A noticeable characteristic of it is that they are found in the form of friable grit, and easily washable. The clayey sand is rarely met with. The beds in the northern districts of the Ural mountains are most frequently of little depth, thus allowing the turf to be easily removed and the platinum is quickly reached. The platinum found in this district contains a considerable proportion of gold, whereas that found in the Taghil district contains hardly any. Moreover, the Northern platinum and that of the Taghil district are very different in appearance. The former appears clear and very brilliant, while the latter is of a dull colour and is frequently found mixed with rare metals such as iridium and osmium. The size of the grains is about the same in the two beds. The demand for platinum for industrial purposes is relatively restricted, as it only dates from the last twelve or fifteen years. It is largely used for electric lighting and dynamo con-

ductors, and considerable quantities of platinum are now employed in chemical and other factories. During the last twelve years the annual production of platinum has averaged about 3,194 kilogrammes, of which half has been derived from the beds in the north of the Ural mountains belonging either to the State or to private persons. Throughout the whole world only about 3,270 kilogrammes of platinum are annually used, but it is anticipated that this amount will soon be considerably increased, and it is stated that the platinum beds of Bisserski can alone supply the total quantity required for the consumption of the world. When the demand for platinum was insignificant and the price very low, the gold miners who found platinum while seeking gold, frequently, it is stated, used the former instead of lead, as shot for firing at wild birds. It is only since the demand has increased that greater attention has been paid to this metal. All the platinum extracted from the Ural mountains, after having paid a tax of 3 per cent. in kind, is sent as raw ore to St. Petersburg for treatment and shipment to foreign markets.

SERICULTURE AT ADRIANOPLE.

The following information respecting sericulture in the vilayet of Adrianople, from the *Journal de la Chambre de Commerce de Constantinople*, is quoted from the *Board of Trade Journal*:—

"It is within a radius of from 30 to 40 kilometres around the town of Adrianople, the chief town of the province of the same name, that the rearing of the silkworm offers the greatest interest and where the chief centre of the production is found. Some other localities, at some distance from the chief town, also produce cocoons, but in small quantities; these villages are chiefly situated on the shores of the Sea of Marmora and on the Rodhopes mountains.

"For some years the production of the district of Adrianople has reached 500,000 okes of fresh cocoons, about 70 per cent. of which are yellow and the remainder white.

"The yield of cocoons from eggs placed for hatching is estimated at 20 okes per box of 30 grms. There are in the province 20,000 boxes, of which 15,000 of the yellow breed come from France, and 5,000 of the white Bagdad breed imported from Broussa; these eggs produce altogether 400,000 okes of cocoons. There are also produced 100,000 okes of cocoons coming from eggs obtained in the country by the breeders themselves, which are not placed for sale.

"The silkworms' eggs are not sold for ready money, but according to what they may yield. It almost always happens that more eggs are imported than are required; the egg-dealers therefore, in order that their boxes may not be wasted, offer them at ridiculous terms, and thus carry on between themselves a keen competition from which alone the peasant profits. It therefore follows that the profits of the egg-dealers from the yield of the cocoons is almost *nil*. A reasonable rate on placing the seeds is from 20 to 25 per cent. on the product, but 12½ and 10 per cent. are finally granted.

"The silk industry of the country is carried on by two spinning mills, requiring for their annual needs about 150,000 okes of fresh cocoons.

"There remains, consequently, from the total of the crop 350,000 okes of cocoons for export; but this figure is reduced to 300,000 by the process of testing, which is carried out before export, for about 50,000 okes of broken cocoons remain in the country, and are woven into common silk for local consumption.

"The cocoons thus tested are sent to Marseilles and Milan. Yellow are preferred in Italy and white in France, where their sale is easier by reason of the special uses to which they are put."

Obituary.

CYRUS FIELD.—Mr. Cyrus West Field, the successful promoter of Atlantic cables, who died at New York, on Tuesday, 12th inst., was elected an honorary life member of the Society of Arts in May, 1876, "for his valuable services in connection with the promotion of electric communication between England and America." Mr. Field was born at Stockbridge, Massachusetts, on November 30th, 1819, and on leaving the school of his native town he became a clerk in New York; soon afterwards he started a business on his own account, from which he retired in 1853. He now devoted his whole attention to the promotion of ocean telegraphy. In the pursuit of this object he is said to have crossed the Atlantic about fifty times. His first venture was the construction of a line from the coast of Ireland to that of Continental America by way of Newfoundland. He received the unanimous thanks of Congress with a gold medal in commemoration of his successful enterprise.

LORD WINMARLEIGH.—The Right Hon. John Wilson Patten Lord Winmarleigh, who died on Monday, 11th inst., at his seat, near Garstang, North Lancashire, had been a member of the Society of Arts for 40 years. He was born in 1802, and educated at Eton and Magdalen College, Oxford. After three years of travel on the Continent, he was elected, in 1830, one of the members for Lancashire. From 1832 to 1874, Colonel Wilson Patten represented North Lancashire in the House of Commons. He was Chairman of Committees of the whole House from November, 1852, till April, 1853; Chancellor of the Duchy of Lancaster from June, 1867, to September, 1868, and Chief Secretary for Ireland from September to December of the latter year. He was created Baron Winmarleigh in 1874.

Journal of the Society of Arts.

No. 2,070. Vol. XL.

FRIDAY, JULY 22, 1892.

All communications for the Society should be addressed to the Secretary, John-street, Adelphi, London, W.C.

Chicago Exhibition, 1893.

EXECUTIVE COMMITTEE.

A meeting of the Executive Committee was held on Wednesday, 20th inst. Present: Sir Frederick Abel, K.C.B., D.C.L., D.Sc., F.R.S., in the chair; Alfred Carpmael, James Dredge, and Sir Douglas Galton, K.C.B., D.C.L., F.R.S.

KARACHI COMMISSIONER.

The Secretary has received information from Mr. James Currie, President of the Karachi Municipality, that Mr. Jehangir H. Kothari, a Member of the Municipal Corporation of Karachi, has been delegated to represent the Municipality at the Exhibition.

Proceedings of the Society.

CANTOR LECTURES.

MINE SURVEYING.

By Bennett H. Brough, Assoc.R.S.M., F.G.S.

Lecture II.—Delivered April 4, 1892.

Lengths in collieries are measured with the chain of 100 links, each link, with connecting rings, measuring 7·92 inches. The whole length of the chain is thus 66 feet. At each 10th link is a brass teller, so shaped that it indicates the number of tens. This odd length was selected by the inventor, Edmund Gunter, Professor at Gresham College, in 1620, in order to supply the surveyor with the basis of a decimal notation. An acre measures 4,840 square yards, and the square of 22 is 484; consequently, a square chain is 1-10th of an acre, and 10 square chains equal one acre. By the employment of this unit, acreage calculations, to determine the area of coal wrought, can be readily effected.

In metalliferous mines, the unit of length usually adopted is the fathom of 6 feet; and the chains employed are generally 10 fathoms in length, divided in 6-inch links. In the Continental mines, the metre is now the general unit of length. The most accurate measurements are made with a steel band, a delicate instrument that necessitates careful usage. In America these bands are made of great lightness, and measurements are expressed in feet and decimals of a foot.

It is interesting to compare these perfect methods of measuring lengths with those formerly employed. In an old German work on surveying, by Jacob Koebel, published in 1570, a copy of which can be seen in the British Museum, the unit of length is described somewhat as follows:—"A rood should, by the right and lawful way, and in accordance with scientific usage, be made thus: Sixteen men, short and tall, one after the other, as they come out of church, should place their left feet in a line; and if you take a length of exactly 16 of these feet, that length shall be a true rood, with which you may measure fields." This description is accompanied by a quaint illustration, showing the process being put in operation.

In the construction of mine plans the scale adopted depends on the extent of the property. For collieries of moderate size, a scale of 2 chains to the inch (1 to 1,584) is found useful; whilst scales of 3 chains to the inch (1 to 2,376) or of 4 chains to the inch (1 to 3,168) are adopted for larger properties. Besides these, the Ordnance scale of 25·44 inches to the mile (1 to 2,500) is sometimes used. With this scale the necessity of preparing a surface plan is obviated, and there is the advantage that a square inch represents an acre. At a few large collieries the workings are also represented on the Ordnance map of 6 inches to the mile (1 to 10,560), so that the whole area and system of working can be seen at a glance.

For the plans of metalliferous mines in this country no scale is prescribed by law, and the variety of scales used presents great difficulties with regard to the comparison of the plans of different neighbouring mines. Scales of 4 fathoms (1 to 288) and of 8 fathoms to the inch (1 to 576) are perhaps the most usual.

The most accurate mine surveys that I have ever met with are those of the Pennsylvania anthracite mines. The law in that State re-

quires plans of all workings on a scale of 100 feet to the inch (1 to 1,200). This scale is rather too large for convenient reference, and working plans are frequently constructed on a scale of 200 or 300 feet to the inch. These plans show all the important surface features, buildings, streams, roads, and railways, as well as the underground workings, the latter being usually drawn in blue, red, or green ink. When several seams are worked, the workings on each seam are shown in a separate colour, this precaution being especially necessary where the workings on one seam are directly above those on another. Besides the general plan, other plans showing the workings on each seam are usually made, and blue-prints of these are furnished from time to time to the underground manager.
